The More Data subfield shall be set to 1 in the headers of all but the final frame containing one of these buffered non-GCR-SP group addressed BUs to indicate the presence of further buffered group addressed BUs. If the AP is unable to transmit all of the buffered non-GCR-SP group addressed BUs before the non-STBC or STBC TBTT following the DTIM, the AP shall set the bit for AID 0 (zero) in the TIM element to 1 for a single BSSID or set the corresponding group addressed bit to 1 for multiple BSSIDs, as defined in 9.4.2.6, and when dot11FMSActivated is true, shall set the appropriate bits in the FMS Descriptor element as described in 9.4.2.75 to indicate for which non-GCR-SP group addresses there are still buffered BUs, until all buffered non-GCR-SP group addressed BUs have been transmitted.

When the AP transmits an STBC DTIM or TIM Beacon frame, the AP shall retransmit all non-GCR-SP group addressed BUs that were transmitted following the non-STBC DTIM or TIM Beacon frame except that they are transmitted using the basic STBC MCS. It may be the case that a complete set of buffered non-GCR-SP group addressed BUs is sent over a period of time during which non-STBC and STBC transmissions are interleaved, but the transition from non-STBC group addressed transmissions to STBC group addressed transmissions shall be preceded by the transmission of a STBC Beacon frame and the transition from STBC group addressed transmissions

to non-STBC group addressed transmissions shall be preceded by the transmission of a non-STBC Beacon frame.

- f) Buffered BUs for STAs in the PS mode shall be forwarded to the CF-Pollable STAs under control of the PC. Transmission of these buffered BUs as well as CF-Polls to STAs in the PS mode that were indicated in the DTIM in accordance with paragraph c) of this subclause shall begin immediately after transmission of buffered non-GCR-SP group addressed frames (if any), and shall occur in order by increasing AID of CF-Pollable STAs. A CF-Pollable STA for which the TIM element of the most recent Beacon frame indicated buffered BUs shall be in the awake state at least until the receipt of an individually addressed frame from the AP in which the Frame Control field does not indicate the existence of more buffered BUs. After acknowledging the last of the buffered BUs, the CF-Pollable STA operating in the PS mode may enter the doze state until the next DTIM is expected.
- g) An AP shall have an aging function to delete pending traffic buffered for an excessive time period. The exact specification of the aging function is beyond the scope of this standard.
- h) When an AP detects that a CF-Pollable STA has changed from the PS mode to the active mode, then the AP shall queue any buffered BUs addressed to that STA for transmission to that CF-Pollable STA as directed by the AP's PC.

11.2.3.8 Receive operation for STAs in PS mode during the CP

A STA in PS mode shall operate as follows to receive a BU from the AP when no PC is operating and during the CP when a PC is operating.

The following rules describe operation of a STA in PS mode during the CP:

- a) The STA shall wake up early enough to be able to receive the first Beacon frame scheduled for transmission at the time corresponding to the last TBTT for which the STA was awake plus the time interval indicated by the ListenInterval parameter of the MLME-ASSOCIATE.request or MLME REASSOCIATE.request primitive.

NOTE—The STA might wake for a TBTT that is earlier than this deadline. In that case the previous requirement is reset based on a new “last TBTT”.
- b) When the STA detects that the bit corresponding to its AID is 1 in the TIM, the STA shall issue a PS-Poll frame, or a trigger frame if the STA is using U-APSD and all ACs are delivery-enabled, to retrieve the buffered BU. The PS-Poll or trigger frame shall be transmitted after a random delay uniformly distributed between zero and aCWmin slots following a DIFS.
- c) The STA shall remain in the awake state until it receives the BU in response to its poll or it receives another Beacon frame whose TIM indicates that the AP does not have any BUs buffered for this STA. If the bit corresponding to the STA's AID is 1 in the subsequent TIM, the STA shall issue another PS-Poll frame to retrieve the buffered BU. When a STA that is using U-APSD and has all ACs delivery-enabled detects that the bit corresponding to its AID is 1 in the TIM, the STA shall issue a trigger frame or a PS-Poll frame to retrieve the buffered BU.
- d) If the More Data subfield in the MPDU(s) containing the BU indicates that more traffic for that STA is buffered, the STA, at its convenience, shall poll until no more BUs are buffered for that STA.
- e) When dot11FMSActivated is false and ReceiveDTIMs is true, the STA shall wake up early enough to be able to receive either every non-STBC DTIM or every STBC DTIM sent by the AP of the BSS. When dot11FMSActivated is true and ReceiveDTIMs is true and the STA has been granted by the AP an alternate delivery interval for a multicast stream, the STA shall wake up before the non-STBC DTIM or STBC DTIM having Current Count of FMS Counter field set to 0 for that particular FMS stream.

A STA that stays awake to receive group addressed BUs shall elect to receive all group addressed non-STBC transmissions or all group addressed STBC transmissions and remain awake until the More Data subfield of the appropriate type (non-STBC or STBC) of group addressed BUs indicates

there are no further buffered group addressed BUs of that type, or until a TIM is received indicating there are no more buffered group addressed BUs of that type, or until an FMS Descriptor element is received indicating that there are no further buffered group addressed BUs for which the STA has previously received an FMS Response element in a frame that has a value in Address 1 that matches its MAC address or that has an Address 1 value that is a group address corresponding to a group of which it is a member and that was transmitted by the AP with which it is associated and which had an Element Status value in the FMS Status subelement of “Accept”. If a STA receives a QoS +CF-Ack frame from its AP with the More Data bit equal to 1, then the STA shall operate exactly as if it received a TIM with its AID bit equal to 1. If a STA has set the More Data Ack subfield in QoS Capability element to 1, then if it receives an Ack frame from its AP with the More Data bit equal to 1, the STA shall operate exactly as if it received a TIM with its AID bit equal to 1. For example, a STA that is using the PS-Poll delivery method shall issue a PS-Poll frame to retrieve a buffered BU. See also 10.3.6.

11.2.3.9 Receive operation for STAs in PS mode during the CFP

A STA in PS mode that is associated as CF-Pollable shall operate as follows in a BSS with an active PC to receive BUs from the AP during the CFP:

- a) The STA shall enter the awake state so as to receive the Beacon frame (which contains a DTIM) at the start of each CFP.
- b) To receive group addressed BUs, the STA shall wake up early enough to be able to receive either every non-STBC DTIM or every STBC DTIM that may be sent during the CFP. A STA receiving group addressed BUs shall elect to receive all group addressed non-STBC transmissions or all group addressed STBC transmissions and remain awake until the More Data subfield of the frames containing the group addressed BUs indicates there are no further buffered group addressed BUs of that type, or until a TIM is received indicating there are no more group addressed BUs of that type buffered or until an FMS Descriptor element is received indicating that there are no further buffered group addressed BUs for which the STA has previously received an FMS Response element in a frame that has an Address 1 value that matches its MAC address or that has an Address 1 value that is a group address corresponding to a group of which it is a member and that was transmitted by the AP with which it is associated and which had an Element Status value in the FMS Status subelement of “Accept”. See also 10.3.6.
- c) When the STA detects that the bit corresponding to its AID is 1 in the DTIM at the start of the CFP (or in a subsequent TIM during the CFP), the STA shall remain in the awake state for at least that portion of the CFP through the time that the STA receives an individually addressed BU from the AP carried in a frame with the More Data subfield in the Frame Control field indicating that no further traffic is buffered.
- d) If the More Data subfield in the Frame Control field of the last MPDU containing all or part of the BU received from the AP indicates that more traffic for the STA is buffered, then, when the CFP ends, the STA may remain in the awake state and transmit PS-Poll frames during the CP to request the delivery of additional buffered BUs, or may enter the doze state during the CP (except at TBTTs for DTIMs expected during the CP), awaiting the start of the next CFP.

11.2.3.10 Receive operation using APSD

A STA using APSD shall operate as follows to receive a BU from the AP:

- a) If a scheduled SP has been set up, the STA wakes up at its scheduled start time. (The STA shall wake up early enough to receive transmissions at the scheduled SP.)
- b) If the STA is initiating an unscheduled SP, the STA wakes up and transmits a trigger frame to the AP. When one or more ACs are not delivery-enabled, the STA may retrieve BUs using those ACs by sending PS-Poll frames to the AP.

- c) The STA shall remain awake until it receives a QoS Data frame or QoS Null frame addressed to it, with the EOSP subfield equal to 1.
- d) The STA may send additional PS-Poll frames if the More Data subfield is 1 in a downlink individually addressed MPDU containing all or part of a BU that does not use a delivery-enabled AC. The STA may send additional trigger frames if the More Data subfield is 1 in a downlink individually addressed MPDU containing all or part of a BU that uses a delivery-enabled AC.

For receive operation using the U-APSD coexistence mechanism, see additional procedures in 11.2.3.5.2.

11.2.3.11 STAs operating in the active mode

A STA operating in this mode shall have its receiver activated continuously; such STAs do not need to interpret the TIM elements in Beacon frames.

11.2.3.12 AP aging function

Any AP aging function shall not cause the buffered BU to be discarded after any period that is shorter than that indicated by the STA for which the BUs are buffered, in the Listen Interval field of its (Re)Association Request frame. The exact specification of the aging function is beyond the scope of this standard.

NOTE—This aging function is independent of (i.e., in addition to) other causes of MSDU discard within the MAC, such as due to the operation of a per-TS MSDU lifetime, or related to dot11QAPEDCABeaconLifetime.

11.2.3.13 PSMP power management

An AP transmits a PSMP frame containing a schedule only for STAs that are awake.

A STA with an established PSMP session (see 11.4.6) shall be awake at the start of the session's SP and shall remain awake until the end of the SP unless permitted to return to sleep as described in this subclause.

NOTE—A STA in power save mode can also be determined to be awake following receipt of a trigger frame according to the operation of the U-APSD protocol (as defined in 11.2.3.5), following receipt of a PS-Poll frame (as defined in 11.2.3.8), or following a DTIM Beacon (as defined in 11.2.3.8).

The AP may signal the end of the SP for all awake associated PSMP-capable STAs by setting the More PSMP field to 0 or by sending CF-End frame instead of the next PSMP frame.

NOTE 1—The AP can also signal the end of an SP on a per-STA basis using the EOSP subfield set to 1 in the QoS Control field, as defined in 9.2.4.5.3 and 11.2.3.6. This field remains set to 1 for any retransmissions of the same frame, and no more new frames are sent to this particular STA in the current SP.

NOTE 2—if a STA is awake at the start of a scheduled PSMP session, the operation of the More Data subfield in the Frame Control field and the TIM element are defined by the S-APSD rules in 11.2.3.5, 11.2.3.6, and 11.2.3.10.

A STA shall wake up at the start of the next PSMP frame if the More PSMP field is equal to 1 in the current PSMP frame, unless the STA has been permitted to return to sleep through the reception of a frame addressed to it with the EOSP subfield equal to 1 or the maximum SP interval has elapsed.

Within a PSMP sequence, a PPDU containing MPDUs addressed to a STA shall not start after the expiration of the STA's PSMP-DTT. A STA completes the reception of any PPDU that starts before the end of the PSMP-DTT. If no frames addressed to a STA begin within a PSMP-DTT, it can assume that no frame addressed to it will arrive during this PSMP sequence.

The STA shall be awake to receive at the start of the PSMP-DTT determined from a STA_INFO field that has the STA_INFO Type subfield equal to 2 and the AID field matching the STA's AID where the PSMP-DTT Duration subfield is not equal to 0.

11.2.3.14 TDLS peer power save mode

TDLS peer power save mode (TDLS peer PSM) is a power save mechanism that can be used between TDLS peer STAs, and which is based on a periodic wakeup schedule. A STA supports TDLS peer PSM if dot11TDLSPeerPSMActivated is true. A STA supporting this capability may indicate support through any TDLS Setup Request frame or TDLS Setup Response frame. A STA indicating this support shall signal this by setting the TDLS Peer PSM Support subfield in the Extended Capabilities element included in the TDLS Setup Request frame or TDLS Setup Response frame to 1. A station that signals support for this capability is capable of acting in both the TDLS peer PSM initiator and the TDLS peer PSM responder role.

A STA that intends to enter TDLS peer PSM (TDLS peer PSM initiator) shall send a TDLS Peer PSM Request frame to the TDLS peer STA (TDLS peer PSM responder), including a proposed periodic Wakeup Schedule. A TDLS Peer PSM Request frame shall not be transmitted to a STA that did not indicate support for TDLS peer PSM. When the TDLS peer PSM responder accepts the proposed Wakeup Schedule, it shall respond with a TDLS Peer PSM Response frame indicating status code SUCCESS. Otherwise, the TDLS peer PSM responder shall respond with a TDLS Peer PSM Response frame indicating the appropriate status code for rejecting the schedule. An alternative schedule shall be included in the TDLS Peer PSM Response frame when the status code is equal to TDLS_REJECTED_ALTERNATIVE_PROVIDED. The alternative schedule may be used by the TDLS peer PSM initiator to generate a new TDLS Peer PSM Request frame. After successfully transmitting or receiving a TDLS Peer PSM Response frame indicating status code SUCCESS, the TDLS peer PSM initiator and TDLS peer PSM responder have established a periodic wakeup schedule between them. The wakeup schedule remains valid until one of the following occurs:

- The TDLS direct link is torn down;
- The STAs explicitly update the existing wakeup schedule; or
- No MPDUs containing data have been exchanged for Idle Count consecutive Awake Windows.

A STA transmitting a TDLS Peer PSM Request frame shall remain in the awake state until it received the corresponding TDLS Peer PSM Response frame. A TDLS Peer PSM Request frame may be transmitted via the AP path or via the direct path (which is up to the implementer to decide). A TDLS Peer PSM Response frame shall be transmitted over the direct path.

The timing of the periodic schedule of the TDLS Peer PSM Awake Windows is based on the Offset field, the Interval field, the Awake Window Slots field, and the Maximum Awake Window Duration field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link.

Awake Windows begin at TSF values that satisfy the equation $\text{TSF mod Interval} = \text{Offset}$. The interval between the start of two successive Awake Windows is equal to the time in microseconds of the Interval field. The periodic wakeup schedule may be unrelated to the target beacon transmission time (TBTT) or the beacon interval.

Awake Windows end when the Awake Window Slot Counter reaches 0 or when the Maximum Awake Window Duration has been reached, whichever comes first.

The Awake Window Slot Counter counts down backoff slots that are determined using AIFS[AC_BE] in the same manner that normal backoff slots are determined according to 10.22.2.4.

The initial value of the Awake Window Slot Counter at the start of the Awake Window shall be equal to the value in the Awake Window Slots field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link.

The Awake Window Slot Counter begins counting at the beginning of the Awake Window and stops counting when it reaches 0.

A value of 0 in the Maximum Awake Window Duration field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link means that the end of the Awake Window duration is determined only by the Awake Window Slot Counter.

A value of 0 in the Awake Window Slots field of the Wakeup Schedule element that is contained in the TDLS Peer PSM Request frame that established TDLS peer PSM operation on the link means that the duration of the Awake Window is determined only by the Maximum Awake Window Duration.

The Maximum Awake Window Duration field and the Awake Window Slots field shall not both be set to 0 in a TDLS Peer PSM Request frame.

The Awake Window Slots field in a TDLS Peer PSM Request frame should be set to a value that is larger than CWmin[AC_BE].

A TDLS peer PSM service period is a period of time during which one or more individually addressed frames are transmitted between two TDLS peer STAs when at least one STA employs TDLS peer PSM. A TDLS peer PSM service period may be initiated during an Awake Window. A TDLS peer STA in power save mode may enter a doze state when it has successfully transmitted to and received from the corresponding TDLS peer STA in power save mode a QoS frame with the EOSP subfield equal to 1, ending the TDLS peer PSM service period. A TDLS peer STA in power save mode may enter a doze state when it has successfully received from the corresponding TDLS peer STA in active mode a QoS frame with the EOSP subfield equal to 1.

Either STA may update an existing schedule by initiating a TDLS Peer PSM Request/Response exchange. If the TDLS Peer PSM Response frame indicates status code SUCCESS, a new wakeup schedule is established for the TDLS direct link. Otherwise, the existing schedule still applies. The new schedule takes effect after the termination of the current TDLS peer PSM service period.

After the successful PSM setup, a STA informs its TDLS peer STA that it will enter power save mode per direct link by setting the Power Management subfield to 1 in an MPDU requiring acknowledgment. The STA enters power save mode after successful transmission of the MPDU. The power save status on one direct link is independent of the power save status on other links (direct or with the AP) the STA may have.

If a TDLS peer STA enters power save mode when a Wakeup Schedule is active, it shall be awake at the beginning of each scheduled periodic Awake Window, and stay awake for the duration of the Awake Window or until the end of a TDLS peer PSM service period. Otherwise, it may enter a doze state, depending on the current requirements to be awake, imposed by other links. A TDLS peer STA that did not enter power save mode shall remain in the awake state.

When both TDLS peer STAs set the More Data Ack subfield in their QoS Capability element to 1, then the More Data subfield inside an Ack frame set to 0 shall have the same function as the EOSP subfield inside a QoS frame set to 1. Transmission of an Ack frame with the More Data subfield set to 0 under these conditions is equivalent to a successful transmission of a QoS frame with the EOSP subfield set to 1.

When waking up at the beginning of an Awake Window, if a STA has no buffered BU to send to a TDLS Peer STA that had the More Data Ack subfield in its QoS Capability element equal to 1 during the TDLS setup exchange, the TDLS STA may send a QoS Null frame with the EOSP subfield of the QoS Control field set to 1, and the More Data subfield of the Frame Control field set to 0. If the TDLS peer STA that is the recipient of this QoS Null frame also has no buffered BU to deliver either, and it had the More Data Ack subfield in its QoS Capability element equal to 1 during the TDLS setup exchange, then the TDLS peer STA shall respond with an Ack frame that has the More Data subfield set to 0. The STA may discard the QoS Null frame if it has not been successfully transmitted at the end of the Awake Window. Before the successful transmission of the QoS Null frame, if a Data or QoS Null frame with an EOSP subfield equal to

1 is received from the TDLS peer STA the STA may cancel the pending transmission of the QoS Null frame after the transmission of an Ack frame with the More Data subfield set to 0.

To keep track of the connectivity over the direct link and to maintain the wakeup schedule, a TDLS peer STA may start an acknowledged frame exchange at least once per Idle Count consecutive Awake Windows, as a keepalive. For instance a QoS Null frame may be used as a keepalive frame. When a TDLS Peer PSM Response frame was successfully transmitted or received and no subsequent TDLS peer PSM service period has started for Idle Count consecutive wakeup periods, a TDLS peer STA shall delete the wakeup schedule for this link, which means that the related periodic wakeup no longer occurs (i.e., the TDLS peer STA no longer has to wake up during this period) and that a wakeup schedule no longer exists for this link. When traffic arrives at a TDLS peer STA in TDLS peer PSM mode for a link with no existing wakeup schedule, the STA shall send a TDLS Peer PSM Request frame through the AP path to the TDLS peer STA to activate a new wakeup schedule. When both TDLS peer STAs enter active mode while a wakeup schedule is active, no more TDLS peer PSM service periods will occur, causing the wakeup schedule to be deleted.

If a TDLS peer STA does not receive an acknowledgment to an individually addressed QoS frame sent with the EOSP subfield equal to 1 that terminates a TDLS peer PSM service period, it shall retransmit that frame at least once within the same service period, subject to the applicable retry or lifetime limit. The maximum number of retransmissions within the same service period is the lesser of the maximum retry limit and dot11TDLSPeerSTAMissingAckRetryLimit. If an acknowledgment to the retransmission of this last frame in the same service period is not received, the TDLS peer STA may wait until the next Awake Window to further retransmit that frame, subject to its applicable retry or lifetime limit. When the TDLS peer STA has transmitted an individually addressed frame that terminates a TDLS peer PSM service period then, except for retransmissions of that frame, the TDLS peer STA shall not transmit any more frames to the TDLS peer STA until the next Awake Window.

A TDLS peer STA that has an active Wakeup Schedule shall not decrement a backoff count outside the Awake Windows, if that backoff precedes a frame that is destined for transmission on the related TDLS direct link.

At the start of an Awake Window, the backoff procedure shall be invoked at an EDCAF if there is a frame available for transmission at that EDCAF, and the backoff timer for that EDCAF has been 0 for at least one backoff slot.

Outside of its Awake Windows, and during Awake Windows when on the base channel, a TDLS peer STA can engage in communications with the AP.

11.2.3.15 TDLS peer U-APSD (TPU)

11.2.3.15.1 General

A STA supports the TPU buffer STA function if dot11TDLSPeerUAPSDBufferSTAActivated is true. A non-QoS STA shall set dot11TDLSPeerUAPSDBufferSTAActivated to false. A STA supporting this capability may indicate support through any TDLS Setup Request frame or TDLS Setup Response frame. A STA indicates support by setting the TPU Buffer STA Support subfield in the Extended Capabilities element included in the TDLS Setup Request frame or TDLS Setup Response frame to 1. Support for the TPU buffer STA function means that the STA has the capability to buffer BUs destined to the TPU sleep STA, and to deliver them during unscheduled service periods.

To operate as the TPU sleep STA in TPU, a STA shall configure its TPU capable TDLS peer STA by setting one or more U-APSD Flag subfields inside the QoS Info subfield of the QoS Capability element carried in a TDLS Setup Response frame to 1, or by setting one or more U-APSD Flag subfields inside the QoS Info subfield of the EDCA Parameter Set element carried in a TDLS Setup Confirm frame to 1.

A STA that configured TPU at a TDLS peer STA enters power save mode on a TDLS direct link after the successful transmission to the TDLS peer STA over the direct link of an acknowledged MPDU with the Power Management subfield equal to 1. The STA that transmitted the frame with the Power Management subfield equal to 1 is then referred to as a *TPU sleep STA*. The STA that received the frame with the Power Management subfield equal to 1 is referred to as a *TPU buffer STA*. A TPU sleep STA may be a TPU buffer STA at the same time and on the same link, by sending a frame to the TDLS peer STA with the Power Management subfield of the Frame Control field set to 1 (this transmission will be preceded by the transmission of a Peer Traffic Indication frame and the subsequent receipt of a trigger frame that starts a service period). The power save status on one direct link is independent of the power save status on other links (direct or with the AP) the STA may have.

The procedure to trigger and terminate an unscheduled SP between TPU buffer STA and a TPU sleep STA are described in 11.2.3.5 and 11.2.3.6, where the TPU buffer STA shall take the role of the AP and the TPU sleep STA shall take the role of the non-AP STA using U-APSD, except that a frame with the EOSP subfield equal to 1 shall not act as a trigger frame.

11.2.3.15.2 TPU at the TPU buffer STA

BUs at a TPU buffer STA destined for a TPU sleep STA shall be temporarily buffered at the TPU buffer STA. The algorithm to manage this buffering is beyond the scope of this standard, except that the TPU buffer STA shall preserve the order of buffered BUs on a per-TID, per-STA basis.

A TPU buffer STA shall transmit an individually addressed TDLS Peer Traffic Indication frame to a TPU sleep STA, through the AP, if and only if all of the following conditions are met:

- A BU destined for a TPU sleep STA was placed into a buffer at the TPU buffer STA;
- The buffer into which the BU was placed contained no other frames with the same RA; and
- One or more periods of dot11TDLSPeerUAPSDIndicationWindow beacon intervals have expired after the last service period.

The TDLS Peer Traffic Indication frame shall be transmitted through the AP path.

The transmitted TDLS Peer Traffic Indication frame shall indicate the nonempty AC(s), by setting the corresponding AC Traffic Available subfield of the TDLS Peer Traffic Indication frame to 1.

A PTI Control element may be included in the TDLS Peer Traffic Indication frame, to allow the TPU sleep STA to not start a service period when the indicated traffic has already been received by the TPU sleep STA.

The TID field contained in the PTI Control element (if included) shall be set to the TID of the latest MPDU that has been transmitted over the TDLS direct link to the TPU sleep STA that is the destination of the TDLS Peer Traffic Indication frame that contains the PTI Control element.

The Sequence Control field contained in the PTI Control element (if included) shall be set to the sequence number of the latest MPDU that has been transmitted over the TDLS direct link to the TPU sleep STA that is the destination of the TDLS Peer Traffic Indication frame that contains the PTI Control element.

After transmitting a TDLS Peer Traffic Indication frame without a PTI Control element, the TPU buffer STA shall stay awake at least until the corresponding or a subsequent TDLS Peer Traffic Response frame is received.

After transmitting a TDLS Peer Traffic Indication frame without a PTI Control element, the TPU buffer STA shall stay awake at least until the MPDU following the MPDU indicated in the Sequence Control field of the PTI Control element is successfully transmitted.

When no corresponding TDLS Peer Traffic Response frame has been received within dot11TDLSResponseTimeout after sending a TDLS Peer Traffic Indication frame, the STA shall tear down the direct link.

11.2.3.15.3 TPU at the TPU sleep STA

When a TPU sleep STA receives a TDLS Peer Traffic Indication frame without a PTI Control element, the TPU sleep STA shall initiate a service period with the TPU buffer STA during which it shall transmit at least a TDLS Peer Traffic Response frame. The TDLS Peer Traffic Response frame shall echo the values of the Dialog Token and Link Identifier fields from the corresponding TDLS Peer Traffic Indication frame. The TDLS Peer Traffic Response frame shall be sent via the direct path.

When a TPU sleep STA receives a TDLS Peer Traffic Indication frame with a PTI Control element, and the TPU sleep STA has not received from the TPU buffer STA the MPDU following the MPDU that is indicated in the TDLS Peer Traffic Indication frame, the TPU sleep STA shall initiate a service period with the TPU buffer STA to retrieve the buffered traffic for the AC(s) for which no unscheduled SP is currently active.

11.2.3.16 FMS power management

11.2.3.16.1 General

Implementation of FMS is optional for a WNM STA. A STA whose dot11FMSActivated is true shall support FMS and shall set to 1 the FMS field of the Extended Capabilities elements that it transmits.

11.2.3.16.2 FMS general procedures

When dot11FMSActivated is true at the AP, the AP shall include the FMS Descriptor element in every Beacon frame. The FMS Descriptor indicates the FMS group addressed buffered BUs at the AP. If there are no buffered BUs for FMS streams accepted by the AP, the AP shall set the Length field in the FMS Descriptor element to 1. The AP shall include the FMS Descriptor element for a nontransmitted BSSID in the Multiple BSSID element sent in a Beacon frame.

When dot11FMSActivated is true at the AP, the AP shall support from one to eight different FMS Stream delivery intervals for any number of FMS streams. Corresponding to these eight delivery intervals are eight FMS counters. More than one FMSID may have the same delivery interval and therefore will share the same FMS Counter. An FMS Counter corresponds to each unique delivery interval of one or more FMS Streams.

Each FMS counter decrements once per DTIM beacon and when the FMS counter reaches 0, buffered group addressed BUs assigned to that particular interval are scheduled for delivery immediately following the next Beacon frame containing the DTIM transmission. After transmission of the buffered group addressed BUs, the AP shall reset the FMS counter to the delivery interval for the FMS streams associated with that FMS counter.

A non-AP STA that does not use FMS wakes every DTIM interval and follows group addressed BU reception rules as defined in 11.2.3.8.

A STA that supports FMS shall be capable of supporting a delivery interval of 1 for any stream.

11.2.3.16.3 FMS Request procedures

A non-AP STA that supports FMS may request use of FMS by sending an FMS Request frame or Reassociation Request frame that includes one or more FMS Request elements to an AP that supports FMS. Each FMS Request element includes one or more FMS subelements. Each FMS subelement identifies an

FMS stream, the requested delivery interval and the maximum delivery interval for that stream. The FMS delivery interval shall be an integer multiple of the DTIM period.

Upon reception of an FMS Request frame or Reassociation Request frame, the AP shall transmit a corresponding single FMS Response frame or Reassociation Response frame that contains a corresponding FMS Response element for each FMS Request element in the same order received. Each FMS Response element shall contain an FMS Status subelement and zero or more other subelements drawn from Table 9-197 that corresponds to each FMS subelement in the FMS Request element, in the same order.

For each FMS subelement, the following rules apply:

If the AP accepts the FMS subelement and the requested delivery interval, the Element Status in the corresponding FMS Status subelement shall be set to “Accept” and the FMSID is assigned to a nonzero value. In addition:

- If the FMS stream identified in the FMS subelement matches a delivery interval already in use at the AP, the AP shall assign the FMS stream to use the FMS Counter ID assigned for that delivery interval.
- When an FMS Stream is accepted by the AP, the Current Count value for that FMS Stream is decremented by 1 for each DTIM Beacon frame in which the Current Count field appears.
- The AP may reschedule transmission of the FMS Stream identified by an FMSID to align the transmission time of the FMS stream to the transmission time of other FMS streams that the STA is already receiving at the same delivery interval. The AP has the following two options:
 - Notify the STAs using that FMS Stream. The AP shall keep the nonzero Current Count value the same across two consecutive Beacon frames in which the Current Count field appears. The algorithm by which the AP chooses to align or offset the different FMS counters is unspecified.
 - Transmit an unsolicited FMS Response frame to the group address included in the original FMS Response frame for the stream with the updated Delivery Interval field when the Current Count field value reaches 0. Since the AP transmits this FMS Response frame as a group addressed frame, the frame will be scheduled for delivery at the appropriate DTIM interval when all non-AP STAs are awake to receive the frame.
- An AP may terminate the use of FMS and resume default (non-FMS) transmission rules for any FMS stream identified by FMSID for any reason. To terminate the FMS stream, the AP shall send an unsolicited FMS Response frame to the group address included in the original FMS Response frame with Delivery Interval set to 0 and the Element Status in the FMS Status subelement set to one of “Terminate, due to AP policy change”, “Terminate, due to lack of resources of AP,” and “Terminate, due to other FMS stream with higher priority”.
- If the FMS subelement contained a nonzero delivery interval and the non-AP STA specified a maximum delivery interval as part of the FMS request, the AP shall not modify the delivery interval for the stream greater than the maximum delivery interval specified by the non-AP STA.
- An AP shall transmit MSDUs belonging to the same FMSID in the same order that they were received at the MAC Data SAP. MSDUs belonging to the different FMSIDs are transmitted by the AP at the appropriate DTIM in the order received at the MAC data SAP based on the interval configured for the FMS stream.

If the AP denies the FMS subelement for any reason, including requested delivery interval, maximum delivery interval and TCLAS, the Element Status in the corresponding FMS Status subelement shall be set to one of “Deny, due to request format error or ambiguous classifier”, “Deny, due to lack of resources on AP”, “Deny, due to requested classifier(s) matching 2 or more existing streams on different intervals,” “Deny, by policy, requested stream or filter is not permitted to participate in the service”, and “Deny, reason unspecified”.

If the AP selects an alternate delivery interval or alternate maximum delivery interval from the value specified in the FMS Request, the Element Status field in the corresponding FMS Status subelement shall be set to one of “Alternate proposed, due to existing stream with different delivery interval”, “Alternate proposed, due to policy limits on AP”, “Alternate proposed, because the AP changed the delivery interval”, and “Alternate proposed, because the AP changed the maximum delivery interval” and the FMS subelement shall indicate the AP selected value(s).

To terminate the use of FMS for an FMS Stream identified by FMSID, the non-AP STA shall transmit an FMS Request frame with an FMS Request element and FMS subelement with the FMSID matching the FMS stream and the delivery interval set to 0.

The AP shall respond to a malformed FMS Request frame or Reassociation Request frame with an FMS Response frame or Reassociation Response frame that denies all FMS Request elements by including an FMS Status code “Deny, due to request format error or ambiguous classifier” in the Element Status field in each FMS Status subelement in the FMS Response element.

11.2.3.16.4 FMS Response procedures

Upon reception of an FMS Response element in a frame that has a value in Address 1 that matches its MAC address or that is a group address corresponding to a group of which it is a member and that was transmitted by the AP with which it is associated, a non-AP STA that supports FMS shall use the following procedures, based on the value of the Element Status value in the FMS Status subelement in the received FMS Response element.

- If the Element Status value in the FMS Status subelement is “Accept”:
 - The AP has accepted the FMS subelement contained within the FMS Request element. If the FMS Request element specified a nonzero delivery interval, the AP will deliver the requested streams at the delivery interval as specified by the non-AP STA in the FMS Request element.
 - After receiving the FMS Response element, the non-AP STA shall be awake for the next DTIM beacon so that the non-AP STA can synchronize with the FMS Current Count for the requested FMS Stream. Once synchronized with the FMS Current Count, the non-AP STA need not wake up at every DTIM interval to receive group addressed BUs.
- If the Element Status value in the FMS Status subelement is one of “Deny, due to request format error or ambiguous classifier”, “Deny, due to lack of resources on AP”, “Deny, due to requested classifier(s) matching 2 or more existing streams on different intervals”, “Deny, by policy, requested stream or filter is not permitted to participate in the service”, and “Deny, reason unspecified”:
 - The AP does not deliver the requested streams at the delivery interval as specified by the non-AP STA in the FMS Request element. The AP delivers the requested stream at every DTIM interval.
- If the Element Status value in the FMS Status subelement is one of “Alternate proposed, due to existing stream with different delivery interval”, “Alternate proposed, due to policy limits on AP”, “Alternate proposed, because the AP changed the delivery interval”, and “Alternate proposed, because the AP changed the maximum delivery interval”:
 - The AP does not deliver the requested streams at the delivery interval and maximum delivery interval as specified by the non-AP STA in the FMS Request element. The FMS Status subelement specifies a delivery interval and a maximum delivery interval that the AP is willing to accept for the specified streams if the non-AP STA sends another FMS Request with that delivery interval and maximum delivery interval specified.
 - The non-AP STA may submit a new FMS Request that includes the delivery interval value received from the AP. If the AP accepts this new FMS Request, it shall respond as described in 11.2.3.16.2.

- If the Element Status value in the FMS Status subelement is “Alternate proposed, because the AP is unable to provide requested TCLAS-based classifiers”:
 - The AP does not deliver the requested streams at the delivery interval as specified by the non-AP STA in the FMS Request element. The TCLAS element(s) or TCLAS Processing element in the TCLAS Status subelement contains one or more fields or subfields whose values have been modified by the AP. The AP may include fewer TCLAS elements in the FMS Response element than were present in the request; when the AP’s response includes a single TCLAS element, it does not include a TCLAS Processing element. If the AP changes a TCLAS element’s Classifier Type field in the FMS Response element but is unable to suggest a value for the Classifier Mask field, it shall set that field to 0. If the AP changes a TCLAS element’s Classifier Type field or Classifier Mask field in the FMS Response element but is unable to suggest values for one or more Classifier Parameter subfields, it shall set those fields to 0.
 - A non-AP STA receiving a modified TCLAS element having a Classifier Mask field equal to 0 or Classifier Parameter subfields equal to 0 shall interpret these values as meaning that no suggested value has been provided by the AP.
- If the Element Status value in the FMS Status subelement is one of “Terminate, due to AP policy change”, “Terminate, due to lack of resources of AP”, and “Terminate, due to other FMS stream with higher priority”:
 - The AP will terminate the use of FMS transmission rules for any FMS stream identified by FMSID. If the AP terminates the usage of FMS for a particular stream, the stream is transmitted at DTIM interval.
 - The non-AP STA shall wake up at every DTIM interval to receive group addressed BUs after receiving the FMS Response element.

11.2.3.17 TIM Broadcast

Implementation of TIM Broadcast is optional for a WNM STA. A STA that implements TIM Broadcast has `dot11TIMBroadcastImplemented` equal to true. When `dot11TIMBroadcastImplemented` is true, `dot11WirelessManagementImplemented` shall be true. A STA whose `dot11TIMBroadcastActivated` value is true shall support TIM Broadcast and shall set to 1 the TIM Broadcast field of the Extended Capabilities elements that it transmits. This subclause describes TIM broadcast procedures for STAs whose `dot11TIMBroadcastActivated` is true.

TIM frames have shorter duration than Beacon frames and are potentially transmitted at a higher data rate. TIM Broadcast allows a non-AP STA to receive a TIM element without receiving a Beacon frame that may reduce the required wake time in a power save mode. The shorter receive time reduces the power consumption for non-AP STAs in a power save mode. The shorter receive time may reduce the power consumption for stations in a standby mode.

A non-AP STA may activate the TIM broadcast service by including a TIM Broadcast Request element in a TIM Broadcast Request frame, Association Request frame or Reassociation Request frame that is transmitted to the AP, which specifies the requested interval between TIM frame transmissions (the TIM broadcast interval). On receipt of a properly formatted TIM Broadcast Request element in a TIM Broadcast Request frame, Association Request frame or Reassociation Request frame, the AP shall include a TIM Broadcast Response element in the corresponding TIM Broadcast Response frame, Association Response frame or Reassociation Response frame, when `dot11TIMBroadcastActivated` is true. When the requested TIM broadcast interval is acceptable, the AP shall include a TIM Broadcast Response element specifying the requested TIM broadcast interval and a Status field indicating “Accept” when no valid TSF timestamp is present in the TIM frames, or “Accept, valid timestamp present in TIM frames” when a valid TSF timestamp is present in the TIM frames. When the AP overrides the requested TIM broadcast interval, it shall include a TIM Broadcast Response element specifying a different TIM broadcast interval and a Status field indicating “Overridden” when no valid TSF timestamp is present in the TIM frames, or “Overridden, valid timestamp present in TIM frames” when a valid TSF timestamp is present in the TIM frames, and include in the TIM

Broadcast Response element the smallest TIM broadcast interval that is currently active. Otherwise, the AP shall include a TIM Broadcast Response element with a Status field indicating “Denied.” The Status field in a TIM Broadcast Response element that is included in an Association Response frame or Reassociation Response frame has implications only for the TIM Broadcast negotiation.

NOTE—The STA might ignore the TIM Broadcast Interval field in the TIM Broadcast Response element if the Status field indicates “Accept” or “Accept, valid timestamp present in TIM frames”, because the TIM broadcast interval is the requested one.

An AP transmitting a TIM frame with a valid TSF timestamp shall set the value of the TIM frame timestamp as defined in 11.1.3, for the Beacon frame timestamp.

If the AP accepted at least one TIM Broadcast Request with a nonzero TIM Broadcast Interval field, and at least one non-AP STA in PS mode still associated with the AP received in its latest TIM Broadcast Response a status field value equal to 0 (Accepted) in response to a TIM Broadcast Request with a nonzero TIM Broadcast Interval field, the AP shall transmit one or two TIM frames per TIM Broadcast Interval. The AP shall not transmit TIM frames otherwise. When TIM broadcast intervals overlap, a transmitted TIM frame serves both intervals and does not need to be duplicated.

If the AP transmits two TIM frames per TIM Broadcast Interval, the AP shall transmit the high data rate TIM frame first, followed by the low data rate TIM frame.

The AP shall transmit the low data rate TIM frame at the same data rate or MCS as the Beacon frame. The AP shall transmit the high data rate TIM frame at a higher data rate or using an MCS that corresponds to a higher data rate. For Clause 18 and Clause 19 PHYs, if the Beacon frame is transmitted using ERP-DSSS/CCK, the AP shall transmit the high data rate TIM frame and shall transmit it using ERP-OFDM. Otherwise, transmitting the high data rate TIM frame is optional. If the high data rate TIM is not transmitted, the AP shall set the High Data Rate TIM field to 0 in the TIM Broadcast Response element.

The value of the TIM Broadcast Interval field from the latest received TIM Broadcast Response element (N_{TBI}) together with dot11BeaconPeriod define a series of target TIM transmission times (TTTTs) $N_{TBI} \times \text{dot11BeaconPeriod}$ TUs apart. Time 0 is a TTTT. A non-AP STA may use the information in the High Rate TIM Rate and Low Rate TIM Rate fields to determine which of the two TIM frames they will be receiving. The first TIM frame per TIM broadcast interval is scheduled to be transmitted at the TTTT plus the indicated TIM broadcast offset. The offset may have a negative value that allows the TIM frame(s) to be transmitted before the TBTT. The value of the offset shall not be changed as long as an associated non-AP STA is using the TIM broadcast service.

The AP should accept new TIM broadcast interval requests if this implies transmitting TIM frames more frequently. For instance, if the AP currently transmits TIM frames every fourth beacon period and it receives a new request for every 3 beacon periods, then the AP should accept the new request and transmit TIM frames both every 3 and every 4 beacon periods. The AP may override incongruent requests once available resources (such as counters) have been depleted. An incongruent request is a request that contains an interval that is not an integer divide or a multiple of a currently active TIM Broadcast interval.

The AP shall accept a TIM broadcast interval of 1.

NOTE—The DTIM Period subfield in a TIM element in a TIM frame indicates the period for DTIM Beacon frames and is unrelated to any TIM Broadcast Interval(s).

The AP shall increase the value (modulo 256) of the Check Beacon field in the next transmitted TIM frame(s) when a critical update occurs to any of the elements inside the Beacon frame. The following events shall classify as a critical update:

- a) Inclusion of a Channel Switch Announcement element
- b) Inclusion of an Extended Channel Switch Announcement element

- c) Modification of the EDCA parameters element
- d) Inclusion of a Quiet element
- e) Modification of the DSSS Parameter Set
- f) Modification of the CF Parameter Set element
- g) Modification of the HT Operation element
- h) Inclusion of a Wide Bandwidth Channel Switch element
- i) Inclusion of a Channel Switch Wrapper element
- j) Inclusion of an Operating Mode Notification element
- k) Inclusion of a Quiet Channel element
- l) Modification of the VHT Operation element

An AP may classify other changes in the Beacon frame as critical updates.

The non-AP STA shall attempt to receive the next Beacon frame when it receives a Check Beacon field that contains a value that is different from the previously received Check Beacon field.

When dot11MultiBSSIDActivated is true, the bitmap of the TIM element is interpreted as specified in 9.4.2.6.

When dot11MultiBSSIDActivated is true, the A1 field of the TIM frame is the Broadcast address, the A2 field and the A3 field are set to the transmitted BSSID.

11.2.3.18 WNM sleep mode

11.2.3.18.1 WNM sleep mode capability

Implementation of the WNM sleep mode capability is optional for a WNM STA. A STA that implements WNM sleep mode has dot11WNMSleepModeImplemented equal to true. When dot11WNMSleepModeImplemented is true, dot11WirelessManagementImplemented shall be true. A STA where dot11WNMSleepModeActivated is true is defined as a STA that supports WNM sleep mode. A STA supporting WNM sleep mode shall set the WNM Sleep Mode field of the Extended Capabilities element to 1. When dot11WNMSleepModeActivated is true, dot11TFSActivated shall be true.

A STA in which dot11WNMSleepModeActivated is true may send a WNM Sleep Mode Request or WNM Sleep Mode Response frame to a STA within the same infrastructure BSS whose last received Extended Capabilities element contained a value of 1 for the WNM Sleep Mode field in the Extended Capabilities field. WNM sleep mode is a service that may be provided by an AP to its associated STAs. The WNM sleep mode is not supported in an IBSS.

WNM sleep mode enables an extended power save mode for non-AP STAs in which a non-AP STA need not listen for every DTIM Beacon frame, and need not perform GTK/IGTK updates. A non-AP STA can sleep for extended periods as indicated by the WNM Sleep Interval field of the WNM Sleep Mode element, which is present in WNM Sleep Mode Request frames transmitted by the non-AP STA.

11.2.3.18.2 WNM sleep mode non-AP STA operation

To use the WNM sleep mode service, the non-AP STA's SME shall issue an MLME-SLEEPMODE.request primitive to send a WNM Sleep Mode Request frame. The MLME-SLEEPMODE.request primitive shall include a valid SleepMode parameter with a WNM Sleep Mode element. The Action Type field in the WNM Sleep Mode element shall be set to “Enter WNM sleep mode” and the WNM Sleep Interval field shall be included. The WNM Sleep Interval field shall be less than the BSS max idle period (see 11.24.13). The

MLME-SLEEPMODE.request primitive shall also include a valid TFSRequest parameter as defined in the TFS Request element that the AP shall use as triggers to set the STA's TIM bit.

When a traffic filter for group addressed frames is enabled at the AP, the STA may request a notification frame (see 11.24.12.2) be sent when requesting the establishment of the traffic filtering agreement.

The receipt of an MLME-SLEEPMODE.confirm primitive with a valid SleepMode parameter indicates to the STA's SME that the AP has processed the corresponding WNM Sleep Mode Request frame. The content of the WNM sleep mode parameter in the WNM Sleep Mode Response frame provides the status of WNM Sleep Mode elements processed by the AP. The non-AP STA shall delete the GTKSA if the response indicates success. If RSN is used with management frame protection, the non-AP STA shall delete the IGTKSA if the response indicates success.

While in WNM sleep mode, the non-AP STA need not wake up every DTIM interval for group addressed frames.

The STA wakes up at intervals not longer than the value indicated by the WNM Sleep Interval field to check whether the corresponding TIM bit is set or group addressed traffic is pending. The non-AP STA does not participate in GTK/IGTK updates.

To exit WNM sleep mode, the non-AP STA's SME shall issue an MLME-SLEEPMODE.request primitive to send a WNM Sleep Mode Request frame with an Action Type field in the WNM Sleep Mode element set to "Exit WNM sleep mode". If a STA receives an unsolicited WNM Sleep Mode Response frame with the WNM Sleep Mode Response status value (see Table 9-204) equal to 1, the STA exits WNM sleep mode.

11.2.3.18.3 WNM sleep mode AP operation

When an AP's SME receives an MLME-SLEEPMODE.indication primitive with a valid SleepMode parameter and an Action Type in the WNM Sleep Mode element of "Enter WNM sleep mode" it shall issue an MLME-SLEEPMODE.response primitive with SleepMode parameters indicating the status of the request. The value of the Action Type field of the WNM Sleep Mode element in the WNM Sleep Mode Response frame shall be set to "Enter WNM sleep mode".

When WNM sleep mode is enabled for an associated STA, the AP shall stop sending all individually addressed MPDUs to the non-AP STA. The AP may disassociate or deauthenticate the STA at any time for any reason while the non-AP STA is in WNM sleep mode. An AP shall perform the TFS AP operation, as specified in 11.24.12 for non-AP STAs for which it has received TFS Request elements. The AP shall set the TIM bit corresponding to the AID of the associated STA for which the AP has queued either a TFS Notify frame or matching frame. An AP shall not perform GTK/IGTK updates for the STAs in WNM sleep mode.

When an AP's SME receives an MLME-SLEEPMODE.indication primitive with a valid SleepMode parameter and an Action Type in the WNM Sleep Mode element of "Exit WNM sleep mode" the AP shall disable WNM sleep mode service for the requesting STA, and the AP's SME shall issue an MLME-SLEEPMODE.response primitive with a SleepMode parameter indicating the status of the associated request. When all traffic filter sets established for a STA are deleted upon frame matches, the AP shall also disable the WNM sleep mode service and transmit to the STA an unsolicited WNM Sleep Mode Response frame with the WNM Sleep Mode Response status value (see Table 9-204) set to 1.

If RSN is used with management frame protection and a valid PTK is configured for the STA, the current GTK and IGTK shall be included in the WNM Sleep Mode Response frame. If a GTK/IGTK update is in progress, the pending GTK and IGTK shall be included in the WNM Sleep Mode Response frame. If RSN is used without management frame protection and a valid PTK is configured for the STA, the current GTK shall be sent to the STA using a group key handshake (see 12.7.7) immediately following the WNM Sleep Mode Response frame.

11.2.3.19 VHT TXOP power save

A VHT AP supports the operation of non-AP VHT STAs in TXOP power save mode in a BSS when the dot11VHTTXOPPowerSaveOptionImplemented at the AP is true. Non-AP VHT STAs that are in active mode and have dot11VHTTXOPPowerSaveOptionImplemented equal to true operate in TXOP power save mode. A STA that has dot11VHTTXOPPowerSaveOptionImplemented equal to true shall set the TXOP PS field in the VHT Capabilities element to 1; otherwise, the STA shall set the field to 0. A VHT AP may allow non-AP VHT STAs in TXOP power save mode to enter the doze state during a TXOP, which the AP does by transmitting a VHT PPDU with the TXVECTOR parameter TXOP_PS_NOT_ALLOWED set to 0. The value of this parameter in the TXVECTOR of all VHT PPDUs transmitted by the VHT AP may be changed from 1 to 0 during the TXOP to enable TXOP power save mode for the remainder of the TXOP. The value of this parameter in the TXVECTOR of all VHT PPDUs transmitted by VHT AP shall not be changed from 0 to 1 during the TXOP. If the dot11VHTTXOPPowerSaveOptionImplemented at VHT AP is false then the VHT AP shall set the TXOP_PS_NOT_ALLOWED to 1 in the TXVECTOR of the frames with FORMAT VHT.

If the AP allows non-AP VHT STAs to enter doze state during a TXOP, then a non-AP VHT STA that is in TXOP power save mode may enter the doze state until the end of that TXOP when one of the following conditions is met:

- On receipt of a VHT MU PPDU, the STA determines that it is not a member of the group indicated by the RXVECTOR parameter GROUP_ID.
- On receipt of an SU PPDU, the STA determines that the RXVECTOR parameter PARTIAL_AID is not equal to 0 nor does it match the STA's partial AID.
- The STA finds that the PARTIAL_AID in the RXVECTOR matches its partial AID but the RA in the MAC header of the corresponding frame that is received correctly does not match the MAC address of the STA.
- The STA receives a frame with an RXVECTOR parameter NUM_STS equal to 0 if it is a member of group indicated by RXVECTOR GROUP_ID.
- In a received VHT NDP Announcement frame, the STA finds that the RXVECTOR parameter PARTIAL_AID is 0 and the AID in the STA Info field is not its AID.
- The STA receives a frame intended for it with the More Data subfield equal to 0 and the Ack Policy subfield in the QoS Control field is equal to No Ack or sends an acknowledgment if Ack Policy subfield is not equal to No Ack.

The VHT AP shall include a nav-set sequence (e.g., RTS/CTS) (see G.4 at the beginning of such a TXOP with the Duration/ID value set to the remainder of the TXOP duration. A VHT AP shall not transmit frames to a non-AP VHT STA that has been allowed to enter doze state according to the conditions above for the remainder of the TXOP.

NOTE—A VHT AP does not transmit VHT SU PPDUs in the current TXOP if the AP has already transmitted a VHT PPDU with the TXVECTOR parameter TXOP_PS_NOT_ALLOWED set to 0 in the same TXOP and does not want the STAs that are in awake state to enter the doze state.

If a VHT AP truncates the TXOP in which it allowed STAs to enter doze state, then the VHT AP shall not transmit frames to the STAs that were allowed to enter the doze state until the NAV set at the start of the TXOP has expired.

Under all of the following conditions:

- an AP transmitted a PPDU;
- the PPDU contains individually addressed frame that contains all or part of an MSDU, A-MSDU or MMPDU;
- the frame is addressed to a non-AP VHT STA that is in TXOP power save mode;

- the value of the frame's More Data subfield is 0;
- the transmitted PPDU's TXVECTOR parameter TXOP_PS_NOT_ALLOWED is 0;
- the AP did not receive an acknowledgment to this transmission;

then the AP shall retransmit that frame one or more times within the same TXOP, subject to applicable transmission restrictions. These restrictions include retry and lifetime limits, the TXOP limit and the rules on TXOP sharing (see 10.22.2.6). If an acknowledgment to the retransmission of this last frame in the same TXOP is not received, it may wait until the next TXOP to further retransmit that frame, subject to its applicable retry or lifetime limit.

NOTE—An AP that receives from a VHT STA in TXOP power save mode a BlockAck frame that is a response to an A-MPDU containing MPDUs with the More Data subfield equal to 0 cannot expect to receive a response to subsequent MPDUs retransmitted in the same TXOP because the VHT STA might be in the doze state.

A VHT STA that is in TXOP power save mode and has entered doze state shall continue to operate its NAV during doze state and shall transition into awake state on the expiration of the NAV.

NOTE—The STA can contend for access to the medium immediately on the expiration of the NAV.

11.2.4 Power management in an IBSS

11.2.4.1 Introduction

Subclause 11.2.4 specifies the power management mechanism for use within an IBSS.

11.2.4.2 Basic approach

A STA can be in one of two power management modes:

- Active mode: The STA receives and transmits frames at any time. The STA remains in the awake state.
- Power save (PS) mode: The STA enters the awake state to receive or transmit frames. The STA remains in the doze state otherwise.

The basic approach is similar to the infrastructure case in that the STAs are synchronized, and group addressed BUs and the BUs that are to be transmitted to a power-conserving STA are first announced during a period when all STAs are awake. The announcement is done via an ATIM frame sent in an ATIM window. A STA in the PS mode shall listen for these announcements to determine if it needs to remain in the awake state. The presence of the ATIM window in the IBSS indicates if the STA may use PS mode. To maintain correct information on the power save state of other IBSS STAs, a STA needs to remain awake during the ATIM window. At other times the STA may enter the doze state except as indicated in the following procedures.

When a BU is to be transmitted to a destination STA that is in a PS mode, the transmitting STA first transmits an ATIM frame during the ATIM window, in which all of the STAs including those operating in a PS mode are awake. The ATIM window is defined as a specific period of time, defined by the value of the ATIM Window field in the IBSS Parameter Set supplied to the MLME-START.request primitive, following a TBTT, during which only Control frames that are RTS, CTS, or Ack frames; Management frames that are Beacon or ATIM frames; or (QoS) Null frames shall be transmitted. ATIM frame transmission times are randomized, after a Beacon frame is either transmitted or received by the STA, using the backoff procedure with the CW equal to aCWmin. Individually addressed ATIM frames shall be acknowledged. If a STA transmitting an individually addressed ATIM frame does not receive an acknowledgment, the STA shall execute the backoff procedure for retransmission of the ATIM frame. Group addressed ATIM frames shall not be acknowledged.

If a STA receives an individually addressed ATIM frame during the ATIM window, it shall acknowledge the individually addressed ATIM frame and stay awake to receive the announced BUs for the entire beacon interval or until it has completed successful transmission to and reception from the source STA of the received ATIM frame, a frame with the EOSP subfield equal to 1. If a STA does not receive an ATIM frame, it may enter the doze state at the end of the ATIM window. Transmissions of BUs announced by ATIM frames are randomized after the ATIM window, using the backoff procedure described in Clause 10.

It is possible that an ATIM frame may be received from more than one STA, and that a STA that receives an ATIM frame may receive more than a single BU from the transmitting STA. ATIM frames are only addressed to the destination STA of the BU.

An ATIM frame for a BU shall have a destination address identical to that of the BU.

After the ATIM interval, only individually addressed BUs that have been successfully announced with an acknowledged ATIM frame and group addressed BUs that have been announced with an ATIM frame shall be transmitted to STAs in the PS mode. These frames shall be transmitted using the DCF (for non-QoS STAs) or EDCAF (for QoS STAs).

Figure 11-8 illustrates the basic PS operation.

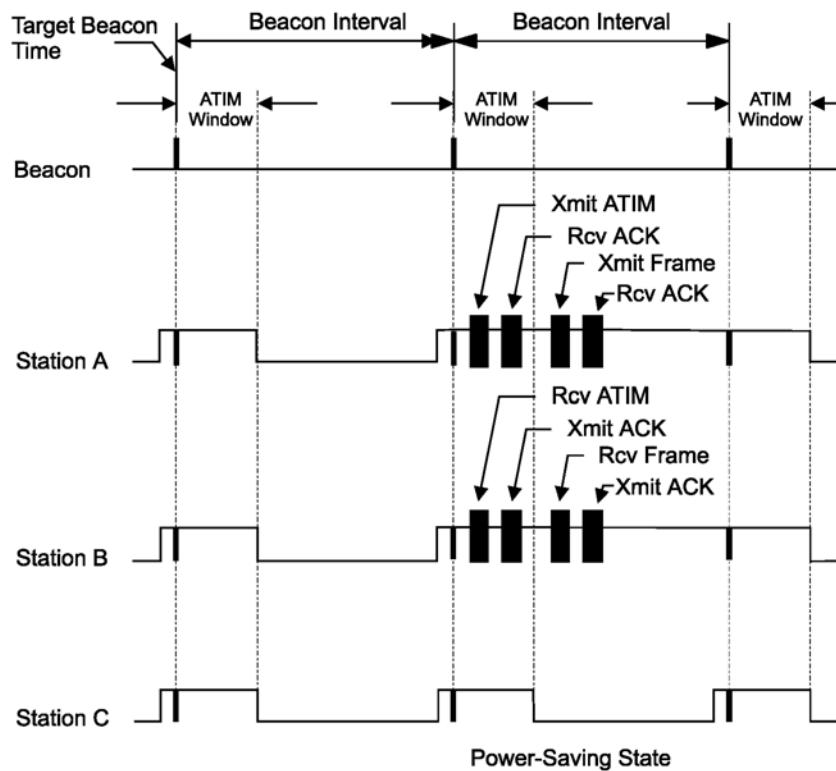

Figure 11-8—Power management in an IBSS—basic operation

The estimated power-saving state of another STA may be based on the power management information transmitted by that STA and on additional information available locally, such as a history of failed transmission attempts. The use of RTS/CTS in an IBSS may reduce the number of transmissions to a STA that is in PS mode. If an RTS frame is sent and a CTS frame is not received, the transmitting STA may assume that the destination STA is in PS mode. The method of estimating the power management state of other STAs in the IBSS is outside the scope of this standard.

11.2.4.3 Initialization of power management within an IBSS

The following procedure shall be used to initialize power management within a new IBSS, or to learn about the power management being used within an existing IBSS:

- a) A STA joining an existing IBSS by the procedure in 11.1.4.4 shall update its ATIM window with the value contained in the ATIM Window field of the IBSS Parameter Set element within the Beacon or Probe Response frame received during the scan procedure.
- b) A STA creating a new IBSS by the procedure in 11.1.4.4 shall set the value of the ATIM Window field of the IBSS Parameter Set element within the Beacon frames transmitted to the value of its ATIM window.
- c) The start of the ATIM window shall be the TBTT, defined in 11.1.3.5. The end of the ATIM window shall be defined as
 - TSF timer mod dot11BeaconPeriod = ATIMWindow,where ATIMWindow is the value of the ATIM Window field of the IBSS Parameter Set from the MLME-START.request or MLME-JOIN.request primitives.
- d) The ATIM window period shall be static during the lifetime of the IBSS.
- e) An ATIM window value of 0 shall indicate that power management is not usable within the IBSS.

11.2.4.4 STA power state transitions

A STA may enter PS mode if the value of the ATIM window in use within the IBSS is greater than 0. A STA shall not enter PS mode if the value of the ATIM window in use within the IBSS is equal to 0.

A STA shall indicate its power management mode in the Power Management subfield of the Frame Control field of frames containing all or part of a BU or individually addressed Probe Request frame, or (QoS) Null frames, that it transmits.

A STA in PS mode shall transition between awake state and doze state according to the following rules:

- a) If a STA is operating in PS mode, it shall enter the awake state prior to each TBTT.
- b) If a STA receives a group addressed ATIM frame during the ATIM window, the STA shall remain in the awake state until either the STA receives a group addressed frame from the source STA with the EOSP subfield equal to 1 or the end of the next ATIM window, whichever occurs first.
- c) If a STA receives at least one individually addressed ATIM frame containing the STA's individual address in the RA field during the ATIM window then the STA shall remain in the awake state at least until the earlier of the completion of the successful transmission to and reception from the source STA of each received ATIM frame, a frame with the EOSP subfield equal to 1, and the end of the next ATIM window.
- d) If a STA transmits at least one individually addressed ATIM frame containing a STA's individual address in the RA field during the ATIM window then the STA shall remain in the awake state at least until the earlier of the completion of the successful transmission to and reception from the destination STA of each transmitted ATIM frame, a frame with the EOSP subfield equal to 1, and the end of the next ATIM window.
- e) If a STA transmits a Beacon, the STA shall remain in the awake state until the end of the next ATIM window.
- f) If the STA has not transmitted an ATIM frame and does not receive either an individually addressed ATIM frame containing the STA's individual address, or a group addressed ATIM frame during the ATIM window, the STA may return to the doze state following the end of the current ATIM window.

11.2.5 Power management in an MBSS

Power management in an MBSS is described in 14.14.

11.2.6 SM power save

A STA consumes power on all active receive chains, even though they are not necessarily required for the actual frame exchange. The SM power save feature allows a non-AP HT STA in an infrastructure BSS to operate with only one active receive chain for a significant portion of time.

The STA controls which receive chains are active through the PHY-RXCONFIG.request primitive specifying a PHYCONFIG_VECTOR parameter ACTIVE_RXCHAIN_SET that indicates which of its receive chains should be active.

In dynamic SM power save mode, the STA enables its multiple receive chains when it receives the start of a frame exchange sequence addressed to it. Such a frame exchange sequence shall start with a single-spatial stream individually addressed frame that requires an immediate response and that is addressed to the STA in dynamic SM power save mode. An RTS/CTS sequence may be used for this purpose. The STA shall, subject to its spatial stream capabilities (see 9.4.2.56.4 and 9.4.2.158.3) and operating mode (see 11.42), be capable of receiving a PPDU that is sent using more than one spatial stream a SIFS after the end of its response frame transmission. The STA switches to the multiple receive chain mode when it receives the frame addressed to it and switches back immediately when the frame exchange sequence ends.

NOTE—A STA in dynamic SM power save mode cannot distinguish between an RTS/CTS sequence that precedes a MIMO transmission and any other RTS/CTS and, therefore, always enables its multiple receive chains when it receives the RTS addressed to it.

The STA can determine the end of the frame exchange sequence through any of the following:

- It receives an individually addressed frame addressed to another STA.
- It receives a frame with a TA that differs from the TA of the frame that started the TXOP.
- The CS mechanism (see 10.3.2.1) indicates that the medium is idle at the TxPIFS slot boundary (defined in 10.3.7).

In static SM power save mode, the STA maintains only a single receive chain active.

The STA may use the SM Power Save frame to communicate its SM power save state. The STA may also use SM Power Save subfield in the HT Capabilities element of its (Re)Association Request frame to achieve the same purpose. The latter allows the STA to use only a single receive chain immediately after (re)association.

A STA that has one or more DLS or TDLS links shall not operate in SM power save mode.

Changes to the number of active receive chains are made only after the SM power save mode indication has been successfully delivered (i.e., by acknowledgment of a frame carrying the HT Capabilities element or by acknowledgment of a SM Power Save frame). The SM power save mode indication shall be transmitted using an individually addressed frame.

11.2.7 Power management in a PBSS and DMG infrastructure BSS

11.2.7.1 General

Power save mechanisms in this subclause enable non-AP STAs to sleep for one or more beacon intervals or for parts of a beacon interval.

The non-AP and non-PCP STA power save mechanisms defined in 11.2.7.2 enable a non-AP and non-PCP STA to sleep after signaling the AP or PCP, or to sleep according to a periodic schedule that is negotiated with the AP or PCP. A non-AP and non-PCP STA may use both mechanisms in conjunction to increase its power save opportunity.

Similarly, the PCP power save mechanisms defined in 11.2.7.3 enable a PCP to sleep after signaling at least one non-AP and non-PCP STA, or to sleep according to a wakeup schedule that is available to all STAs associated with the PCP.

A non-AP STA can be in one of two power management modes:

- Active mode: The STA does not use any of the scheduled or unscheduled power save mechanisms defined in this subclause and operates in the awake state, except during time intervals that it determines it is not the target of any transmission by other STAs, where it may operate in doze state.
- Power save (PS) mode: The STA uses at least one of the scheduled or unscheduled power save mechanisms defined in this subclause and switches between awake and the doze states.

A non-AP STA shall be in active mode upon (re)association.

For scheduled power save, the DMG Wakeup Schedule element (9.4.2.131) is used to communicate the sleep and wakeup pattern of a DMG STA, referred to as the *STA wakeup schedule (WS)*. A STA wakeup schedule defines a periodic routine of cycling between a set of contiguous beacon intervals referred to as *awake BIs* and a set of contiguous beacon intervals referred to as *doze BIs*. The rules for alternating between awake and doze power states during awake BIs and doze BIs are defined in 11.2.7.2.3 and 11.2.7.3.3. An overview of these rules is given in Table 11-2 and Table 11-3.

A STA in PS mode that is following a wakeup schedule and has also exercised unscheduled power save shall follow the doze BI rules in this subclause and shall follow the ATIM rules in 11.2.7.4 for a non-AP STA without wakeup schedule.

An AP or PCP keeps track of the wakeup schedules of all associated non-AP and non-PCP STAs. A non-AP and non-PCP STA keeps track of the wakeup schedule of all associated non-AP and non-PCP STAs that it is communicating with. There is no end time to a wakeup schedule. Once a STA enters PS mode according to its wakeup schedule it stays indefinitely in PS mode until it leaves the PS mode through mechanisms defined in this subclause. Once a STA is made aware of the wakeup schedule of another STA, it is able to keep track of the wakeup schedule on its own. Each STA delivers traffic to a peer STA only when the peer STA is in awake state.

A STA that has transmitted a frame to an AP or PCP with which it is not associated and from which it expects a response shall remain in the awake state until such a response is received or until the procedure has timed out.

An AP shall buffer BUs addressed to non-AP STAs in doze state. The buffered BUs shall be transmitted only at designated times (11.2.7.2). A non-AP STA shall defer delivery of BUs addressed to other non-AP STAs in doze state. The BUs shall be transmitted only at designated times (11.2.7.2).

If a PCP sets the BSS Type field within a transmitted DMG Beacon frame to PBSS or the AP or PCP includes a Nontransmitted BSSID Capability element in a transmitted DMG Beacon, Announce, or Probe Response frames and the BSS Type field within the Nontransmitted BSSID Capability element is equal to PBSS, then the AP or PCP shall follow the PCP power management rules described in 11.2.7.3 if the AP or PCP chooses to employ power management.

An AP or PCP may include an Antenna Sector ID Pattern element in Power Save Configuration Response and Probe Response frames transmitted to a non-AP and non-PCP STA. If a non-AP and non-PCP STA uses the information contained in the Antenna Sector ID Pattern element received from its AP or PCP, then during the BTI of an awake BI, the STA might stay awake just to receive DMG Beacon frames transmitted through specific DMG antenna and sector and switch to doze state during other periods in the BTI.

Table 11-2 lists the power states for a non-AP and non-PCP STA in PS mode and a PCP in PS mode during an awake BI. Each entry indicates the state, either awake or doze, for the non-AP and non-PCP STA or the PCP in PS mode at various times during the awake BI.

Table 11-2—Power states for an awake BI

| Portion of the beacon interval | | PPS PCP | PS non-AP and non-PCP STA |
|--------------------------------|---|---------------|---------------------------|
| BHI | BTI | Awake | Awake or doze |
| | A-BFT | Awake | Awake or doze |
| | ATI | Awake | Awake |
| DTI | CBAP with the PCP Active field set to 1 in the schedule | Awake or doze | Awake or doze |
| | CBAP with the PCP Active field set to 0 in the schedule | Doze | Awake or doze |
| | SP with Destination AID set to broadcast AID | Awake | Awake |
| | Nontruncatable or nonextensible SP with non-PCP STA as Source AID or Destination AID | Awake or doze | Awake or doze |
| | Truncatable SP or extensible SP with non-AP and non-PCP STA (excluding the PS STA) as Source AID or Destination AID | Awake | Awake or doze |
| | SPs allocated to itself | Awake or doze | Awake or doze |
| | All other SPs | Awake or doze | Awake or doze |
| | Awake window | Awake | Awake |
| | DTI with CBAP Only subfield set to 1 | Awake or doze | Awake or doze |
| | Destination AID field of a CBAP equal to the broadcast AID in the schedule | Awake or doze | Awake or doze |

Table 11-3 lists the power states for a non-AP and non-PCP STA in PS mode and a PCP in PS mode during a doze BI. Each entry indicates the state, either awake or doze, for the non-AP and non-PCP STA or the PCP in PS mode at various times during the doze BI.

Table 11-3—Power states for a doze BI

| Portion of the beacon interval | | PPS PCP | PS non-AP and non-PCP STA |
|--|---|---------|---------------------------|
| BHI | BTI | N/A | Awake or doze |
| | A-BFT | N/A | Awake or doze |
| | ATI | Awake | Awake |
| DTI | CBAP with the PCP Active field set to 1 in the schedule | Doze | Doze |
| | CBAP with the PCP Active field set to 0 in the schedule | Doze | Doze |
| | SP with Destination AID set to broadcast AID | Doze | Doze |
| | SP with individually addressed destination AID | Doze | Awake |
| | Nontruncatable or nonextensible SP with non-PCP STA as Source AID or Destination AID | Doze | Doze |
| | Truncatable SP or extensible SP with non-AP and non-PCP STA (excluding the PS STA) as Source AID or Destination AID | Doze | Doze |
| | SPs allocated to itself | Doze | Doze |
| | All other SPs | Doze | Doze |
| | DTI with CBAP Only subfield set to 1 | Doze | Doze |
| Destination AID field of a CBAP equal to the broadcast AID in the schedule | | Doze | Doze |

The source DMG STA and the destination DMG STA of a nontruncatable SP or allocated CBAP with individually addressed destination AID may go to doze state within the SP or within the CBAP, respectively, after the source DMG STA transmitted a frame to the destination DMG STA of the SP or the CBAP, respectively, with the EOSP subfield set to 1 and received the following response frame from the destination DMG STA of the SP or the CBAP, respectively.

If the MM-SME Power Mode field within the MMS element sent by an MM-SME coordinated STA is 1, all STAs advertised in the MMS element shall switch to the doze state when the wakeup schedule of any one STA or a successful frame exchange as described in Annex G brings the STA to the doze state.

If the MM-SME Power Mode field within the MMS element sent by an MM-SME coordinated STA is 0, all STAs advertised in the MMS element shall switch to the awake state when the wakeup schedule of any one STA or a successful frame exchange as described in Annex G brings the STA to the awake state.

11.2.7.2 Non-AP and non-PCP STA power management mode

11.2.7.2.1 General

The power management mode of a non-AP and non-PCP STA is selected by the PowerManagementMode parameter of the MLME-POWERMGT.request primitive. Once the STA updates its power management mode, the MLME shall issue an MLME-POWERMGT.confirm primitive indicating the result of the operation. While the STA is in PS mode it may exercise the unscheduled and scheduled power save mechanisms described in this subclause.

Figure 11-9 illustrates a finite state machine that shows the state transition of a STA in active and PS mode, and also the transition between active and PS modes when the non-AP and non-PCP STA has set up a wakeup schedule.

NOTE—In Figure 11-9, the notations PSC-REQ(X) and PSC-RSP(Y) indicate that the PSC-REQ and PSC-RSP frames, respectively, are transmitted with the setting as indicated by their corresponding X and Y parameters. The transitions shown “As per T1” are defined in Table 11-2. The transitions shown “As per T2” are defined in Table 11-3.

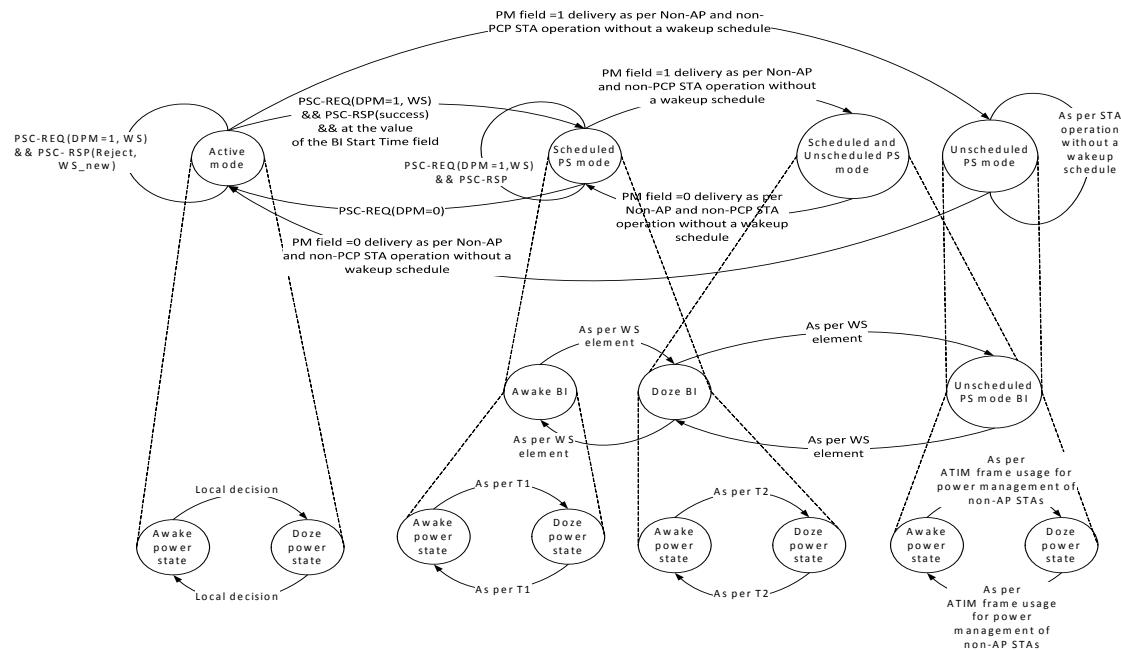

Figure 11-9—State transition diagram of non-AP and non-PCP STA in active and PS modes

11.2.7.2.2 Non-AP and non-PCP STA operation without a wakeup schedule

To change its power state without a wakeup schedule, a non-AP and non-PCP STA shall inform the AP or PCP by completing a successful frame exchange (as described in Annex G) that is initiated by the STA and that includes a Management frame, Extension frame or Data frame, and also an Ack or a BlockAck frame from the AP or PCP. The Power Management subfield(s) in the Frame Control field of the frame(s) sent by the STA in this exchange that contain a BU or are QoS Null frame indicate the power state that the STA shall adopt upon successful completion of the entire frame exchange. A non-AP and non-PCP STA shall not change its power state using a frame exchange that does not receive an Ack or BlockAck frame from the AP or PCP, or using a BlockAckReq frame.

A non-AP and non-PCP STA in doze state shall limit the frames it transmits to the following:

- A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from the AP or PCP, with the Power Management subfield in the Frame Control field of the frame set to 0, i.e., a frame to indicate the STA intent to transition out of unscheduled PS mode.
- A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from the AP or PCP, plus Ack and Block Ack frames that respond to the frames sent by the AP or PCP during the reverse direction grant, if the following conditions apply:
 - the Power Management subfield in the Frame Control field of the frame sent by the non-AP and non-PCP STA is set to 1

- the AP or PCP has transmitted a Capability Information field in which the Triggered Unscheduled PS subfield is equal to 1
- An RTS, DMG CTS-to-self, CF-End, Grant, BRP, SSW or SSW-Feedback frame.

NOTE—A DMG STA in doze state may need to perform beamforming to restore its links with other DMG STAs.

As long as there is at least one STA that has entered doze state through the unscheduled power save mechanism, the AP or PCP shall establish an awake window by transmitting an Awake Window element, and shall include a UPSIM element in every DMG Beacon and Announce frame it transmits. The AP or PCP may establish an awake window and/or include a UPSIM element in a DMG Beacon or Announce frame it transmits even if no STA is in doze state. The absence of a UPSIM element in a DMG Beacon or Announce frame is equivalent to presence of the UPSIM element in the frame with all bits of the Power Save Indication Bitmap field in the UPSIM element set to 0. The UPSIM element in every DMG Beacon or Announce frame transmitted by the AP or PCP shall indicate the power state of all STAs at the time of frame transmission.

NOTE—Transmitting a DMG Beacon frame with the Discovery Mode subfield set to 0, or an Announce frame, without including the UPSIM element in the frame, indicates that no STA is in unscheduled PS mode at the time of the frame transmission.

A non-AP and non-PCP STA may also indicate its power state to another non-AP and non-PCP STA through the Power Management subfield in the Frame Control field of any frame that contains all or part of a BU. The non-AP and non-PCP STA shall indicate its correct power state in the Frame Control field of any frame it transmits that contains all or part of a BU.

When a non-AP and non-PCP STA that has not set up a wakeup schedule with the AP or PCP enters PS mode, every beacon interval shall be an awake BI for that STA. A non-AP and non-PCP STA that has not set up a wakeup schedule with the AP or PCP and that is in PS mode shall be awake during any allocated SP for which the STA is either the source DMG STA or destination DMG STA during an awake BI. During an awake BI, a non-AP and non-PCP STA that has not set up a wakeup schedule with the AP or PCP and that is in PS mode shall be awake during any allocated CBAP for which the STA is the source DMG STA or destination DMG STA, or the source AID of the CBAP is equal to the broadcast AID or the destination AID of the CBAP is equal to the broadcast AID.

A non-PCP and non-AP STA that has used unscheduled power save to enter doze state may offer an RDG to its AP or PCP if the following conditions apply:

- the AP or PCP has transmitted a Capability Information field in which the Triggered Unscheduled PS field is equal to 1
- the non-AP and non-PCP has transmitted a Capability Information field in which the Reverse Direction subfield is equal to 1

The AP or the PCP may use the offered RDG to transmit one or more BUs to the non-PCP and non-AP STA using the reverse direction protocol defined in 10.28.

The non-PCP and non-AP STA should continue to offer an RDG to the AP or to the PCP within the current TXOP while the Buffered AC subfield of the QoS Control field in frames transmitted by the AP or by the PCP indicates that one or more BUs are buffered for the AC for which the TXOP was gained.

11.2.7.2.3 Non-AP and non-PCP STA operation with a wakeup schedule

To transition from active mode to PS mode, a non-AP and non-PCP STA that is associated with an AP or PCP shall establish a wakeup schedule (WS) with the AP or PCP. A WS is established with the AP or PCP following the successful transmission of a PSC-REQ frame to the AP or PCP with the DPM field set to 1 and an acknowledged receipt of the corresponding PSC-RSP frame from the AP or PCP provided that the PSC-RSP frame contained a status code indicating success. After receiving a PSC-RSP frame from the AP or PCP with a status code indicating success and responding with an acknowledgment, the STA switches to the

PS mode at the instant specified by the BI Start Time field of the DMG Wakeup Schedule element transmitted to the AP or PCP. In PS mode, the STA shall cycle between awake BIs and doze BIs following the WS that the STA has established with the AP or PCP.

As long as there is at least one STA that is in PS mode, the AP or PCP shall establish an awake window. The AP or PCP may include an Awake Window element in a DMG Beacon or Announce frame it transmits even if no STA in the BSS has entered PS mode.

A DMG Wakeup Schedule element shall be included in any PSC-REQ frame that the STA transmits to the AP or PCP as an explicit request for a WS. An Awake Window element may also be included in the same PSC-REQ frame to indicate a requested duration for the awake window. If the AP or PCP accepts the proposed WS and the optionally present awake window duration in the PSC-REQ frame, it shall reply with a PSC-RSP frame indicating a status code of SUCCESS. Otherwise, it shall respond with a PSC-RSP frame with a status code indicating the reason for rejecting the request. The AP or PCP may suggest an alternative WS and optionally an awake window duration in the PSC-RSP frame and set the status code to REJECT_WITH_SCHEDULE. If the STA accepts the alternative WS, it shall include this WS in a subsequently transmitted PSC-REQ frame. If the non-AP and non-PCP STA does not accept the alternative WS, it shall not send a PSC-REQ frame for dot11PSRequestSuspensionInterval beacon intervals following the receipt of the PSC-RSP frame from the AP or PCP.

NOTE 1—The AP or PCP can recommend an alternative WS, for example to align the awake BIs of some or all non-AP and non-PCP STAs.

NOTE 2—The awake window duration sent by the AP or PCP in a PSC-RSP frame is to assist the STA for awake window planning. The awake window duration is always set by the Awake Window element in the most recent DMG Beacon or Announce frame received from the AP or PCP.

If a non-AP and non-PCP STA has established a WS with the AP or PCP and the non-AP and non-PCP STA is in PS mode, the non-AP and non-PCP STA shall have m successive awake BIs repeating every n beacon interval, where n is the value of the Sleep Cycle field of the DMG Wakeup Schedule element contained in the PSC-RSP frame received from the AP or PCP during the frame exchange that established the WS, and m is the value of the Number of Awake BIs field in the DMG Wakeup Schedule element contained in that PSC-RSP frame. During each of its awake BIs, the non-AP and non-PCP STA shall be awake during the awake window if it is present, and during all allocated SPs in which it is either the source or destination DMG STA.

An AP or PCP may send an unsolicited PSC-RSP frame without a WS and indicating a status code of success to a non-AP and non-PCP STA in PS mode. Upon receiving the unsolicited PSC-RSP frame meeting these conditions, the non-AP and non-PCP STA shall switch to active mode.

11.2.7.2.4 Non-AP and non-PCP STA operation with or without a wakeup schedule

A non-AP and non-PCP STA in PS mode shall stay awake for dot11MinBHIDuration starting from the beginning of each awake BI and may switch to the doze state after the expiration of this time. The only exception is when the Power Save Configuration Response or Probe Response frame received from the AP or PCP includes an Antenna Sector ID Pattern element, in which case the non-AP and non-PCP STA may use the Antenna Sector ID Pattern element to receive DMG Beacon frames transmitted through a specific DMG antenna and sector, and may switch to doze state during other periods in the BTI.

An AP or PCP shall transmit SP allocation announcements for STAs in PS mode during each of the STAs' awake BIs and may transmit those SP allocation announcements in other beacon intervals. New SPs shall be allocated to begin either within or after the later awake BI of the source DMG STA and destination DMG STA of the SP.

To transition from PS mode to active mode, a non-AP and non-PCP STA that has an established WS with the AP or PCP shall send a PSC-REQ frame with the DPM field set to 0 to the AP or PCP and enter active

mode following the reception of the Ack frame response. The AP or PCP shall not send a PSC-RSP frame if the DPM field is 0 in the PSC-REQ frame.

In order for a STA to learn the WS of another STA within the BSS, the STA may send an Information Request frame to the other STA or to the AP or PCP as defined in 11.30.1. The AP or PCP maintains a WS distribution table for the lifetime of the BSS, and upon receiving an Information Request frame that contains a request for the WS of a STA identified by the Subject Address field within the frame, shall add an entry to the WS distribution table made up of the STA that transmitted the Information Request frame (the requesting STA) and the STA identified by the Subject Address field within the Information Request frame (the target STA). If the AP or PCP moves the TBTT, changes the duration of the beacon interval, or resets the TSF, the AP or PCP shall transmit an unsolicited Information Response frame with the updated DMG Wakeup Schedule element. When transmitting the DMG Wakeup Schedule element for a STA that is in PS mode, the transmitting STA shall use a value for the BI Start Time field that points to a TBTT that is earlier, but not more than 2^{31} μ s minus aDMGDWSValidPeriod earlier, than the TBTT of the beacon interval during which the BI Start Time field is transmitted, so that the receiving STA can correctly identify the power management mode of the STA the WS belongs to.

If the Information Request frame is transmitted to the AP or PCP and the STA indicated in the Information Request's Subject Address field does not have an established WS with the AP or PCP, the AP or PCP shall set the length of the DMG Wakeup Schedule element to 0 in the Information Response frame.

11.2.7.3 PCP power management mode

11.2.7.3.1 General

The power management mode of a PCP is selected by the PowerManagementMode parameter of the MLME-POWERMGT.request primitive. Once the PCP updates its power management mode, the MLME shall issue an MLME-POWERMGT.confirm primitive indicating the result of the operation. While the PCP is in PS mode it may exercise the unscheduled and scheduled power save mechanisms described in this subclause.

11.2.7.3.2 PCP operation without a wakeup schedule

To change its power state without a wakeup schedule, the PCP shall include a UPSIM element in or remove the UPSIM element from every DMG Beacon frame with the Discovery Mode subfield set to 0 and Announce frame that it transmits, and shall indicate its new power state in the UPSIM element if it is included in the frame

NOTE—The UPSIM element in a DMG Beacon frame with the Discovery Mode subfield set to 0, or in an Announce frame, includes the power state of the PCP at the time of the frame transmission. Transmitting a DMG Beacon frame with the Discovery Mode subfield set to 0 or an Announce frame, without including the UPSIM element in the frame, indicates that no STA (including the PCP) is in unscheduled PS mode at the time of the frame transmission.

Alternatively, to change its power state without a wakeup schedule, the PCP shall inform all associated STAs by completing a successful frame exchange (as described in Annex G) that is initiated by the PCP and that includes a Management frame, Extension frame or Data frame, and also an Ack or a BlockAck frame from the associated STA. The Power Management subfield(s) in the Frame Control field of the frame(s) sent by the PCP in this exchange that contain a BU or are QoS Null frame indicate the power state that the PCP shall adopt upon successful completion of the entire frame exchange. The PCP shall not change its power state using a frame exchange that does not receive an Ack or BlockAck frame from the associated STA, or using a BlockAckReq frame.

When attempting to enter doze state, the PCP shall not enter doze state unless it has received an Ack or BlockAck from each associated STA. When attempting to leave doze state, the PCP shall enter awake state as soon as it receives an Ack or BlockAck from one associated STA.

A PCP in doze state shall limit the frames it transmits to the following:

- A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from a non-AP and non-PCP STA, with the Power Management subfield in the Frame Control field of the frame set to 0, i.e., a frame to indicate the PCP intent to transition out of unscheduled PS mode.
- A Management, Extension or Data frame that triggers an Ack or a BlockAck frame from a non-AP and non-PCP STA, plus Ack and BlockAck frames that respond to the frames sent by the non-AP and non-PCP STA during the reverse direction grant, if the following conditions apply:
 - the Power Management subfield in the Frame Control field of the frame sent by the PCP is set to 1
 - the non-AP and non-PCP STA has transmitted a Capability Information field in which the Triggered Unscheduled PS subfield is equal to 1
- An RTS, DMG CTS-to-self, CF-End, Grant, BRP, SSW or SSW-Feedback frame.

NOTE—A DMG STA in doze state may need to perform beamforming to restore its links with other DMG STAs.

The PCP shall indicate the correct power state in the Frame Control field of any frame it transmits to an associated STA that contains all or part of a BU.

11.2.7.3.3 PCP operation with a wakeup schedule

A PCP in PPS mode (PPS PCP) may enter the doze state for one or more consecutive beacon intervals in order to minimize its energy consumption. Figure 11-10 illustrates a finite state machine that shows the state transition of the PCP power management mode.

NOTE—Figure 11-10 uses the following terminology: “As per T1” means that the transitions are specified in Table 11-2, “As per T2” means that the transitions are specified in Table 11-3.

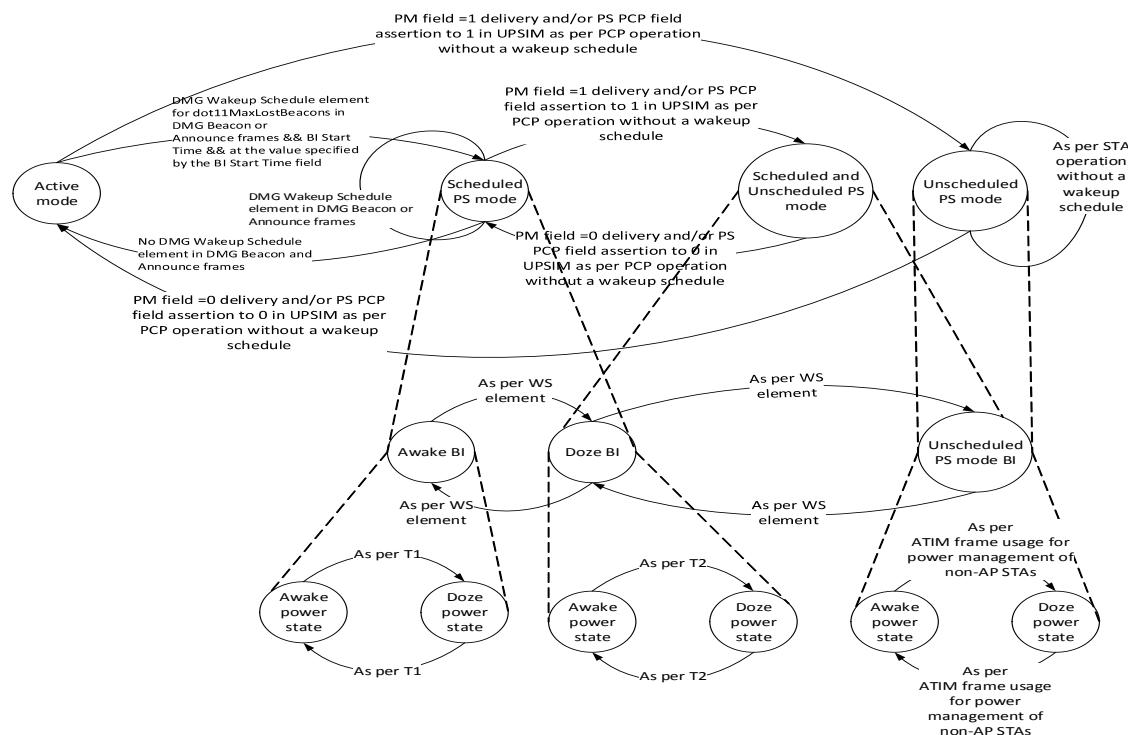

Figure 11-10—State transition diagram of PCP power management mode

To enter PPS mode, or to modify an established WS, the PCP announces a WS through a DMG Wakeup Schedule element (9.4.2.131) included in a DMG Beacon, Announce, or any Action frame.

The PCP can assume that all associated STAs have received a WS and the Awake Window element that can optionally be transmitted with the WS at the earlier of the following events:

- The PCP has transmitted the DMG Wakeup Schedule element in DMG Beacon or Announce frames for at least dot11MaxLostBeacons successive beacon intervals.
- The PCP has confirmed that each associated STA has received the DMG Wakeup Schedule element by receiving an ACK or a response frame from each associated STA in response to a request frame that includes the DMG Wakeup Schedule element.

The first PCP Awake BI of a sleep cycle in a WS starts at the instant specified by the value of the BI Start Time field of the announced DMG Wakeup Schedule element, and the number of successive PCP Awake BIs is specified by the Number of Awake BIs field of the DMG Wakeup Schedule element. Once in PPS mode, the PCP transitions between awake BI and doze BI according to the WS it has established.

NOTE—The PCP may need to behave as it is in active mode or in an awake BI to some associated STAs for a number of planned successive PCP doze BIs if it has not been able to confirm the reception of its WS by each associated STA, and it has not transmitted its WS through DMG Beacon or Announce frames over dot11MaxLostBeacons successive beacon intervals.

In order to transition from PPS mode to active mode, the PCP stops including the DMG Wakeup Schedule element in DMG Beacon and Announce frames. A DMG STA that has received a PCP WS shall assume the PCP WS is in effect until it either receives a DMG Beacon or Announce frame that does not include a DMG Wakeup Schedule element or receives a different PCP WS.

In a PCP doze BI, the PCP should schedule a BTI or ATI. If scheduling an ATI, the PCP should transmit an Announce frame during the ATI to associated STAs.

NOTE—The PCP provides the PBSS timing synchronization function (TSF). Transmitting frequent TSF information through DMG Beacon or Announce frames is important when there are non-PCP STAs in the PBSS that rely on TSF information to communicate directly with each other.

The PCP may include in the Extended Schedule element the schedule for the beacon intervals during the PCP doze BIs. The PCP may schedule a SP or CBAP within a doze BI by setting the Allocation Start field of the new SP or CBAP in the Extended Schedule element to a value within a doze BI. If the Extended Schedule element is transmitted, the PCP shall transmit it at least dot11MaxLostBeacons times before the PPS PCP enters the doze state.

The PCP shall check that the schedule of pseudo-static allocations transmitted in the last Extended Schedule element before the PCP entered PPS mode is valid during the PCP doze BIs. Thus, a STA participating in such a pseudo-static allocation assumes that the allocation is present during the following consecutive PCP doze BIs.

The PCP may enter and remain in the doze state for any portion of an SP if it is not a source or a destination of the SP. The PCP shall remain in the awake state for any portion of a truncatable or extendable SP (9.4.2.132). The availability of the PCP during a CBAP in the awake BI shall be announced by setting the PCP Active subfield within the Allocation Control field to 1 for a CBAP allocation made through the Extended Schedule element.

NOTE—A PCP that indicates availability during a CBAP that includes an awake window can exchange ATIM frames with non-AP and non-PCP STAs during the awake window and possibly enter the doze state for the remainder of the CBAP outside the awake window (see 11.2.7.4).

Figure 11-11 shows an example of the basic operation of a PCP in PPS mode when the PCP sleep interval equals one beacon interval (i.e., PCP sleeps every other beacon interval) and the PCP sleep interval starts

right after the first beacon interval. In this example, the first beacon interval and the second beacon interval have the same schedule, but the third beacon interval and the fourth beacon interval have different schedules. The first beacon interval is the awake BI in which the PPS PCP is in the awake state to serve non-PCP STAs. In the first beacon interval, the PCP transmits the Extended Schedule element for the current beacon interval with the pseudo-static subfield set to 1 for all allocations within the Extended Schedule element to indicate that the schedule of the first beacon interval also applies to the second beacon interval. In addition, the PCP transmits the DMG Wakeup Schedule element with the information of the start time and the length of the PCP sleep interval, and the STA Availability element to indicate the availability of the PCP for the CBAP of the awake BI. Following the CBAP of the first beacon interval, the PCP enters the doze state and sleeps for more than one beacon interval. The PCP switches from the doze state to the awake state after sleeping through the remainder of the first beacon interval and through the entire second beacon interval, which is the start of the third beacon interval in Figure 11-11. Since in this example the schedule of the third beacon interval and the fourth beacon interval are different, the PCP transmits the Extended Schedule element containing the individual allocations for the third beacon interval and fourth beacon interval. The PCP enters the doze state after it completes all exchanges in the third beacon interval and wakes up at the start of the fifth beacon interval.

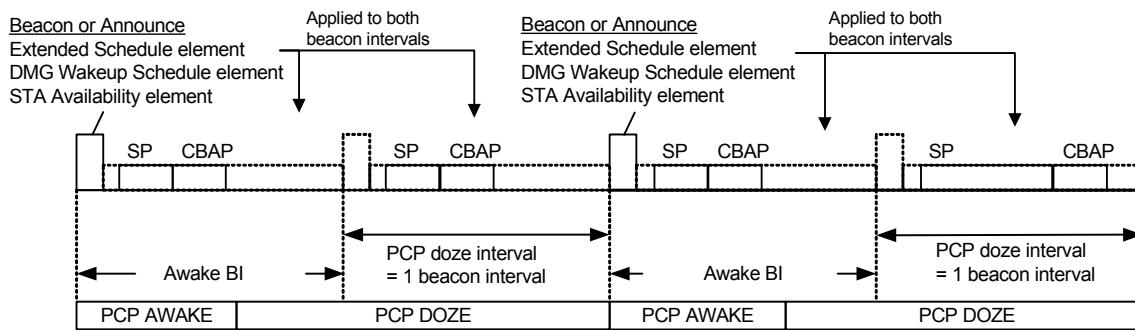

Figure 11-11—Example operation of PPS mode

11.2.7.4 ATIM frame usage for power management of non-AP STAs

An awake window is present within the first CBAP of a beacon interval that is scheduled through the Extended Schedule element and has the Source AID and Destination AID fields in that Extended Schedule element equal to the broadcast AID, or in a CBAP that is scheduled through the CBAP Only field in the DMG Parameters field (9.4.1.47) set to 1, for dot11MaxLostBeacons beacon intervals following the most recent transmission of the Awake Window element (9.4.2.137) by the AP or PCP with the Awake Window Duration field set to a nonzero value.

NOTE—Transmission rules during the awake window are the same as the transmission rules for the CBAP that the awake window belongs to.

A non-AP and non-PCP STA delivers the Awake Window element to an AP or PCP as defined in 11.2.7.2.3. An AP or PCP delivers the Awake Window element to a non-AP and a non-PCP STA as defined 11.2.7.3.

If present, the awake window starts from the beginning of a CBAP and has a duration that is defined by the value of the Awake Window Duration field in the Awake Window element or the CBAP duration, whichever is smaller. During the awake window, a STA shall transmit only ATIM frames. A DMG STA in PS mode shall be in the awake state during each awake window that lies within each awake BI for that STA.

BUs that are to be transmitted to a STA that is in PS mode are first announced through ATIM frames during the awake window. A STA in PS mode that is awake during an awake window shall listen for these announcements to determine if it needs to change its power state. If during the awake window the STA does not receive or transmit an ATIM frame with BSSID equal to the BSSID of the BSS of the STA is a member,

then it may enter the doze state at the end of the awake window. If a STA receives an ATIM frame during the awake window, it shall acknowledge the ATIM frame. Any two STAs that successfully complete an ATIM frame exchange with each other during the awake window become peer STAs.

A STA that is in PS mode and following a wakeup schedule and has not performed unscheduled power save to enter doze state and receives an ATIM frame during the awake window shall be awake during allocations within the current beacon interval that have the Source AID equal to broadcast AID or have a Source AID that identifies a STA whose MAC address is equal to the TA field of the received ATIM frame, or during any DTI that is scheduled through the CBAP Only field in the DMG Parameters field (9.4.1.47) set to 1. If a STA transmits an ATIM frame during the awake window, it shall attempt to deliver its BUs during allocations within the current beacon interval that have a Destination AID equal to broadcast AID or have a Destination AID that identifies a STA whose MAC address is equal to the RA field of the transmitted ATIM frame, or during any DTI that is scheduled through the CBAP Only field in the DMG Parameters field (9.4.1.47) set to 1. A STA that receives or transmits an ATIM frame during the awake window may enter the doze state when it has successfully transmitted to and received from all corresponding peer STAs for this beacon interval a QoS Data frame with the EOSP subfield set to 1; otherwise it shall stay active until the end of the current beacon interval. ATIM frame transmissions and MSDU transmissions follow the rules defined in 11.2.8.

NOTE—A STA that has performed unscheduled power save to enter doze state and receives an ATIM frame during an awake window can use the unscheduled power save mechanism to leave doze state following the procedure in 11.2.7.2.2 or 11.2.7.3.2.

Figure 11-12 illustrates an example of a DMG STA response to an ATIM frame. For illustration purposes the 5 beacon intervals shown in the figure are numbered from 0 to 4. The PCP is following a wakeup schedule, with 1 awake BI out of every 4 beacon intervals. The non-PCP STA A is also following a wakeup schedule, with 1 awake BI out of every 2 beacon intervals. In addition, STA A performs unscheduled power save during BI 0, and also during BI 2 through BI 4. STA A is required to stay awake during the following CBAP after receiving an ATIM frame in BI 2. An ATIM frame received during BI 4 however serves as a traffic indication and PCP will transmit frames to STA A only after STA A has performed unscheduled power save to leave doze state.

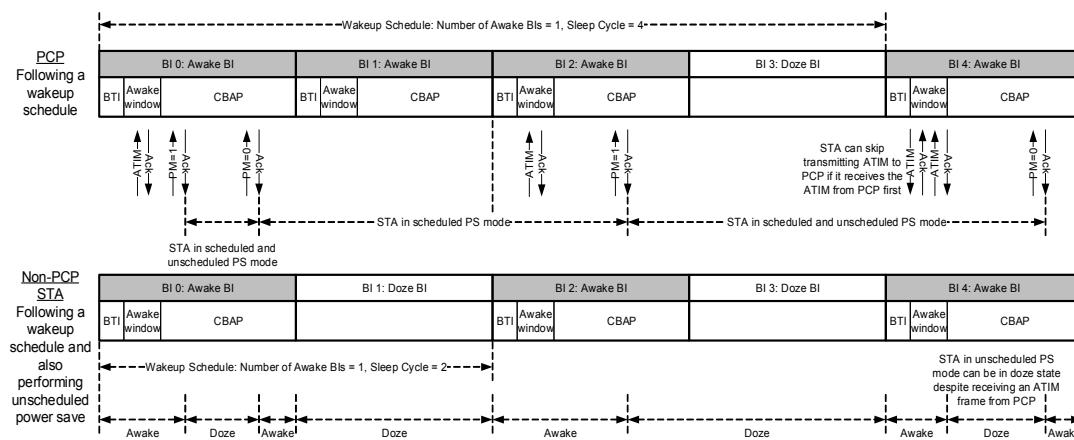

Figure 11-12—Example of ATIM frame response behavior in PS mode

The ATIM frame transmission result and EOSP notification result between a MAC address pair can be used for other MAC pairs that are members of the same MMSL cluster.

11.2.8 ATIM frame and frame transmission in IBSS, DMG infrastructure BSS, and PBSS

If power management is in use within an IBSS, a STA shall buffer individually addressed BUs for STAs that are known to be in PS mode.

The following rules describe operation of the ATIM frame and frame transmission to STAs in PS mode in an IBSS, DMG infrastructure BSS and PBSS:

- a) Following the reception or transmission of the Beacon frame in a non-DMG IBSS, during the ATIM window, the STA shall queue for transmission an individually addressed ATIM frame to each STA for which it has one or more buffered individually addressed BUs and for which an ATIM frame is not already queued. Following the BTI or ATI in a DMG BSS, during the Awake Window, the STA shall queue for transmission an individually addressed ATIM frame to each STA for which it has one or more buffered individually addressed BUs and for which an ATIM frame is not already queued. If the STA has one or more buffered group addressed MSDUs (excluding those with a service class of StrictlyOrdered) or has one or more buffered group addressed MMPDUs, it shall queue for transmission an appropriately addressed group addressed ATIM frame if such an ATIM frame is not already queued.
- b) In a non-DMG IBSS, a STA shall use the backoff procedure defined in 10.3.4.3 for transmission of the first ATIM frame following the Beacon frame. In a DMG BSS, a STA shall use the backoff procedure defined in 10.3.4.3 for transmission of the first ATIM frame following the BTI or ATI. All remaining ATIM frames shall be transmitted using the DCF (for non-QoS STAs) or the EDCAF (for QoS STAs).
- c) ATIM frames shall be transmitted only during the ATIM window/Awake Window.
- d) A non-DMG STA shall transmit no frame types other than RTS, CTS, Ack, Beacon, ATIM and (QoS) Null frames during the ATIM window.
- e) Individually addressed ATIM frames shall be acknowledged. If no acknowledgment is received, the ATIM frame shall be retransmitted using either the DCF (for non-QoS STAs) or the EDCAF (for QoS STAs). Group addressed ATIM frames shall not be acknowledged.
- f) If a STA is unable to transmit an ATIM frame during the ATIM window/Awake Window, for example due to contention with other STAs, the STA should retain the buffered BUs and either discard the ATIM frame or attempt to transmit the ATIM frame during the next ATIM window/Awake Window.
- g) Immediately following the ATIM window/Awake Window, a STA shall begin transmission of any buffered group addressed frames for which an ATIM frame was previously transmitted. Following the transmission of any group addressed frames, any BUs addressed to STAs for which an acknowledgment for a previously transmitted ATIM frame was received shall be transmitted. A STA shall use the backoff procedure defined in 10.3.4.3 for transmission of the first frame following the ATIM window/Awake Window. All remaining frames shall be transmitted using either the DCF (for non-QoS STAs) or the EDCAF (for QoS STAs).
- h) If a buffered BU is transmitted using fragmentation and if the BU has been partially transmitted when the next Beacon frame is sent in a non-DMG IBSS or when the next beacon interval begins in a DMG BSS, the STA shall retain the buffered BU and announce the remaining fragments by transmitting an ATIM frame during the next ATIM window/Awake Window.
- i) If a STA is unable to transmit a buffered BU during the beacon interval in which it was announced, for example due to contention with other STAs, the STA shall retain the buffered BU and announce the BU again by transmitting an ATIM frame during the next ATIM window/Awake Window.
- j) Following the transmission of all buffered BUs, a STA may transmit BUs without announcement to STAs that are known to be in the awake state for the current beacon interval.
- k) A STA may discard BUs buffered for later transmission to power-saving STAs if the STA determines that the BU has been buffered for an excessive amount of time or if other conditions internal to the STA implementation make it desirable to discard buffered BUs (e.g., buffer

starvation). A BU should not be discarded that has been buffered for less than dot11BeaconPeriod. The algorithm to manage this buffering is beyond the scope of this standard.

- I) In order to indicate its intent to change power management modes, a STA shall transmit individually addressed or group addressed (QoS) Null frames within the ATIM window.

The STA shall not transition into or out of PS mode unless it has received acknowledgments from all recipients to which individually addressed (QoS) Null frames have been transmitted or after it has transmitted a sufficient number of group addressed (QoS) Null frames.

NOTE—The choice between individually addressed and group addressed transmissions, the peer STAs addressed for individually addressed transmissions, and the number of transmissions for group addressed transmissions are implementation choices outside the scope of the standard. A STA might base its choices on factors such as the number of peer STAs it is aware of in the IBSS, the expected traffic from each of these peer STAs, and the reliability of frame exchanges with these peer STAs.

11.3 STA authentication and association

11.3.1 State variables

A STA (local) for which dot11OCBActivated is false keeps an enumerated state variable for each STA (remote) with which direct communication via the WM is needed. In this context, direct communication refers to the transmission of any Class 2 or Class 3 frame with an Address 1 field that matches the MAC address of the remote STA.

A STA for which dot11MeshActivated is true (i.e., a mesh STA) does not use procedures described in 11.3.5. Instead, a mesh STA uses a mesh peering management protocol (MPM) or a authenticated mesh peering exchange (AMPE) to manage states and state variables for each peer STA. See 14.3 and 14.5 for details.

A STA for which dot11OCBActivated is true does not use MAC sublayer authentication or association and does not keep this state variable.

For nonmesh STAs, this state variable expresses the relationship between the local STA and the remote STA. It takes on the following values:

- *State 1*: Initial start state for non-DMG STAs and for DMG STAs that perform IEEE 802.11 authentication. Unauthenticated and unassociated.
- *State 2*: Initial start state for DMG STAs that do not perform IEEE 802.11 authentication. Authenticated (except DMG STAs that do not perform IEEE 802.11 authentication, which are unauthenticated) but unassociated.
- *State 3*: Authenticated (except DMG STAs that did not perform IEEE 802.11 authentication, which are unauthenticated) and associated (Pending RSNA Authentication). The IEEE 802.1X Controlled Port is blocked.
- *State 4*: Authenticated (except DMG STAs that did not perform IEEE 802.11 authentication, which are unauthenticated) and associated (RSNA Established or Not Required). The IEEE 802.1X Controlled Port is unblocked, or not present.

The state variable is kept within the MLME (i.e., is written and read by the MLME). The SME may also read this variable using the MLME-GETAUTHASSOCIATE.request primitive.

Mesh STAs manage the state variable as described in 14.3.2.

11.3.2 State transition diagram for nonmesh STAs

Figure 11-13 shows the state transition diagram for nonmesh STA states. Note that only events causing state changes are shown. The state of the sending STA given by Figure 11-13 is with respect to the intended receiving STA.

NOTE—A transition to State 1 might occur for other reasons such as no frames having been received from a STA for a period of time.

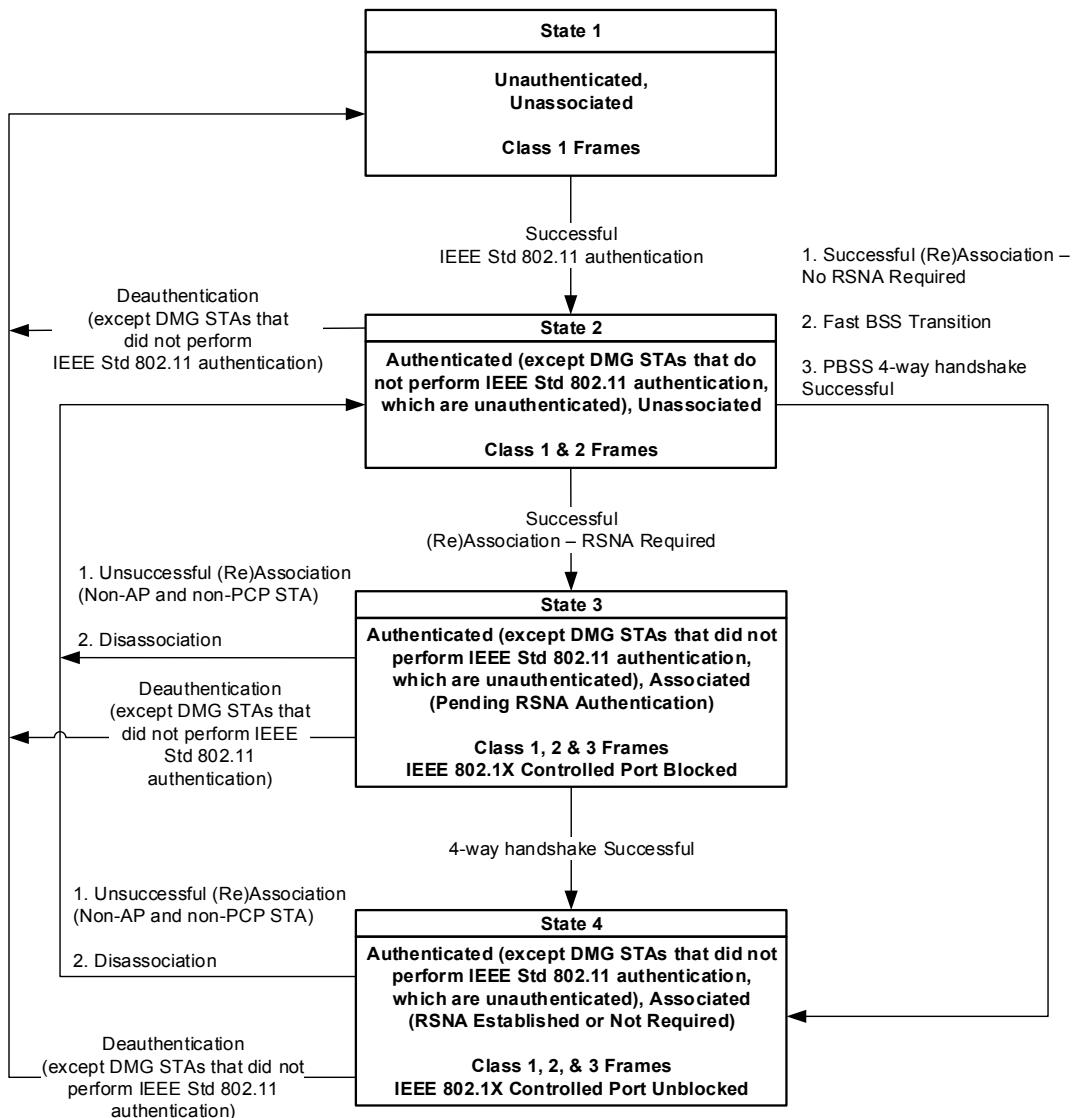

Figure 11-13—Relationship between state and services between a given pair of nonmesh STAs

11.3.3 Frame filtering based on STA state

The current state existing between the transmitter and receiver STAs determines the IEEE 802.11 frame types that may be exchanged between that pair of STAs (see Clause 9). A unique state exists for each pair of transmitter and receiver STAs. The allowed frame types are grouped into classes and the classes correspond to the STA state. In State 1, only Class 1 frames are allowed. In State 2, either Class 1 or Class 2 frames are

allowed. In State 3 and State 4, all frames are allowed (Classes 1, 2, and 3). In the definition of frame classes, the following terms are used:

- Within an infrastructure BSS: both the transmitting STA and the recipient STA participate in the same infrastructure BSS
- Within a PBSS: both the transmitting STA and the recipient STA participate in the same PBSS
- Within an IBSS: both the transmitting STA and the recipient STA participate in the same IBSS
- dot11RSNAActivated: reference to the setting of dot11RSNAActivated at the STA that needs to determine whether a transmission or reception is permitted.

NOTE—The phrase “within a BSS” comprises “within a PBSS,” “within an IBSS,” “within a MBSS,” or “within an infrastructure BSS.”

STA A participates in the same infrastructure BSS as STA B if at least one of the following conditions is met:

- STA A is associated with STA B, and either STA A or STA B is an AP.
- STA A receives a frame with the value of its TA field equal to the MAC address of STA B and with the value of its BSSID field equal to the BSSID of the BSS with which STA A is associated.
- STA A receives an Information Response frame from the AP with which it is associated containing an explicit indication that STA B is a member of the BSS with which STA A is associated.

STA A participates in the same PBSS as STA B if at least one of the following conditions is met:

- STA A is associated with STA B, and either STA A or STA B is a PCP.
- STA A receives a frame with the value of its TA field equal to the MAC address of STA B and with the value of its BSSID field equal to the BSSID of the PBSS that STA A has joined or started.
- STA A receives a frame, i.e., an Information Response frame, from its PCP containing an explicit indication that STA B is a member of the PBSS that STA A has joined.

STA A participates in the same IBSS as STA B if STA A receives a frame with the value of its TA field equal to the MAC address of STA B and with the value of its BSSID field equal to the BSSID of the IBSS that STA A has joined or started.

The frame classes are defined as follows:

- a) Class 1 frames
 - 1) Control frames
 - i) RTS
 - ii) CTS
 - iii) DMG Clear to send (DMG CTS)
 - iv) Ack
 - v) Grant
 - vi) SSW
 - vii) SSW-Feedback
 - viii) SSW-Ack
 - ix) Grant Ack
 - x) CF-End +CF-Ack
 - xi) CF-End
 - xii) In an IBSS and in a PBSS when dot11RSNAActivated is false, Block Ack (BlockAck)
 - xiii) In an IBSS and in a PBSS when dot11RSNAActivated is false, Block Ack Request (BlockAckReq)

- 2) Management frames
 - i) Probe Request/Response
 - ii) Beacon
 - iii) Authentication
 - iv) Deauthentication
 - v) ATIM
 - vi) Public Action
 - vii) Self-protected Action
 - viii) In an IBSS, all Action frames and all Action No Ack frames
 - ix) Unprotected DMG Action frames
 - x) In a DMG BSS, Link Measurement Request and Link Measurement Report frames
 - xi) In a PBSS when dot11RSNAActivated is false, all Action and Action No Ack frames except the following frames:
 - 1) ADDTS Request
 - 2) ADDTS Response
 - 3) DELTS
 - 3) Data frames
 - i) Data frames between IBSS STAs
 - ii) Data frames between peers using DLS
 - iii) Data frames within a PBSS
 - 4) Extension frames
 - i) DMG Beacon
- b) Class 2 frames
- 1) Management frames
 - i) Association Request/Response
 - ii) Reassociation Request/Response
 - iii) Disassociation
- c) Class 3 frames
- 1) Data frames
 - i) Data frames between STAs in an infrastructure BSS or in an MBSS
 - 2) Management frames
 - i) In an infrastructure BSS, an MBSS, or a PBSS, all Action and Action No Ack frames except those that are declared to be Class 1 or Class 2 frames
 - 3) Control frames
 - i) PS-Poll
 - ii) Poll
 - iii) SPR
 - iv) DMG DTS
 - v) Block Ack (BlockAck), except those that are declared to be Class 1
 - vi) Block Ack Request (BlockAckReq), except those that are declared to be Class 1 (above)

Class 2 and Class 3 frames are not allowed in an IBSS. If an IBSS STA receives a Class 2 or Class 3 frame, it shall ignore the frame.

A STA shall not transmit Class 2 frames unless in State 2 or State 3 or State 4.

A STA shall not transmit Class 3 frames unless in State 3 or State 4.

A multi-band capable device that uses OCT to move from State 2 to either State 3 or State 4 shall not transmit frames before the transmitting STA becomes over-the-WM enabled (see 11.33.4).

The use of the word “receive” in 11.3 refers to a frame that meets all of the filtering criteria specified in Clause 12 and Clause 10.

11.3.4 Authentication and deauthentication

11.3.4.1 General

This subclause describes the procedures used for IEEE 802.11 authentication and deauthentication. The states used in this description are defined in 11.3.1.

Successful authentication sets the STA’s state to State 2, if it was in State 1. Unsuccessful authentication leaves the STA’s state unchanged.

Deauthentication notification sets the STA’s state to State 1. Deauthentication notification when in State 3 or 4 implies disassociation as well. A STA may deauthenticate a peer STA at any time, for any reason.

If STA A in an infrastructure BSS receives a Class 2 or Class 3 frame from STA B that is not authenticated with STA A (i.e., the state for STA B is State 1), STA A shall discard the frame. If the frame has an individual address in the Address 1 field, the MLME of STA A shall send a Deauthentication frame to STA B.

Authentication is optional in an IBSS. In a non-DMG infrastructure BSS, authentication is required. In a DMG infrastructure BSS and PBSS, the Open System authentication algorithm is not used (see 12.3.3.1). APs do not initiate authentication.

11.3.4.2 Authentication—originating STA

Upon receipt of an MLME-AUTHENTICATE.request primitive that is part of an on-channel tunneling (see 11.33.4), the originating STA shall follow the rules in 11.33.4 in addition to the authentication procedure described below.

Upon receipt of an MLME-AUTHENTICATE.request primitive, the originating STA shall authenticate with the indicated STA using the following procedure:

- a) If the STA is in an IBSS, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 12.6.18).
- b) The STA shall execute one of the following:
 - 1) For the Open System or Shared Key authentication algorithm, the authentication mechanism described in 12.3.3.2 or 12.3.3.3, respectively.
 - 2) For the fast BSS transition (FT) authentication algorithm in an ESS, the authentication mechanism described in 13.5, or, if resource requests are included, 13.6.
 - 3) For SAE authentication in an infrastructure BSS, IBSS, or MBSS, the authentication mechanism described in 12.4.

- c) If the authentication was successful within the AuthenticateFailureTimeout, the state for the indicated STA shall be set to State 2 if it was State 1; the state shall remain unchanged if it was other than State 1.
- d) The MLME shall issue an MLME-AUTHENTICATE.confirm primitive to inform the SME of the result of the authentication.

11.3.4.3 Authentication—destination STA

Upon receipt of an Authentication frame with authentication transaction sequence number equal to 1, the destination STA shall authenticate with the originating STA using the following procedure:

- a) If Open System or Shared Key authentication algorithm is being used, the STA shall execute the procedure described in 12.3.3.2 or 12.3.3.3, respectively. These result in the generation of an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request.
- b) If FT authentication is being used, the MLME shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request, including the FT Authentication Elements, and the SME shall execute the procedure as described in 13.5 or 13.6.
- c) If SAE authentication is being used in an infrastructure BSS, IBSS, or MBSS, the MLME shall issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request, including the SAE authentication elements, and the SME shall execute the procedure as described in 12.4.
- d) If the STA is in an IBSS and management frame protection was not negotiated when the PTKSA(s) were created, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the originating STA by using the MLME-DELETEKEYS.request primitive (see 12.6.18).
- e) Upon receipt of an MLME-AUTHENTICATE.response primitive, if the ResultCode is not SUCCESS, the MLME shall transmit an Authentication frame with the corresponding status code, as defined in 9.4.1.9, and the state for the originating STA shall be left unchanged. The Authentication frame is constructed using the appropriate procedure in 12.3.3.2, 12.3.3.3, 13.5 or 13.6.
- f) Upon receipt of an MLME-AUTHENTICATE.response primitive, if the ResultCode is SUCCESS, the MLME shall transmit an Authentication frame that is constructed using the appropriate procedure in 12.3.3.2, 12.3.3.3, 13.5 or 13.6, with a status code of SUCCESS, and the state for the originating STA shall be set to State 2 if it was in State 1.

If the STA is in an IBSS, if the SME decides to initiate an RSNA, and if the SME does not know the security policy of the peer, it may issue an individually addressed Probe Request frame to the peer by invoking an MLME-SCAN.request primitive to discover the peer's security policy.

11.3.4.4 Deauthentication—originating STA

The originating STA shall deauthenticate with the indicated STA using the following procedure:

- a) The SME shall generate an MLME-DEAUTHENTICATE.request primitive containing the appropriate reason code for the STA deauthentication, as defined in Table 9-45 of 9.4.1.7.
- b) On receipt of the MLME-DEAUTHENTICATE.request primitive, if the state for the indicated STA is State 2, State 3, or State 4, the MLME shall generate a Deauthentication frame to be transmitted to the indicated STA.

NOTE—As the Deauthentication frame is a bufferable MMPDU, the transmission of this frame might be delayed by the operation of a power-saving protocol. The AID and the PTKSA are maintained (when applicable) until the frame is acknowledged or attempts to transmit the frame are abandoned.

- c) The state for the indicated STA shall be set to State 1.

- d) Once the Deauthentication frame is acknowledged or attempts to transmit the frame are abandoned, the MLME shall issue an MLME-DEAUTHENTICATE.confirm primitive to inform the SME of the deauthentication.
- e) The SME, upon receipt of an MLME-DEAUTHENTICATE.confirm primitive, shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the indicated STA by using the MLME-DELETEKEYS.request primitive (see 12.6.18) and by generating an MLME-SETPROTECTION.request(None) primitive.
- f) If the STA is contained within an AP, its SME, upon receipt of an MLME-DEAUTHENTICATE.confirm primitive, shall release the AID assigned for the indicated STA, if the state for the indicated STA was State 3 or State 4.
- g) If the STA is contained within an AP, its SME shall inform the DS of the disassociation, if the state for the indicated STA was State 3 or State 4.
- h) If the STA is a mesh STA, its SME shall inform the mesh peering instance controller (see 14.3.4) of the deauthentication.

11.3.4.5 Deauthentication—destination STA

A DMG STA in State 2, State 3 or State 4 that receives a Deauthentication frame shall remain in the same state if it did not perform an IEEE 802.11 authentication exchange.

Otherwise, upon receipt of a Deauthentication frame from a STA for which the state is State 2, State 3, or State 4, the destination STA shall deauthenticate with the originating STA using the following procedure:

- a) If management frame protection was not negotiated when the PTKSA(s) were created, or if management frame protection is in use and the frame is not discarded per management frame protection processing, the MLME shall issue an MLME-DEAUTHENTICATE.indication primitive to inform the SME of the deauthentication, and set the state for the originating STA to State 1.
- b) Upon receiving an MLME-DEAUTHENTICATE.indication primitive, the SME shall
 - 1) Delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the originating STA by using the MLME-DELETEKEYS.request primitive (see 12.6.18) and by generating an MLME-SETPROTECTION.request(None) primitive.
 - 2) If the STA is contained within an AP, release the AID assigned for the indicated STA and shall inform the DS of the disassociation, if the state for the originating STA was State 3 or State 4.
 - 3) If the STA is a mesh STA, inform the mesh peering instance controller (see 14.3.4) of the deauthentication.

11.3.5 Association, reassociation, and disassociation

11.3.5.1 General

Subclause 11.3.5 describes the procedures used for IEEE 802.11 association, reassociation and disassociation.

The states used in this description are defined in 11.3.1.

Successful association enables a STA to exchange Class 3 frames. Successful association sets the STA's state to State 3 or State 4.

Successful reassociation enables a STA to exchange Class 3 frames. Unsuccessful reassociation when not in State 1 leaves the STA's state unchanged (with respect to the AP or PCP that was sent the Reassociation Request (which may be the current STA)). Successful reassociation sets the STA's state to State 3 or State 4 (with respect to the AP or PCP that was sent the Reassociation Request). Successful reassociation when not

in State 1 sets the STA's state to State 2 (with respect to the current AP or PCP, if this is not the AP or PCP that was sent the Reassociation Request). Reassociation shall be performed only if the originating STA is already associated in the same ESS.

Disassociation notification when not in State 1 sets the STA's state to State 2. The STA shall become associated again prior to sending Class 3 frames. A STA may disassociate a peer STA at any time, for any reason.

If non-DMG STA A in an infrastructure BSS receives a Class 3 frame from STA B that is authenticated but not associated with STA A (i.e., the state for STA B is State 2), STA A shall discard the frame. If the frame has an individual address in the Address 1 field, the MLME of STA A shall send a Disassociation frame to STA B.

If DMG STA A in an infrastructure BSS receives a Class 3 frame from STA B that is not associated with STA A (i.e., the state for STA B is State 2), STA A shall discard the frame. If the frame has an individual address in the Address 1 field, the MLME of STA A shall send a Disassociation frame to STA B.

If an MM-SME coordinated STA receives an Association Response frame with a result code equal to SUCCESS and with the value of the Single AID field within MMS element equal to 1, then

- For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is true, the state is set to State 3. Progress from State 3 to State 4 occurs independently in each such MAC entity.
- For each of its MAC entities advertised within the MMS element and for which dot11RSNAActivated is false, the state is set to State 4.

If the MM-SME coordinated STA in State 3 is assigned an AID for only the MAC entity identified by the RA field of the Association Response with result code equal to SUCCESS, the MM-SME may repeat the association procedure for any other MAC entity coordinated by the MM-SME.

Association is not applicable in an IBSS. In an infrastructure BSS, association is required. In a PBSS, association is optional. APs do not initiate association.

11.3.5.2 Non-AP and non-PCP STA association initiation procedures

The SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the AP or PCP by using MLME-DELETEKEYS.request primitive (see 12.6.18) before invoking MLME-ASSOCIATE.request primitive.

If dot11InterworkingServiceActivated is true, the STA does not have credentials for the AP, and the STA is initiating an emergency services association procedure, the SME shall submit the MLME-ASSOCIATE.request primitive with EmergencyServices parameter set to true.

The MM-SME of a non-AP and non-PCP STA may include an MMS element in an MLME-ASSOCIATE.request primitive. The MM-SME shall include in the MMS element the MAC address associated with the MLME SAP instance to which the primitive is submitted.

Upon receipt of an MLME-ASSOCIATE.request primitive that is part of an on-channel tunneling (see 11.33.4), a non-AP and non-PCP STA shall follow the rules in 11.33.4 in addition to the association procedures described below.

Upon receipt of an MLME-ASSOCIATE.request primitive, a non-AP and non-PCP STA shall associate with an AP or PCP using the following procedure:

- a) If the state for the AP is State 1, the MLME shall inform the SME of the failure of the association by issuing an MLME-ASSOCIATE.confirm primitive, and this procedure ends.
- b) The MLME shall transmit an Association Request frame to the AP or PCP. If the MLME-ASSOCIATE.request primitive contained an RSNE with only one pairwise cipher suite and only one authenticated key suite, this RSNE shall be included in the Association Request frame. If the MLME-ASSOCIATE.request primitive contained the EmergencyServices parameter equal to true, an Interworking element with the UESA field set to 1 shall be included in the Association Request frame.
- c) If an Association Response frame is received with a status code of SUCCESS, a DMG STA shall write to each of the following MIB attributes the value of the corresponding subfield of the DMG BSS Parameter Configuration field of the DMG Operation element received from the AP or PCP to which it requested association:
 - 1) dot11PSRequestSuspensionInterval from the PSRequestSuspensionInterval subfield
 - 2) dot11MinBHIDuration from the MinBHIDuration subfield
 - 3) dot11BroadcastSTAInfoDuration from the BroadcastSTAInfoDuration subfield
 - 4) dot11AssocRespConfirmTime from the AssocRespConfirmTime subfield
 - 5) dot11MinPPDuration from the MinPPDuration subfield
 - 6) dot11SPIdleTimeout from the SPIdleTimeout subfield
 - 7) dot11MaxLostBeacons from the MaxLostBeacons subfield
- d) If an Association Response frame is received with a status code of SUCCESS, the state for the AP or PCP shall be set to State 4 or, if dot11RSNAActivated is true, State 3. The state for any other AP or PCP which is State 3 or State 4 prior to the association request shall be set to State 2, and the MLME shall issue an MLME-ASSOCIATE.confirm primitive to inform the SME of the successful completion of the association.
- e) An MM-SME coordinated STA that receives an Association Response frame with a status code of SUCCESS containing an MLME element with the Single AID field equal to 1, all of the STAs coordinated by the MM-SME are associated with the AP or PCP (i.e., shall be set to State 4 or, if dot11RSNAActivated is true, State 3).
- f) If an Association Response frame is received with a status code other than SUCCESS or the association fails to complete within dot11AssociationResponseTimeout the state for the AP or PCP shall be set to State 2, and the MLME shall issue an MLME-ASSOCIATE.confirm primitive to inform the SME of the failure of the association. The status code returned in the Association Response frame indicates the cause of the failed association attempt. Any misconfiguration or parameter mismatch, e.g., data rates required as basic rates that the STA did not indicate as supported in the STA's Supported Rates and BSS Membership Selectors element, shall be corrected before the SME issues an MLME-ASSOCIATE.request primitive for the same AP or PCP. If the status code indicates the association failed because of a reason that is not related to configuration (e.g., the AP or PCP is unable to support additional associations) and the Association Response frame does not include a Timeout Interval element with Timeout Interval Type equal to 3 the SME shall not issue an MLME-ASSOCIATE.request primitive for the same AP or PCP until a period of at least 2 s has elapsed. If the status code indicates the association failed and the Association Response frame contains a Timeout Interval element with Timeout Interval Type equal to 3, the SME shall not issue an MLME-ASSOCIATE.request primitive for the same AP or PCP until the period specified in the Timeout Interval element has elapsed.
- g) If an MLME-ASSOCIATE.confirm primitive is received with a ResultCode of SUCCESS, and RSNA is required, then the SME shall perform a 4-way handshake to establish an RSNA. As a part of a successful 4-way handshake, the SME enables protection by generating an MLME-SETPROTECTION.request(Rx_Tx) primitive.
- h) Upon receipt of the MLME-SETPROTECTION.request(Rx_Tx) primitive, the MLME shall set the state of the STA to State 4.

11.3.5.3 AP or PCP association receipt procedures

Upon receipt of an Association Request frame from a STA the AP or PCP shall use the following procedure:

- a) The MLME shall issue an MLME-ASSOCIATE.indication primitive to inform the SME of the association request. The SME shall issue an MLME-ASSOCIATE.response primitive addressed to the STA identified by the PeerSTAAddress parameter of the MLME-ASSOCIATE.indication primitive. If the association is not successful, the SME shall indicate a specific reason for the failure to associate in the ResultCode parameter. Upon receipt of the MLME-ASSOCIATE.response primitive, the MLME shall transmit an Association Response frame.
- b) If the state for the STA is 1 and the STA is a non-DMG STA, the SME shall refuse the association request by issuing an MLME-ASSOCIATE.response primitive with ResultCode NOT_AUTHENTICATED.
- c) AP with dot11InterworkingServiceActivated true only: If the MLME-ASSOCIATE.indication primitive has the EmergencyServices parameter set to true and the RSN parameter does not include an RSNE, the SME shall not reject the association request on the basis that dot11RSNAActivated is true, thereby granting access, using unprotected frames (see 9.2.4.1.9), to the network for emergency services purposes.
- d) Otherwise, in an RSNA the SME shall check the values received in the RSN parameter to see whether the values received match the security policy. If they do not, the SME shall refuse the association by issuing an MLME-ASSOCIATE.response primitive with a ResultCode indicating the security policy mismatch.
- e) Otherwise, if the state for the STA is 4, the STA has a valid security association, the STA has negotiated management frame protection, and there has been no earlier, timed out SA Query procedure with the STA (which would have allowed a new association process to be started, without an additional SA Query procedure):
 - 1) The SME shall refuse the association request by issuing an MLME-ASSOCIATE.response primitive with ResultCode REFUSED_TEMPORARILY and TimeoutInterval containing a Timeout Interval element with the Timeout Interval Type field set to 3 (Association Comeback time). If the SME is in an ongoing SA Query with the STA, the Timeout Interval Value field shall be set to the remaining SA Query period, otherwise it shall be set to dot11AssociationSAQueryMaximumTimeout.
 - 2) The state for the STA shall be left unchanged.
 - 3) Following this, if the SME is not in an ongoing SA Query with the STA, the SME shall issue one MLME-SA-QUERY.request primitive addressed to the STA every dot11AssociationSAQueryRetryTimeout TUs until an MLME-SA-QUERY.confirm primitive for the STA is received or dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure have passed. The SME shall increment the TransactionIdentifier by 1 for each MLME-SA-QUERY.request primitive, rolling it over the value to 0 after the maximum allowed value is reached.
 - 4) If no MLME-SA-QUERY.confirm primitive for the STA is received within the dot11AssociationSAQueryMaximumTimeout period, the SME shall allow a subsequent association process with the STA to be started without starting an additional SA Query procedure, except that the SME may deny a subsequent association process with the STA if an MSDU was received from the STA within this period.
- f) NOTE—Reception of an MSDU implies reception of a valid protected frame, which obviates the need for the SA Query procedure.
- f) The SME shall refuse an association request from a STA that does not support all of the rates in the BSSBasicRateSet parameter in the MLME-START.request primitive.

- g) The SME shall refuse an association request from an HT STA that does not support all of the MCSs in the Basic HT-MCS Set field of the HT Operation parameter in the MLME-START.request primitive.
- h) The SME shall refuse an association request from a VHT STA that does not support all of the <VHT-MCS, NSS> tuples indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter in the MLME-START.request primitive.
- i) The SME shall generate an MLME-ASSOCIATE.response primitive with the PeerSTAAddress parameter set to the MAC address of the STA identified by the PeerSTAAddress parameter of the MLME-ASSOCIATE.indication primitive. If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS, the SME has an existing SA with the STA, and an SA Query procedure with that STA has failed to receive a valid response (i.e., has not received an MLME-SA-QUERY.confirm primitive within the dot11AssociationSAQueryMaximumTimeout period), the SME shall issue an MLME-DISASSOCIATE.request primitive addressed to the STA with ReasonCode INVALID_AUTHENTICATION.

NOTE—This MLME-DISASSOCIATE.request primitive generates a protected Disassociation frame. If the association request was genuine, the STA has deleted the PTKSA by this point and so the protected Disassociation frame is ignored. The purpose is to inform a STA which has for some reason failed to respond to an SA Query procedure triggered by a forged association request.

- j) If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 11.5.18 (RSNA security association termination)).
- k) If the MLME-ASSOCIATE.indication primitive includes an MMS parameter, the AP or PCP shall generate the MLME-ASSOCIATE.response primitive directed to the MLME of the STA identified by the PeerSTAAddress parameter of the MLME-ASSOCIATE.request primitive and take the following additional action, as appropriate:
 - l) If the Single AID field in the MMS parameter of the MLME-ASSOCIATE.indication primitive is equal to 1, the AP or PCP may allocate a single AID for all of the STAs included in the MMS element. If the AP or PCP allocates the same AID to each STA whose MAC address was included in the MMS element, it shall include the MMS element received from the MM-SME coordinated STA in the MLME-ASSOCIATION.response primitive.
 - 2) If the Single AID field is 0, the AP or PCP shall allocate a distinct AID for each STA specified in the MMS element.
- l) If an Association Response frame with a status code of SUCCESS is acknowledged by the STA, the state for the STA shall be set to State 4 or, if dot11RSNAActivated is true, State 3.
- m) If the ResultCode in the MLME-ASSOCIATE.response primitive is not SUCCESS and management frame protection is in use the state for the STA shall be left unchanged. If the ResultCode is not SUCCESS and management frame protection is not in use the state for the STA shall be set to State 3 if it was State 4.
- n) If the ResultCode in the MLME-ASSOCIATE.response primitive is SUCCESS and RSNA establishment is required, the SME shall attempt a 4-way handshake. Upon a successful completion of a 4-way handshake, the SME shall enable protection by issuing an MLME-SETPROTECTION.request(Rx_Tx) primitive and the state for the STA shall be set to State 4.
- o) AP only: The SME shall inform the DS of any changes in the state of the STA.

11.3.5.4 Non-AP and non-PCP STA reassociation initiation procedures

Except when the association is part of a fast BSS transition, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the AP or PCP by using the MLME-DELETEKEYS.request primitive (see 12.6.18) before invoking an MLME-REASSOCIATE.request primitive.

If `dot11InterworkingServiceActivated` is true and the STA was associated to the ESS for unsecured access to emergency services, the SME shall submit the `MLME-REASSOCIATE.request` primitive with `EmergencyServices` parameter set to true.

The MM-SME of a non-AP and non-PCP STA may include an MMS element in an `MLME-REASSOCIATE.request` primitive. The MM-SME shall include in the MMS element the MAC address associated with the MLME SAP instance to which the primitive is submitted.

Upon receipt of an `MLME-REASSOCIATE.request` primitive that is part of an on-channel tunneling (see 11.33.4), a non-AP and non-PCP STA shall follow the rules in 11.33.4 in addition to the reassociation procedures described below.

Upon receipt of an `MLME-REASSOCIATE.request` primitive, a non-AP and non-PCP STA shall reassociate with an AP or PCP using the following procedure:

- a) If the STA is not associated in the same ESS or the state for the new AP is State 1, the MLME shall inform the SME of the failure of the reassociation by issuing an `MLME-REASSOCIATE.confirm` primitive, and this procedure ends.
- b) The MLME shall transmit a Reassociation Request frame to the new AP or PCP. If the `MLME-REASSOCIATE.request` primitive contained an RSNE with only one pairwise cipher suite and only one authenticated key suite, this RSNE shall be included in the Reassociation Request frame. If the `MLME-REASSOCIATE.request` primitive contained the `EmergencyServices` parameter equal to true, an Interworking element with the UESA field set to 1 shall be included in the Reassociation Request frame.
- c) If a Reassociation Response frame is received with a status code of `SUCCESS`, the state variable for the new AP or PCP shall be set to State 4 or to State 3 if `dot11RSNAActivated` is true and the FT protocol is not used with respect to the new AP or PCP and, unless the old AP or PCP and new AP or PCP are the same, to State 2 with respect to the old AP or PCP, and the MLME shall issue an `MLME-REASSOCIATE.confirm` primitive to inform the SME of the successful completion of the reassociation.

If the `MLME-REASSOCIATION.request` primitive has the new AP's MAC address in the `CurrentAPAddress` parameter (reassociation to the same AP), the following states, agreements and allocations shall be deleted or reset to initial values:

- 1) All EDCAF state
- 2) Any block ack agreements
- 3) Sequence number
- 4) Packet number
- 5) Duplicate detection caches
- 6) Anything queued for transmission
- 7) Fragmentation and reassembly buffers
- 8) Power management mode
- 9) WNM sleep mode
- 10) SMKSAs, STKSAs and TPKSAs established with any peers.

The following states, agreements and allocations are not affected by the reassociation procedure:

- 1) PSMP sessions
- 2) Enablement/Deenablement
- 3) GDD enablement
- 4) STSL, DLS and TDLS agreements
- 5) MMSLs

- 6) GCR agreements
 - 7) DMS agreements
 - 8) TFS agreements
 - 9) FMS agreements
 - 10) Triggered autonomous reporting agreements
 - 11) FTM sessions
 - 12) DMG SP and CBAP allocations.
- d) If a Reassociation Response frame is received with a status code of SUCCESS, a DMG STA shall write to each of the following MIB attributes the value of the corresponding subfield of the DMG BSS Parameter Configuration field of the DMG Operation element received from the AP or PCP to which it requested reassociation:
- 1) dot11PSRequestSuspensionInterval from the PSRequestSuspensionInterval subfield
 - 2) dot11MinBHIDuration from the MinBHIDuration subfield
 - 3) dot11BroadcastSTAInfoDuration from the BroadcastSTAInfoDuration subfield
 - 4) dot11AssocRespConfirmTime from the AssocRespConfirmTime subfield
 - 5) dot11MinPPDuration from the MinPPDuration subfield
 - 6) dot11SPIidleTimeout from the SPIidleTimeout subfield
 - 7) dot11MaxLostBeacons from the MaxLostBeacons subfield
- e) An MM-SME coordinated STA that receives a Reassociation Response frame with a status code of SUCCESS containing an MLME element with the Single AID field equal to 1, all of the STAs coordinated by the MM-SME are reassociated with the AP or PCP (i.e., shall be set to State 4 or, if dot11RSNAActivated is true, State 3).
- f) If a Reassociation Response frame is received with a status code other than SUCCESS or the reassociation fails to complete within dot11AssociationResponseTimeout:
- 1) Except when the association is part of a fast BSS transition, the state for the AP or PCP shall be set to State 2 with respect to the new AP or PCP.
 - 2) The MLME shall issue an MLME-REASSOCIATE.confirm primitive to inform the SME of the failure of the reassociation. The ResultCode returned in the MLME-REASSOCIATE.confirm primitive indicates the cause of the failed reassociation attempt. Any misconfiguration or parameter mismatch, e.g., data rates required as basic rates that the STA did not indicate as supported in the STA's Supported Rates and BSS Membership Selectors element, shall be corrected before the SME issues an MLME-REASSOCIATE.request primitive for the same AP or PCP. If the status code indicates the reassociation failed because of a reason that is not related to configuration (e.g., the AP or PCP is unable to support additional associations) and the Reassociation Response frame does not include a Timeout Interval element with Timeout Interval Type equal to 3 the SME shall not issue an MLME-REASSOCIATE.request primitive for the same AP or PCP until a period of at least 2 s has elapsed. If the status code indicates the reassociation failed and the Reassociation Response frame contains a Timeout Interval element with Timeout Interval Type equal to 3, the SME shall not issue an MLME-REASSOCIATE.request primitive for the same AP or PCP until the period specified in the Timeout Interval element has elapsed.
- g) If an MLME-REASSOCIATE.confirm primitive is received with a ResultCode of SUCCESS, and RSNA is required, and the STA is in State 3, then the SME shall perform a 4-way handshake to establish an RSNA. As a part of a successful 4-way handshake, the SME shall enable protection by generation an MLME-SETPROTECTION.request(Rx_Tx) primitive
- h) Upon receipt of the MLME-SETPROTECTION.request(Rx_Tx), the MLME shall set the state of the STA to State 4.

11.3.5.5 AP or PCP reassociation receipt procedures

Upon receipt of a Reassociation Request frame from a STA the AP or PCP shall use the following procedure:

- a) The MLME shall issue an MLME-REASSOCIATE.indication primitive to inform the SME of the reassociation request. The SME shall issue an MLME-REASSOCIATE.response primitive addressed to the STA identified by the PeerSTAAddress parameter of the MLME-REASSOCIATE.indication primitive. If the reassociation is not successful, the SME shall indicate a specific reason for the failure to reassociate in the ResultCode parameter. Upon receipt of the MLME-REASSOCIATE.response primitive, the MLME shall transmit a Reassociation Response frame.
- b) If the state for the STA is 1 and the STA is a non-DMG STA, the SME shall refuse the reassociation request by issuing an MLME REASSOCIATE.response primitive with ResultCode NOT_AUTHENTICATED.
- c) AP with dot11InterworkingServiceActivated true only: If the MLME-REASSOCIATE.indication primitive has the EmergencyServices parameter set to true and the RSN parameter does not include an RSNE, the SME shall not reject the reassociation request on the basis that dot11RSNAActivated is true and dot11PrivacyInvoked is true thereby granting access, using unprotected frames (see 9.2.4.1.9), to the network for emergency services purposes.
- d) Otherwise, in an RSNA the SME shall check the values received in the RSN parameter to see whether the values received match the security policy. If they do not, SME shall refuse the reassociation by issuing an MLME-REASSOCIATE.response primitive with a ResultCode indicating the security policy mismatch.
- e) Otherwise, if the state for the STA is 4, the STA has a valid security association, the STA has negotiated management frame protection, the reassociation is not a part of a fast BSS transition, and there has been no earlier, timed out SA Query procedure with the STA (which would have allowed a new reassociation process to be started, without an additional SA Query procedure):
 - 1) The SME shall refuse the reassociation request by issuing an MLME-REASSOCIATE.response primitive with ResultCode REFUSED_TEMPORARILY and TimeoutInterval containing a Timeout Interval element with the Timeout Interval Type field set to 3 (Association Comeback time). If the SME is in an ongoing SA Query with the STA, the Timeout Interval Value field shall be set to the remaining SA Query period, otherwise it shall be set to dot11AssociationSAQueryMaximumTimeout.
 - 2) The state for the STA shall be left unchanged.
 - 3) Following this, if the SME is not in an ongoing SA Query with the STA, the SME shall issue one MLME-SA-QUERY.request primitive addressed to the STA every dot11AssociationSAQueryRetryTimeout TUs until an MLME-SA-QUERY.confirm primitive for the STA is received or dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure have passed. The SME shall increment the TransactionIdentifier by 1 for each MLME-SA-QUERY.request primitive, rolling it over to 0 after the maximum allowed value is reached.
 - 4) If no MLME-SA-QUERY.confirm primitive for a STA is received within the dot11AssociationSAQueryMaximumTimeout period, the SME shall allow a subsequent reassociation process to be started without starting an additional SA Query procedure, except that the SME may deny a subsequent reassociation process with the STA if an MSDU was received from the STA within this period.
- f) NOTE—Reception of an MSDU implies reception of a valid protected frame, which obviates the need for the SA Query procedure.
- f) The SME shall refuse a reassociation request from a STA that does not support all the rates in the BSSBasicRateSet parameter in the MLME-START.request primitive.

- g) The SME shall refuse a reassociation request from an HT STA that does not support all of the MCSs in the Basic HT-MCS Set field of the HT Operation parameter in the MLME-START.request primitive.
- h) The SME shall refuse a reassociation request from a VHT STA that does not support all of the <VHT-MCS, NSS> tuples indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter in the MLME-START.request primitive.
- i) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS, the SME has an existing SA with the STA, and an SA Query procedure with that STA has failed to receive a valid response (i.e., has not received an MLME-SA-QUERY.confirm primitive within the dot11AssociationSAQueryMaximumTimeout period), the SME shall issue an MLME-DISASSOCIATE.request primitive addressed to the STA with ReasonCode INVALID_AUTHENTICATION.

NOTE—This MLME-DISASSOCIATE.request primitive generates a protected Disassociation frame. If the reassociation request was genuine, the STA has deleted the PTKSA by this point and so the protected Disassociation frame is ignored. The purpose is to inform a STA which has for some reason failed to respond to an SA Query procedure triggered by a forged reassociation request.

- j) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS and the reassociation is not part of a fast BSS transition, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 11.5.18 (RSNA security association termination)).
- k) If the MLME-REASSOCIATE.indication primitive includes an MMS parameter, the AP or PCP shall take the following additional action, as appropriate:
 - 1) If the Single AID field in the MMS parameter of the MLME-REASSOCIATE.indication primitive is equal to 1, the AP or PCP may allocate a single AID for all of the STAs included in the MMS element. If the AP or PCP allocates the same AID to all STAs whose MAC address was included in the MMS element, it shall include the MMS element received from the MM-SME coordinated STA in the MLME-REASSOCIATE.response primitive.
 - 2) If the Single AID field is 0, the AP or PCP shall allocate a distinct AID for each STA specified in the MMS element.
- l) If a Reassociation Response frame with a status code of SUCCESS is acknowledged by the STA, the state for the STA shall be set to State 4, or to State 3 if dot11RSNAAactivated is true and the reassociation is not part of a fast BSS transition.
- m) If the ResultCode in the MLME-REASSOCIATE.response primitive is not SUCCESS and management frame protection is in use the state for the STA shall be left unchanged. If the ResultCode is not SUCCESS, management frame protection is not in use, and the reassociation is part of a fast BSS transition, the state for the STA shall be left unchanged. If the ResultCode is not SUCCESS, management frame protection is not in use, and the reassociation is not part of a fast BSS transition, the state for the STA shall be set to State 3 if it was State 4.
- n) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS, RSNA establishment is required, and the reassociation is not part of a fast BSS transition, the SME shall attempt a 4-way handshake. Upon a successful completion of a 4-way handshake, the SME shall enable protection by issuing an MLME-SETPROTECTION.request(Rx_Tx) primitive and the state for the STA shall be set to State 4.
- o) AP only: The SME shall inform the DS of any changes in the state of the STA.
- p) If the ResultCode in the MLME-REASSOCIATE.response primitive is SUCCESS and the CurrentAPAddress parameter in the MLME-REASSOCIATION.indication primitive had the new AP's MAC address in the CurrentAPAddress parameter (reassociation to the same AP), the AP shall match the non-AP STAs treatment of the listed agreements and allocations as described in 11.3.5.4 list item c). The AP deletes or resets to initial values those items that the non-AP STA is required in

11.3.5.4 list item c) to delete or reset to initial values, and the AP does not modify the states, agreements and allocations that are listed as not affected by the reassociation procedure.

11.3.5.6 Non-AP and non-PCP STA disassociation initiation procedures

The SME shall issue an MLME-DISASSOCIATE.request primitive that includes an appropriate Reason Code as defined in Table 9-45 of 9.4.1.7.

Upon receipt of an MLME-DISASSOCIATE.request primitive, a non-AP and non-PCP STA's MLME shall disassociate from an AP or PCP using the following procedure:

- a) If the state for the AP or PCP is State 3 or State 4, the MLME shall transmit a Disassociation frame to the AP or PCP.
- b) The state for the AP or PCP shall be set to State 2 if it was not State 1. In the case of an MM-SME coordinated STA, the MLME shall perform this for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
- c) The MLME shall issue an MLME-DISASSOCIATE.confirm primitive to inform the SME of the successful completion of the disassociation.
- d) Upon receiving an MLME-DISASSOCIATE.confirm primitive, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the AP or PCP by using the MLME-DELETEKEYS.request primitive (see 12.6.18) and by invoking an MLME-SETPROTECTION.request(None) primitive. In the case of an MM-SME coordinated STA, the MLME shall perform this for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.

11.3.5.7 Non-AP and non-PCP STA disassociation receipt procedure

Upon receipt of a Disassociation frame from an AP or PCP for which the state is State 3 or State 4, if management frame protection was not negotiated when the PTKSA(s) were created, or if management frame protection is in use and the frame is not discarded per management frame protection processing, a non-AP and non-PCP STA shall disassociate from the AP or PCP using the following procedure:

- a) The state for the AP or PCP shall be set to State 2.
- b) The MLME shall issue an MLME-DISASSOCIATE.indication primitive to inform the SME of the disassociation.
- c) Upon receiving the MLME-DISASSOCIATE.indication primitive, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the AP or PCP by using the MLME-DELETEKEYS.request primitive (see 12.6.18) and by invoking an MLME-SETPROTECTION.request(None) primitive. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
- d) If the reason code indicates a configuration or parameter mismatch as the cause of the disassociation, the SME shall not attempt to associate or reassociate with the AP or PCP until the configuration or parameter mismatch has been corrected.
- e) If the reason code indicates the STA was disassociated for a reason other than configuration or parameter mismatch, the SME shall not attempt to associate or reassociate with the AP or PCP until a period of 2 s has elapsed.

11.3.5.8 AP or PCP disassociation initiation procedure

The SME shall issue an MLME-DISASSOCIATE.request primitive that includes an appropriate Reason Code as defined Table 9-45 of 9.4.1.7.

Upon receipt of an MLME-DISASSOCIATE.request primitive, an AP or PCP shall disassociate a STA using the following procedure:

- a) If the state for the STA is State 3 or State 4, the AP or PCP shall generate a Disassociation frame to be transmitted to the indicated STA.

NOTE—As the Disassociation frame is a bufferable MMPDU, the transmission of this frame might be delayed by the operation of a power-saving protocol. The AID and the PTKSA are maintained (when applicable) until the frame is acknowledged or attempts to transmit the frame are abandoned.
- b) The state for the STA shall be set to State 2, if it was not State 1. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
- c) Once the Disassociation frame is acknowledged or attempts to transmit the frame are abandoned, the MLME shall issue an MLME-DISASSOCIATE.confirm primitive to inform the SME of the disassociation.
- d) Upon receiving an MLME-DISASSOCIATE.confirm primitive, the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 12.6.18) and by invoking an MLME-SETPROTECTION.request(None) primitive. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
- e) Upon receiving an MLME-DISASSOCIATE.confirm primitive, the SME shall release the AID assigned for the indicated STA, if the state for the indicated STA was State 3 or State 4.
- f) AP only: The SME shall inform the DS of the disassociation.

11.3.5.9 AP or PCP disassociation receipt procedure

Upon receipt of a Disassociation frame from a STA for which the state is State 3 or State 4, if management frame protection was not negotiated when the PTKSA(s) were created, or if management frame protection is in use and the frame is not discarded per management frame protection processing, the AP or PCP shall disassociate the STA using the following procedure:

- a) The state for the STA shall be set to State 2. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
- b) The MLME shall issue an MLME-DISASSOCIATE.indication primitive to inform the SME of the disassociation.
- c) Upon receiving an MLME-DISASSOCIATE.indication primitive the SME shall delete any PTKSA, GTKSA, IGTKSA and temporal keys held for communication with the STA by using the MLME-DELETEKEYS.request primitive (see 12.6.18) and by invoking an MLME-SETPROTECTION.request(None) primitive. The MM-SME shall perform this process for each STA whose address was included in the MMS parameter of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive that established the association.
- d) AP only: The SME shall inform the DS of the disassociation.
- e) The SME shall release the AID assigned for the indicated STA.

11.3.5.10 PBSS procedures for nonassociated STAs

In a PBSS, there are four types of relationships between a PCP and the members of a PBSS:

- Nonassociated, non-RSNA (when dot11RSNAAActivated is false)
- Associated, non-RSNA (when dot11RSNAAActivated is false)
- Associated, RSNA (when dot11RSNAAActivated is true)
- Nonassociated, RSNA (when dot11RSNAAActivated is true)

The following rules apply in the last case:

- a) In a PBSS, when a STA is in State 2 and dot11RSNAAActivated is true, successful RSNA establishment changes the STA to State 4. Unsuccessful RSNA establishment leaves the state unchanged.
- b) In a PBSS, when a STA is in State 4, the STA's receipt of a disassociation notification changes the state to State 2.

11.3.6 Additional mechanisms for an AP collocated with a mesh STA

If a STA to AP mapping is added to the DS with the STA being a non-AP STA in an infrastructure BSS and the AP being an access point that interconnects through a DS with a mesh gate (that is, AP and mesh gate are collocated; see Figure 4-10), this mesh gate shall verify that the MAC address of the STA does not belong to a mesh STA in the MBSS. See 4.5.3.3 and Clause 7 for association and STA to AP mapping in the DS. If the mesh gate determines that the authenticated STA has a MAC address that is a MAC address of a mesh STA in the MBSS, then the collocated access point shall deauthenticate the STA with Reason Code UNSPECIFIED_REASON or MACADDRESS-ALREADY-EXISTS-IN-MBSS.

The mechanism for verifying the MAC address of the authenticated STA depends on the active path selection protocol and might be vendor specific. See 14.10.13 when HWMP is the active path selection protocol.

11.3.7 Communicating PBSS information

Following the association or security association of a STA with a PCP, the PCP shall send an unsolicited Information Response frame (9.6.20.5 to all STAs associated with the PCP. The PCP shall send a broadcast Information Response frame and/or shall send individually addressed Information Response frames to each STA associated with the PCP. The PCP shall set the Subject Address field of the Information Response frame to the broadcast address and shall include in the Information Response frame the DMG Capabilities element for the PCP and each STA associated with the PCP. This process is referred to as *PBSS information distribution*.

The PCP shall perform a PBSS information distribution at least once every dot11BroadcastSTAInfoDuration beacon intervals.

11.3.8 Neighbor report information upon rejection with suggested BSS transition

An AP may provide neighbor report information to a STA that requests authentication or association by responding with an Authentication or (Re)Association Response frame that has the Reason Code field set to REJECTED_WITH_SUGGESTED_BSS_TRANSITION and that includes one or more Neighbor Report elements.

11.4 TS operation

11.4.1 Introduction

There are three types of traffic specifications: the TSPEC, the DMG TSPEC, and the PTP TSPEC.

A TSPEC describes the traffic characteristics and the QoS requirements of a TS. The main purpose of the TSPEC is to reserve resources within the HC and, in the case of HCCA and HEMM access policies, to modify the HC's scheduling behavior. It also allows other parameters to be specified that are associated with the TS, such as a traffic classifier and acknowledgment policy.

The DMG TSPEC (9.4.2.134) describes an allocation (also known as DMG allocation) within either a PBSS or a DMG infrastructure BSS. The purpose of the DMG TSPEC is to create or modify an allocation for the transmission of frames between DMG STAs that are members of a PBSS or that are members of an infrastructure BSS (10.36.6).

To communicate between STAs in a PBSS or between non-AP DMG STAs in an infrastructure BSS, a TSPEC (as defined in 9.4.2.30) is used to create or modify a TS between those STAs. This TSPEC is referred to as a *PTP TSPEC*.

In a DMG BSS, a TSPEC includes parameters that are associated with the TS such as maximum MSDU size, delay bound, and optionally the allocation carrying the TS. A single allocation can carry multiple TSs. Each TS is carried in one allocation, except when

- The TS has an access policy of EDCA, where it can use all CBAP allocations with Source AID equal to the broadcast AID, all CBAP allocations with Source AID matching the source STA of the TS, and all CBAP allocations with Destination AID matching the destination STA of the TS; or
- The TS has an access policy of SEMM, where it can use exactly one SP allocation as well as all CBAP allocations with Source AID equal to the broadcast AID, all CBAP allocations with Source AID matching the source STA of the TS, and all CBAP allocations with Destination AID matching the destination STA of the TS.

A TS may have one or more TCLAS (within the discretion of the STA that sets up the stream) associated with it. A DMG STA or AP uses the parameters in the TCLAS elements to filter the MSDUs belonging to this TS for delivery as part of the TS. An Intra-Access Category Priority element may be associated with a TS by the inclusion of an Intra-Access Category Priority element in an ADDTS Request frame. The User Priority subfield of the Intra-Access Category Priority element shall be set to the same UP as specified in the User Priority subfield of the TS Info field. If `dot11AlternateEDCAActivated` is true, the Alternate Queue subfield is used to select the appropriate EDCA transmit queue when the Access Policy subfield of the TS Info field in the TSPEC is EDCA or HEMM. When an Intra-Access Category Priority element is associated with a TS, the Drop Eligibility subfield is used to indicate the drop eligibility of the MSDUs of this TS.

TS may have zero or one Expedited Bandwidth Request (EBR) element associated with it. An AP uses the parameters in the EBR to understand the precedence level requested by a non-AP STA (see R.5.4). For example, the precedence level may be used to convey to the AP that the requested TS is for the purposes of placing an emergency call. Support for precedence levels greater than 18 is optional for STAs.

TSPEC, PTP TSPEC, optional TCLAS, optional EBR, and optional Intra-Access Category Priority elements are transported over the WM by the ADDTS Request frame and the ADDTS Response frame, and across the MLME SAP by the MLME-ADDS primitives. In addition, a TS could be created if a STA sends a resource request to an AP or PCP prior to initiating a transition to that AP or PCP, as part of performing FST (11.33), or in the Reassociation Request frame to that AP or PCP.

The DMG TSPEC is transported over the air within DMG ADDTS Request and DMG ADDTS Response frames and across the MLME SAP by the MLME-ADDS primitives.

Following a successful negotiation, a TS is created, identified within the non-AP STA by its TSID and direction, and identified within the HC by a combination of TSID, direction, and STA address.

Following a successful negotiation of a DMG TSPEC in a PBSS or in a DMG infrastructure BSS, a new allocation is created, or an existing allocation is modified. Within a PBSS or infrastructure BSS, each allocation is uniquely identified by a combination of allocation ID, source AID, and destination AID.

Following a successful negotiation of a PTP TSPEC or a TSPEC in a DMG BSS, the frames corresponding to the PTP TSPEC or TSPEC are identified within the STA by the combination of TSID, requesting non-AP DMG STA address, and responding non-AP DMG STA address and direction.

It is always the responsibility of the non-AP STA to initiate the creation of a TS regardless of its direction. A STA that is not a DMG STA shall not transmit a PTP TSPEC or a DMG TSPEC. A non-AP DMG STA that is not the source DMG STA of a specific TS shall not initiate the exchange of a TSPEC to the AP DMG STA or PCP DMG STA to create that TS. Any non-AP DMG STA can issue a PTP TSPEC to any other non-AP DMG STA to create a TS.

In the direct-link or TDLS direct-link case, it is the responsibility of the STA that is going to send the data to create the TS. In this case, the STA negotiates with the HC to gain TXOPs that it uses to send the data. There is no negotiation between the originator and recipient STAs concerning the TS: the originator can discover the capabilities of the recipient (rates, Block Ack) using the DLS.

In the case of traffic relayed by an AP or PCP, the sending and receiving non-AP and non-PCP STAs may both create individual TS for the traffic. In an infrastructure BSS, any traffic classifier created for the downlink TS applies equally regardless of whether the source is in the same BSS or reached through the DS.

In a non-DMG infrastructure BSS, a non-AP STA may simultaneously support up to eight TSs from the HC to itself and up to eight TSs from itself to other STAs, including the HC. The actual number it supports may be less due to implementation restrictions.

In a non-DMG infrastructure BSS, an HC may simultaneously support up to eight downlink TSs and up to eight uplink TSs per associated STA. The actual number it supports may be less due to implementation restrictions.

In a DMG BSS there may be up to 16 TSs from a source DMG STA to a destination DMG STA. An additional 16 TSs may be created between the two DMG STAs by reversing the roles of source and destination. The actual number supported in any direction may be less due to implementation restrictions in either the source or destination DMG STA.

In a non-DMG BSS, the traffic admitted in the context of a TSPEC can be sent using EDCA, HCCA, or HEMM. This depends on the access policy set in the TS Info field in the TSPEC. A TSPEC request may be set so that both HCCA and EDCA mechanisms (i.e., HEMM) are used.

In a DMG BSS, the traffic admitted in the context of a PTP TSPEC or TSPEC is sent according to the access policy set in the TS Info field of the PTP TSPEC or TSPEC, respectively. Specifically, the traffic is sent during one or more CBAP allocations if the access policy is EDCA, during an SP allocation if the access policy is SPCA, and during one SP allocation as well as zero or more CBAP allocations if the access policy is SEMM.

A DMG STA transmitting a DMG TSPEC shall set the LP SC Used subfield within the DMG TSPEC to 1 to indicate that the low-power SC mode described in 21.7 is used during the allocation. All frames sent during

such an allocation shall use the low-power SC mode. The STA shall set the LP SC Used subfield to 1 only if the STA identified in the Destination AID field within the DMG TSPEC supports the low-power SC mode (9.4.2.128.2). In all other cases, the LP SC Used subfield shall be set to 0.

When dot11SSPNInterfaceActivated is true, TSPEC processing by the HC may be subject to limitations received from the SSPN interface. The SSPN may limit access to certain QoS priorities, and further restrict the data rate and delay used with any priority.

11.4.2 TSPEC construction

TSPECs and DMG TSPECs are constructed at the SME, from application requirements supplied via the SME, and with information specific to the MAC layer.

The value of the Minimum PHY Rate in a TSPEC shall satisfy the following constraints:

- a) For an uplink TS, it
 - Is included in dot11SupportedDataRatesTxTable and in the AP's operational rate set, or
 - Corresponds to an HT MCS included in dot11SupportedMCSTxTable, if present, and in the AP's operational HT MCS set, if defined, at a bandwidth and guard interval supported by the non-AP STA on transmission and permitted in the BSS, or
 - Corresponds to a VHT-MCS and NSS for which support is indicated by the combination of the Tx VHT-MCS Map subfield in the VHT Operation parameter of the MLME-(RE)ASSOCIATE.request primitive, if present, and the AP's operational VHT-MCS and NSS set, if defined, and the VHT Capabilities Information field, at a bandwidth and guard interval supported by the non-AP STA on transmission and permitted in the BSS.
- b) For a downlink TS, it
 - Is included in the OperationalRateSet parameter of the MLME-JOIN.request primitive and supported by the AP on transmission,⁴³ or
 - Corresponds to an HT MCS included in dot11SupportedMCSRxTable, if present, and supported by the AP on transmission, at a bandwidth and guard interval supported by the non-AP STA on reception and permitted in the BSS,⁴⁴ or
 - Corresponds to a VHT-MCS and NSS for which support is indicated by the Rx VHT-MCS Map subfield in the VHT Operation parameter of the MLME-(RE)ASSOCIATE.request primitive, if present, and the Tx VHT-MCS Map subfield of the VHT Operation element advertised by the AP, if present, and the VHT Capabilities Information field, at a bandwidth and guard interval supported by the non-AP STA on reception and permitted in the BSS.
- c) For a bidirectional TS, it satisfies both a) and b) above.

See K.4 for a description of the parameter choice for the TSPEC.

NOTE—This standard states no requirements on how a DMG TSPEC is to be generated.

11.4.3 TS life cycle

Figure 11-14 summarizes the TS life cycle (using the HMSC syntax defined in ITU-T Recommendation Z.120 (2004)).

⁴³How a non-AP STA determines an AP's non-HT rate transmission support is implementation dependent. The non-AP STA might conservatively use the basic rate set, or it might use knowledge of past transmissions by the AP, or it might use other means.

⁴⁴How a non-AP STA determines an AP's HT MCS transmission support, if the Tx MCS Set subfield in the HT Capabilities element advertised by the AP is equal to 0 or if the Tx Rx MCS Set Not Equal subfield in that element is equal to 1, is implementation dependent. The non-AP STA might conservatively use the basic HT-MCS set, or it might use knowledge of past transmissions by the AP, or it might use other means.

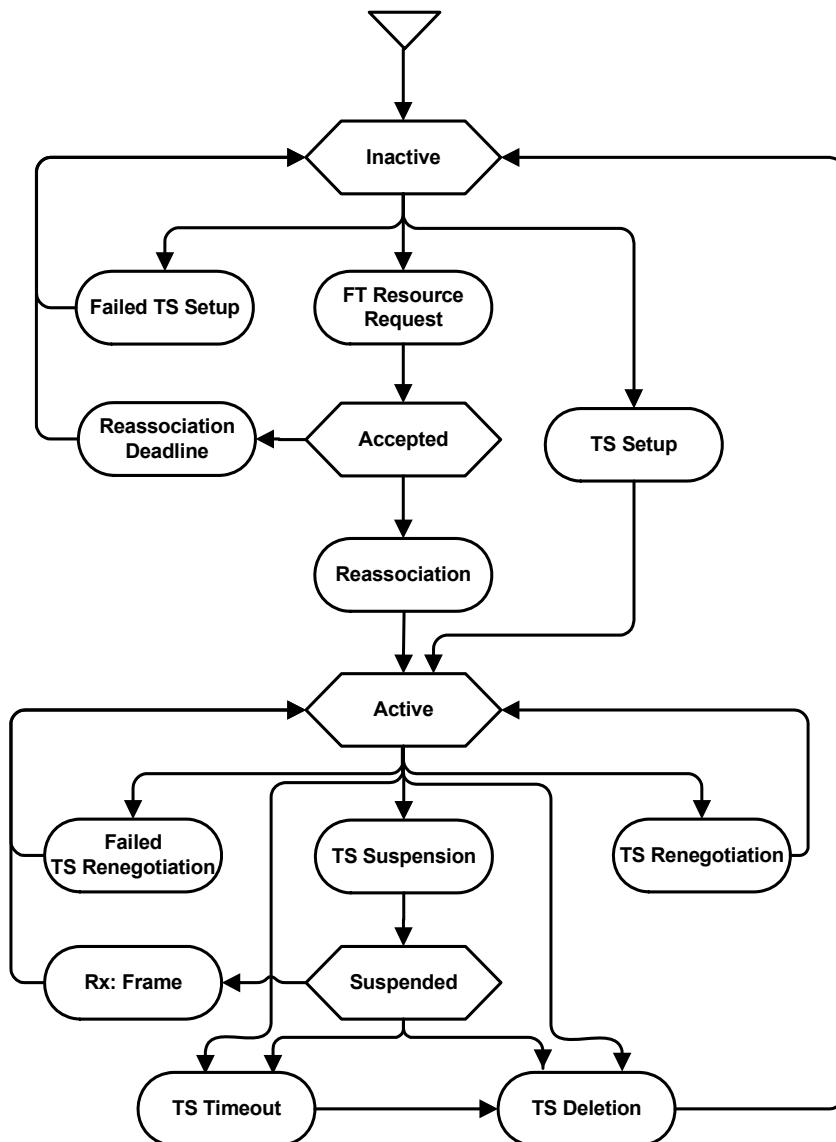

Figure 11-14—TS life cycle

Initially a TS is inactive. A STA shall not transmit any QoS Data frames in which the TID subfield of the QoS Control field matches an inactive TS.

A TS may be established by a Resource Request appearing in a message as part of a fast BSS transition from a STA. Such a TS is created in the accepted state. If the STA subsequently reassociates with this AP, then the TS becomes active. If the STA does not reassociate prior to the expiration of the reassociation timeout, then the TS becomes inactive.

Unless stated otherwise, in a DMG BSS, the owner of an SP is the source DMG STA for that SP, and the owner of a TXOP is the TXOP holder. A STA that owns an SP or a TXOP is said to have the ownership of the SP or the TXOP, respectively. The rules applicable to an SP or TXOP owner are defined in 10.36 and 11.4.

Following a successful TS setup initiated by a non-AP STA, the TS becomes active, and either the non-AP STA or the HC may transmit QoS Data frames whose TID contains this TSID (according to the Direction field). In the case of EDCA, the TID contains the UP value.

While the TS is active, the non-AP STA can attempt to renegotiate the parameters of the TSPEC characterizing the TS or the parameters of the DMG TSPEC characterizing the allocation carrying the TS.

An active TS becomes inactive following a TS deletion process initiated at either non-AP STA or HC. It also becomes inactive following a TS timeout detected at the HC, or if the HC within an AP when dot11SSPNInterfaceActivated is true determines as defined in 11.25.5 that the non-AP STA's TS has exceeded the transmitted MSDU limit for the access category in which the TS was admitted. In a DMG BSS, a TS timeout is detected at a non-AP STA and causes the TS deletion process to be initiated at the non-AP STA. When an active TS becomes inactive, all of the resources allocated for the TS are released.

An active TS may become suspended if no activity is detected for a duration of a suspension interval. Upon detection of activity, the TS may be reinstated. While the TS is in the suspended state, the HC shall not reclaim the resources assigned to the TS. In a DMG BSS, a TS in which both the source and destination are non-AP and non-PCP STAs shall not be suspended.

11.4.4 TS setup

11.4.4.1 General

A TS setup may be initiated by a non-AP STA or an AP.

11.4.4.2 Non-AP-STA-initiated TS setup

Figure 11-15 shows the sequence of messages occurring at a TS setup initiated by a non-AP STA. This message sequence in this figure and in the subsequent figures does not show the acknowledgment.

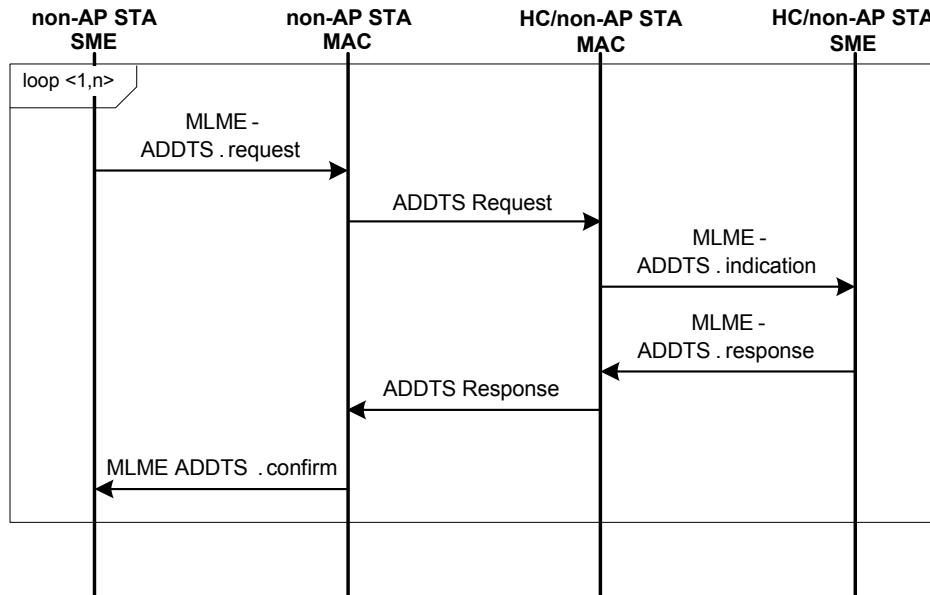

Figure 11-15—TS setup

11.4.4.3 AP-initiated TS setup

Figure 11-16 shows the sequence of messages occurring at a TS setup initiated by the AP. This message sequence in this figure and in the subsequent figures does not show the acknowledgments.

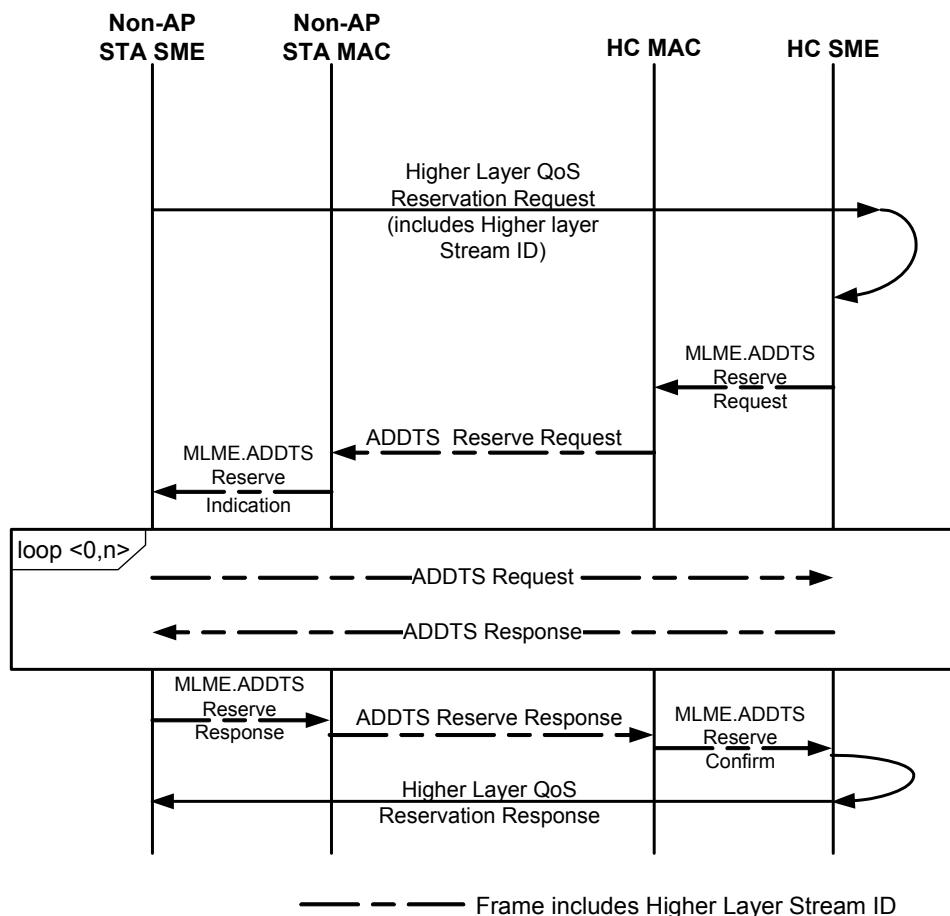

Figure 11-16—TS setup when initiated by the AP

TS setup may be initiated by an AP in response to a request originating from higher layer protocols. An AP in which dot11RobustAVStreamingImplemented is true shall not send ADDTS Reserve Request frames to an associated STA that has set the RobustAVStreaming bit in the Extended Capabilities element in its (Re)Association Request frame to 0.

The higher layer stream ID is defined by the higher layer protocol. The Higher Layer Stream ID element shall be included in the ADDTS Reserve Request frame sent by the AP to the non-AP STA. This Higher Layer Stream ID is used in the TS setup procedure between the AP and the non-AP STA.

The AP initiates the TS setup by sending an ADDTS Reserve Request frame that includes the Higher Layer Stream ID element to the non-AP STA. On receipt of the ADDTS Reserve Request frame from the AP, the non-AP STA shall perform one of the following:

- Complete the AP-initiated TS setup procedure by sending an ADDTS Reserve Response frame that includes the Higher Layer Stream ID corresponding to the AP-initiated TS setup procedure and with the status code set to "SUCCESS."

- b) Send an ADDTS Reserve Response frame with a status code not equal to SUCCESS and abort the AP-initiated TS setup. The Higher Layer Stream ID field in this ADDTS Reserve Response frame shall be set to the Higher Layer Stream ID corresponding to the AP-initiated TS setup procedure.
- c) Send an ADDTS Request frame to the AP. There might be multiple ADDTS Request/ADDTS Response exchanges between the non-AP STA and the AP, as described in 11.4.4.4, to negotiate the TSPEC parameters. The Higher Layer Stream ID shall be included in all frames corresponding to the AP-initiated TS setup procedure that are exchanged between the non-AP STA and the AP. The AP-initiated TS setup procedure is completed by sending an ADDTS Reserve Response frame that includes the Higher Layer Stream ID corresponding to the AP-initiated TS setup procedure and with the status code set to indicate the result of the TSPEC negotiation.

NOTE 1—Stream Reservation Protocol (SRP) as described in Clause 35 of IEEE Std 802.1Q-2011 is an example of a higher layer protocol. The IEEE 802.11 subsystem at a non-AP STA does not interpret the SRP reservation request but simply sends it to the AP with which it is associated. A higher layer agent called *Designated Multiple Stream Registration Protocol (MSRP) Node (DMN)* is co-located with the AP in the device that supports SRP. All incoming SRP reservation requests are forwarded to the MSRP DMN. The MSRP DMN interprets the SRP reservation request and invokes appropriate IEEE 802.11 primitives in order for the AP to invoke the MLME-ADDSRESERVE.request primitive. The MSRP DMN responds to the originator of the SRP Reservation request with the outcome of the AP-initiated TS setup procedure. The procedures performed by the MSRP DMN are described in C.3 of IEEE Std 802.1Q-2011.

NOTE 2—if the higher layer SRP Reservation Request message is lost within the IEEE 802.11 subsystem, the corresponding retry/recovery procedure is the responsibility of the SRP protocol. These procedures are described in Clause 35 of IEEE Std 802.1Q-2011.

11.4.4.4 TS setup procedures for both AP and non-AP STA initiation

The non-AP STA's SME decides that a TS needs to be created. How it does this, and how it selects the TSPEC or DMG TSPEC parameters, is beyond the scope of this standard. The SME generates an MLME-ADDS.request primitive containing a TSPEC or DMG TSPEC. A TSPEC or DMG TSPEC may also be generated autonomously by the MAC without any initiation by the SME.

NOTE—Such a TPSEC or DMG TPSEC might be overridden as a result of a subsequent MLME-ADDS.request primitive from the SME (see 11.4.4.5)

The STA's MLME transmits the TSPEC or DMG TSPEC in an ADDTS Request frame to the HC/non-AP STA. If the non-AP STA's MLME is in power save mode, the STA shall include its DMG Wakeup Schedule element in the ADDTS Request frame variant and in the DMG ADDTS Request frame variant.

The HC/non-AP STA's MLME receives this Management frame and generates an MLME-ADDS.indication primitive to its SME containing the TSPEC or DMG TSPEC.

The SME in the HC/non-AP STA decides whether to admit the TSPEC or DMG TSPEC with its associated TCLAS element(s) (if present) and TCLAS Processing element (if present), as specified, refuse the TSPEC or DMG TSPEC, or not admit but suggest an alternative TSPEC, DMG TSPEC, or TCLAS element(s), or TCLAS Processing element.

A DMG STA that responds with an ADDTS Response frame and an HC may change the value of parameters that have been set unspecified by the STA to any value that it deems appropriate, including leaving them unspecified.

If the TSPEC or DMG TSPEC is received from a non-AP STA by an AP when dot11SSPNInterfaceActivated is true, the HC shall use the permissions stored in dot11InterworkingEntry for that STA in the decision to admit or deny the request (see 11.25.5.3). The SME then generates an MLME-ADDS.response primitive containing the TSPEC or DMG TSPEC, zero or more TCLAS element(s) (only if present in the request) and TCLAS Processing element (only if present in the request) and a ResultCode value. The contents of the TSPEC or DMG TSPEC field, TCLAS element(s) (if present), TCLAS

Processing element (if present), and ResultCode field contain values specified in 6.3.26.5.2. The SME may include fewer TCLAS elements in the MLME-ADDTS.response primitive than were present in the request; when the SME’s response includes a single TCLAS element, it shall not include a TCLAS Processing element. If the SME changes a TCLAS element’s Classifier Type field in the MLME-ADDTS.response primitive but is unable to suggest a value for the Classifier Mask field, it shall set that field to 0. If the SME changes a TCLAS element’s Classifier Type field or Classifier Mask field in the MLME-ADDTS.response primitive but is unable to suggest values for one or more Classifier Parameter subfields, it shall set those subfields to 0.

When the HC in an AP that has dot11SSPNInterfaceActivated equal to true receives a TSPEC, the AP shall inspect it to determine the requested access policy, user priority, and mean data rate as follows:

- a) The access category shall be determined from the user priority according to Table 10-1. For a TS to be admitted when the requested access policy is EDCA, both of the following shall be true:
 - 1) The field corresponding to this access category in dot11NonAPStationAuthAccessCategories from the non-AP STA’s dot11InterworkingEntry is equal to 1.
 - 2) The sum of the mean data rate of all of the requesting STA’s active TSs in this access category plus the mean data rate in the TSPEC is less than or equal to the non-AP STA’s dot11InterworkingEntry for dot11NonAPStationAuthMaxVoiceRate, dot11NonAPStationAuthMaxVideoRate, dot11NonAPStationAuthMaxBestEffortRate, or dot11NonAPStationAuthMaxBackgroundRate depending on whether the derived access category is AC_VO, AC_VI, AC_BE or AC_BK, respectively.
- b) For a TS to be admitted when the requested access policy is HCCA, all of the following shall be true:
 - 1) The dot11NonAPStationAuthHCCAHEMM value is true.
 - 2) The sum of the mean data rate of all of the requesting STA’s active TSs having access policy set to HCCA plus the mean data rate in the TSPEC is less than or equal to dot11NonAPStationAuthMaxHCCAHEMMRate in the non-AP STA’s dot11InterworkingEntry.
 - 3) The delay bound that will be provided by the HC in the TSPEC response is less than or equal to dot11NonAPStationAuthHCCAHEMMDelay in the non-AP STA’s dot11InterworkingEntry.

If the DMG TSPEC is admitted, the AP or PCP shall set the ResultCode to SUCCESS_STA_IN_PS_MODE if the STA identified by destination AID is in power save mode and shall include in the ADDTS Response frame the DMG Wakeup Schedule element of the destination DMG STA if one is established. In this case, the AP or PCP should defer including the TS schedule in the Extended Schedule element until both source DMG STA and destination DMG STA are in active mode.

The HC/non-AP STA’s MLME transmits an ADDTS Response frame containing this TSPEC or DMG TSPEC and status. The encoding of the ResultCode values to Status Code field values is defined in Table 9-46. The AP or PCP shall transmit the ADDTS Response frame to the STAs identified as source and destination AID of the DMG TSPEC contained in the ADDTS Request frame if the ADDTS request is sent by a non-AP and non-PCP STA. If the ResultCode is SUCCESS, the AP or PCP shall announce the creation of the allocation by setting the Allocation ID subfield in the TSPEC element sent in the ADDTS Response frame to a nonzero value and also by delivering the Extended Schedule element as defined in 10.36.6. In an AP when dot11SSPNInterfaceActivated is true, the HC shall set the dot11NonAPStationAddtsResultCode in the non-AP STA’s dot11InterworkingEntry equal to the ResultCode.

The STA’s MLME receives this Management frame. It generates an MLME-ADDTS.confirm primitive to its SME containing the TSPEC or DMG TSPEC and status.

The SME decides whether the response meets its needs. How it does this is beyond the scope of this standard. A SME receiving a modified TCLAS element having a Classifier Mask field equal to 0 or

Classifier Parameter subfields equal to 0 should regard these values as meaning that no suggested value has been provided by the HC.

- If the result code is SUCCESS, the TS enters into an active state.
- If the result code is REJECTED_WITH_SUGGESTED_BSS_TRANSITION, the non-AP STA may try to transition to other BSSs. In case that the non-AP STA is recommended to transition to other BSSs, it should do so according to the process defined in 11.24.7. Once the transition is completed, it should proceed with a TS setup process with the new HC.
- Otherwise, the whole process can be repeated using the same TSID and direction, a modified TSPEC or DMG TSPEC, optional TCLAS element(s), and an optional TCLAS Processing element until the SME decides that the granted medium time is adequate or inadequate and cannot be improved.

The above rules also apply to the negotiation of the PTP TSPEC and to the negotiation of the DMG TSPEC.

The parameters that are set for a TS may be renegotiated in a similar manner (see 11.4.4.5).

If the HC/PCP grants medium time for an ADDTS Request frame with the Ack Policy subfield equal to Block Ack and the Direction field equal to either downlink or bidirectional, then it shall initiate a block ack negotiation by sending an ADDBA Request frame to the STA that originated the ADDTS Request frame. If a non-DMG STA is granted medium time for an ADDTS Request frame with the Ack Policy subfield equal to Block Ack and the Direction field equal to other than downlink, then it shall initiate a block ack negotiation by sending an ADDBA Request frame to the recipient of the TS.

In a non-DMG BSS, the combination of the TSID and Direction subfields identify the TS, in the context of the STA, to which the TSPEC applies. A bidirectional link request is equivalent to a downlink TS and an uplink TS, each with the same TSID and parameters. In a DMG BSS, the combination of the TSID, source DMG STA AID, destination DMG STA AID, and Direction subfields identifies the TS, in the context of the non-AP STA, to which the TSPEC applies.

The same TSID may be used for multiple TSs at different STAs. A STA can use the same TSID subfield value for a downlink TSPEC and either an uplink or a direct-link TSPEC at the same time. In a non-DMG BSS, a non-AP STA shall not use the same TSID for both uplink and direct-link TS. In a DMG BSS, a non-AP STA as a source DMG STA can use the TSID subfield value for an uplink PTP TSPEC, and at the same time the non-AP STA as a destination DMG STA can use the same TSID subfield value for a downlink PTP TSPEC.

If the TS Info Ack Policy subfield of a TSPEC or DMG TSPEC element is Block Ack and the type of Block Ack policy is unknown to the HC, the HC assumes, for TXOP scheduling, that the immediate block ack policy is being used (see 10.24).

An HC shall be capable of receiving an ADDTS Request frame that contains a TCLAS element and capable of generating an indication that contains this as a parameter.

When a STA requests service at a higher priority than authorized by its dot11InterworkingTableEntry, the HC may provide a suggested TSPEC or DMG TSPEC with a data rate and lower priority that would be authorized. Usage of the TSPEC in an Interworking environment is described in Annex K.

A STA may include a U-PID element in ADDTS Request, DMG ADDTS Request, ADDTS Response and DMG ADDTS Response frames it transmits. The U-PID element is used to indicate the upper layer protocol responsible for handling MSDUs corresponding to the TID indicated within the frame carrying the U-PID element. If a U-PID element is not included in an ADDTS Request, DMG ADDTS Request, ADDTS Response or DMG ADDTS Response frame, MSDUs corresponding to the TID contain an LLC header that is used for upper layer protocol identification.

A U-PID element shall not be included in an ADDTS Response or DMG ADDTS Response frame if a U-PID element was not included in the corresponding ADDTS Request or DMG ADDTS Request frame. If a U-PID element was included in an ADDTS Request or DMG ADDTS Request frame, the same U-PID element shall be included in the corresponding ADDTS Response or DMG ADDTS Response frame if that frame has a Status Code of SUCCESS. The Status Code field shall be set to REJECT_U-PID_SETTING in the ADDTS Response or DMG ADDTS Response frame if the request is rejected frame due to the setting of the U-PID element received; this frame may contain an alternative U-PID element that is acceptable to the STA sending the ADDTS Response or DMG ADDTS Response frame.

11.4.4.5 TS renegotiation

A non-AP STA may attempt to modify the parameters of a TSPEC or DMG TSPEC by transmitting an ADDTS Request or DMG ADDTS Request frame. If the Status Code in the corresponding ADDTS Response or DMG ADDTS Response frame is SUCCESS, then any TSPEC with the same TSID or DMG TSPEC with the same allocation ID is overridden with the TSPEC or DMG TSPEC in that frame, the HC and non-AP STA shall reset the inactivity interval timer, and the HC shall reset the suspension interval timer.

11.4.5 TS setup by resource request during a fast BSS transition

A QoS STA may transmit a TSPEC as part of a RIC-Request in a resource request message. The SME in the hybrid coordinator (HC) decides whether to accept the TSPEC as specified, or refuse the TSPEC, or not accept but suggest an alternative TSPEC. It then generates a RIC-Response, according to the procedures given in 13.11.

Each TS established by this resource request is placed in the accepted state. This state is an intermediate state between inactive and active. In the accepted state, the inactivity and suspension timers shall not be started for the TS. For a TS based on hybrid coordination function (HCF) controlled channel access (HCCA), the HC shall not generate CF-Poll for the TS.

The SME may take the resource/timing requirements of the TS in the accepted state into consideration before assigning any further resources to any other admitted or accepted TS, and in calculating the available admission capacity for the BSS Load element.

The TS is moved to the active state once the STA performs a reassociation to the AP (see 13.11.3). Once the TS becomes active, the inactivity and suspension timers are started. In an AP when dot11SSPNInterfaceActivated is true, the HC shall set the dot11NonAPStationAddtsResultCode in the non-AP STA's dot11InterworkingEntry equal to the Status Code in the corresponding RDE.

If the reassociation timer times out and the TS is not yet in the active state, the TS goes back to the inactive state.

11.4.6 PSMP management

A STA may attempt to create a scheduled PSMP session with its AP only if the AP has the S-PSMP Support field in the Extended Capabilities element equal to 1.

The TSPEC reserves resources within the AP and modifies the AP's scheduling behavior. The parameters in the TSPEC can be grouped into two categories: PSMP scheduling and PSMP reservation. The scheduling parameters are used by the AP to schedule a suitable SI. The reservation parameters are used by the AP to reserve time in the PSMP-UTT and PSMP-DTT.

The service start time and SI specify the PSMP schedule in the response's Schedule element. All other parameters result in a reservation for the PSMP-UTT and PSMP-DTT within the scheduled PSMP sequence.

An AP shall terminate the PSMP session only when the last TS associated with the particular PSMP session is terminated.

Once created, a PSMP session can be extended by another TSPEC setup. A STA that has an established PSMP session may issue an additional TSPEC request with the following:

- The Aggregation field set to 1
- The Scheduled field set to 1 and APSD field set to 0 (S-PSMP)
- The Minimum Service Interval and Maximum Service Interval fields both set to the Service Interval field value from the Schedule element specified when the PSMP session was established

The AP shall return an identical Schedule element for all TSPEC response frames related to the same PSMP session.

NOTE—A STA that does not have an established PSMP session might send a TSPEC request specifying S-PSMP session with the same SI. The AP is free to choose between aggregating this request with an existing PSMP session of the same SI or creating a new PSMP session.

The parameters of a TS already associated with the PSMP session may be changed; however, the SI shall not be changed. The start time of existing STAs in the PSMP schedule shall not be changed by the addition of a TSPEC from a new STA.

A TSPEC that reserves resources for a STA under scheduled PSMP shall have the APSD and Scheduled fields set to indicate Scheduled PSMP as defined in Table 9-142.

The non-AP STA's SME decides that a PSMP session needs to be established. How it makes this decision and how it selects the related TSPEC parameters are beyond the scope of this standard.

The Minimum Service Interval field of the TSPEC element of an ADDTS Request frame shall be a multiple of the SI granularity indicated by the AP in its Extended Capabilities element.

11.4.7 Failed TS setup

There are three possible types of failed TS setup:

- a) The transmission of ADDTS Request frame failed.
- b) No ADDTS Response frame is received from the HC/non-AP STA (e.g., because of delay due to congestion or because the response frame cannot be transmitted).
- c) An ADDTS Response frame is received that contains the Status Code field equal to REJECTED_FOR_DELAY_PERIOD. In this case, if the Delay field of the TS Delay element of the ADDTS Response frame is nonzero, the STA that transmitted the ADDTS Request frame shall not transmit another ADDTS Request frame to the same AP until the time indicated by the Delay field has elapsed.

Figure 11-17 summarizes the two cases. In either case in a non-DMG BSS, if the request is not for an existing TS, the SME shall issue a DELTS.request to the HC specifying the TSID and direction of the failed request just in case the HC had received the request and it was the response that was lost. In either case in a DMG BSS, if the request is not for an existing allocation or TS, the SME shall issue a DELTS.request to the non-AP STA specifying the allocation ID or TSID and destination DMG STA of the failed request just in case the AP or PCP had received the request and it was the response that was lost.

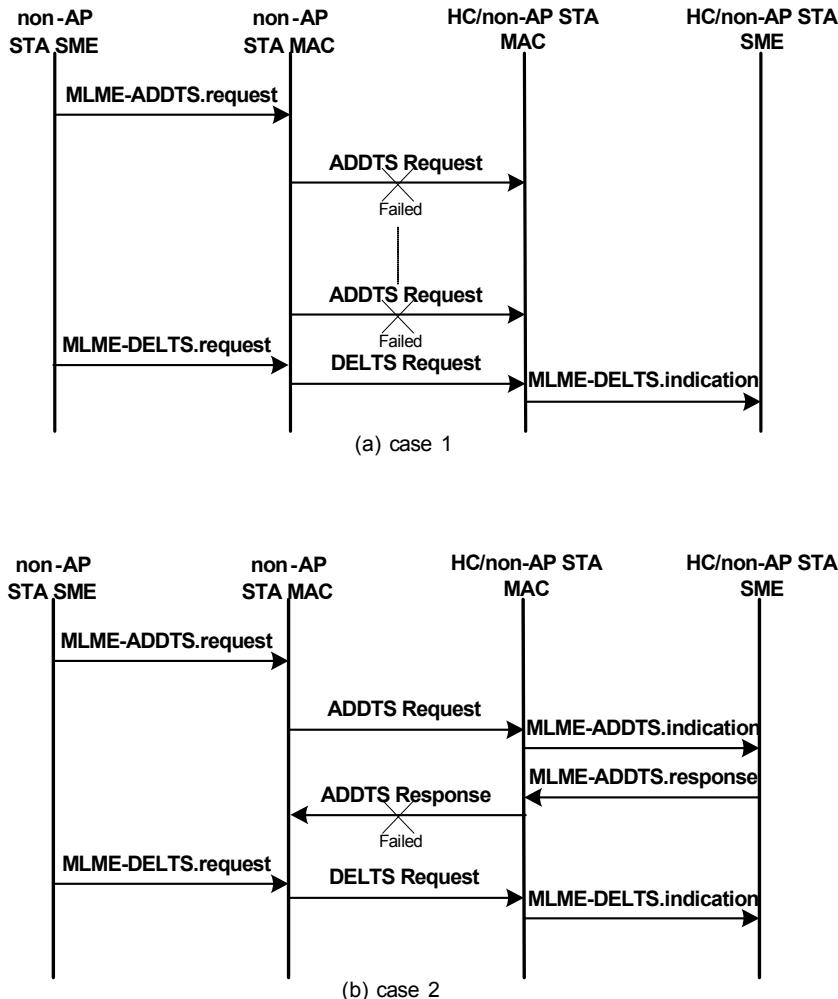

Figure 11-17—Failed TS setup detected within non-AP STA’s MLME

11.4.8 Data transfer

After the setup of a TSPEC or PTP TSPEC, MSDUs are classified above the MAC and are sent to the MAC through the MAC SAP using the MA-UNITDATA.request primitive with the priority parameter encoded to the TID.

In a DMG BSS, MSDUs are transmitted using QoS Data frames. During each CBAP allocation, the MAC delivers MSDUs based on the priority of the transmitted QoS Data frames. The MAC can transmit all MSDUs having a TSID with an associated TSPEC with an access policy of EDCA or SEMM, provided that the source AID of the CBAP allocation is equal to the source AID of the TS, or the source AID of the CBAP allocation is equal to broadcast AID, or the destination AID of the CBAP matches the destination AID of the TS.

During each SP allocation, the MAC delivers MSDUs whose TSIDs identify TSPECs that have been set up to use the SP allocation. Relative prioritization of multiple TSPECs mapped to the same SP allocation is implementation dependent and outside the scope of this standard.

When an MSDU arrives from the MAC SAP with a TSID for which there is no associated TSPEC, the MSDUs shall be sent using EDCA with the access category AC_BE.

The generation of the associated TID is done by a classifier above the MAC, and it may use the associated TCLAS elements if any are present. When there are multiple TCLAS elements and if the Processing subfield of TCLAS Processing element is 0, the priority parameter in the associated MA-UNITDATA.request primitive is set to TID if the classifier matches the parameters in all of the TCLAS elements associated with the TS. When there are multiple TCLAS elements and if the Processing subfield of the TCLAS Processing element is 1, the priority parameter in the associated MA-UNITDATA.request primitive is set to TID if the classifier matches the parameters in at least one of the TCLAS elements associated with the TS. When there is no TCLAS element and if the Processing subfield of the TCLAS Processing element is 2, the priority parameter in the associated MA-UNITDATA.request primitive is set to TID if the classifier cannot match the parameters to any of the TCLAS elements. An incoming MSDU that is not classified to a particular TS may be classified to another active TS based on the frame classifier for that TS. If, however, all of the frame classifiers for the active TS have been exhausted, the MSDU does not belong to any active TS and is classified to be a best-effort MSDU. See 5.1.1.3 for the treatment of an MSDU with a TSID for which there is no associated TSPEC.

When an MSDU is classified using a TCLAS element, the original UP cannot be recovered by the receiver.

If dot11AlternateEDCAActivated is true, if an Intra-Access Category Priority element was provided when the TS was created, and if the Access Policy subfield of the TS Info field in the TSPEC is EDCA or HEMM, the value from the Alternate Queue subfield is used to select the appropriate EDCA transmit queue.

If an Intra-Access Priority element was provided when the TS was created, the Drop Eligibility subfield is used to determine the drop eligibility of the MSDU.

11.4.9 TS deletion

11.4.9.1 Deletion of a TS established between an HC, DMG AP, or PCP and a non-AP and non-PCP STA

The STA may delete a TS in either of two ways: using non-PCP / non-AP STA initiation or using HC, DMG AP or PCP initiation. In both methods, the SME entity above the MAC generates an MLME-DELTS.request primitive specifying the TS to be deleted and the reason for deleting the TS. This causes the MAC to send a DELTS frame. The encoding of ReasonCode values to Reason Code field values is defined in Table 9-45.

Having transmitted a DELTS frame, the initiating MAC deletes the TS identified in the DELTS frame when it receives an Ack frame that responds to this DELTS frame. There is no Management frame response.

Figure 11-18 shows the case of TS deletion initiated by a non-PCP and non-AP STA and the case of TS deletion initiated by an HC, DMG AP, or PCP.

An HC should not delete a TSPEC without a request from the SME, except for inactivity (see 11.4.10) or an HC service change that precludes the HC from continuing to meet the requirements of the TSPEC.

All TSPECs that have been set up shall be deleted upon disassociation and reassociation. Reassociation causes the non-PCP and non-AP STA and HC, DMG AP, or PCP to clear their states, and the non-PCP and non-AP STA may then reinitiate the setup.

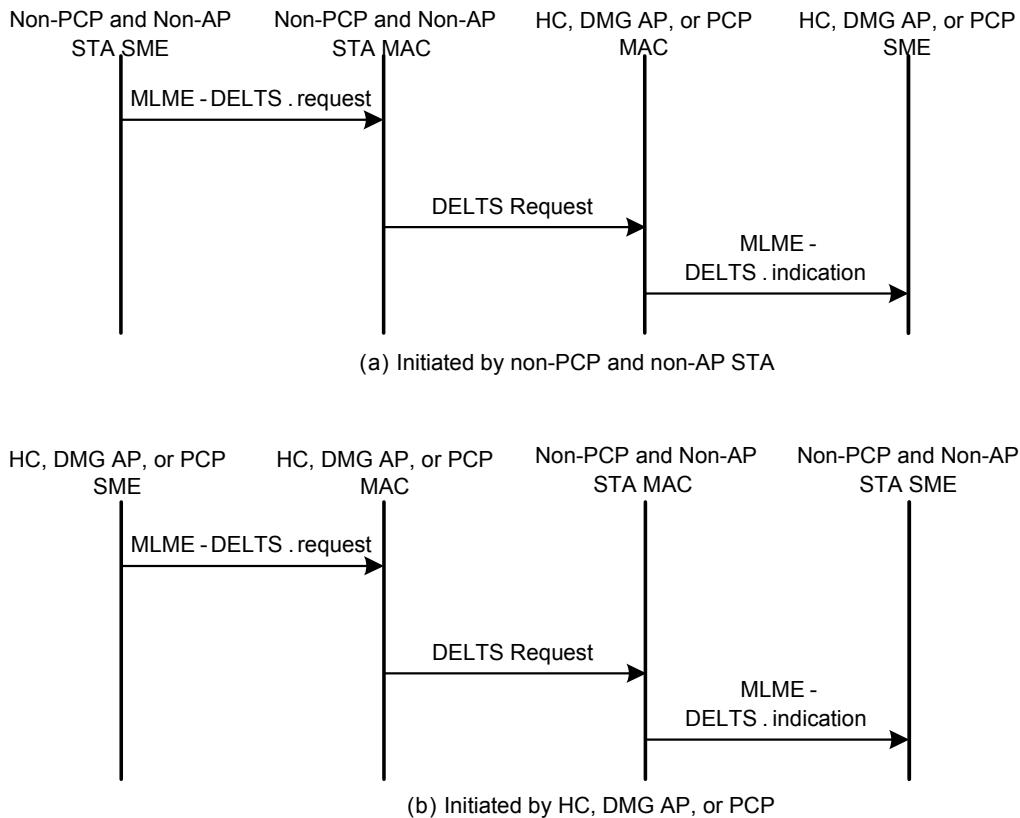

Figure 11-18—TS deletion

11.4.9.2 Peer-to-peer TS deletion and deletion of an allocation

This subclause describes deletion of a TS established between non-AP and non-PCP DMG STAs (i.e., established using a PTP TSPEC) and deletion of an allocation (i.e., established using a DMG TSPEC).

In this subclause the following procedures for deletion of an allocation or TS are described:

- Deletion of a TS established using a PTP TSPEC by either source or destination STAs
- Deletion of an allocation by either source or destination STAs of that allocation, which might result in the deletion of one or more associated TSs
- Deletion of an allocation (either SP or CBAP) by the AP or PCP

The SME entity above the MAC generates an MLME-DELTS.request primitive specifying either the TS or the allocation to be deleted and the reason for deleting the TS or allocation, respectively. If generated within a non-AP and non-PCP STA, this primitive causes the MAC to send a single DELTS frame. If generated within an AP or PCP, this primitive causes the MAC to send one or two DELTS frames, as described below. The encoding of ReasonCode values to Reason Code field (see 9.4.1.7) values is defined in Table 9-45.

A STA that receives an MLME-DELTS.request primitive for a TS that was established using a PTP TSPEC causes the MAC to send a DELTS frame to the peer STA of the TS. This is shown in Figure 11-19.

NOTE—The AP or PCP is unaware of the deletion of the TS.

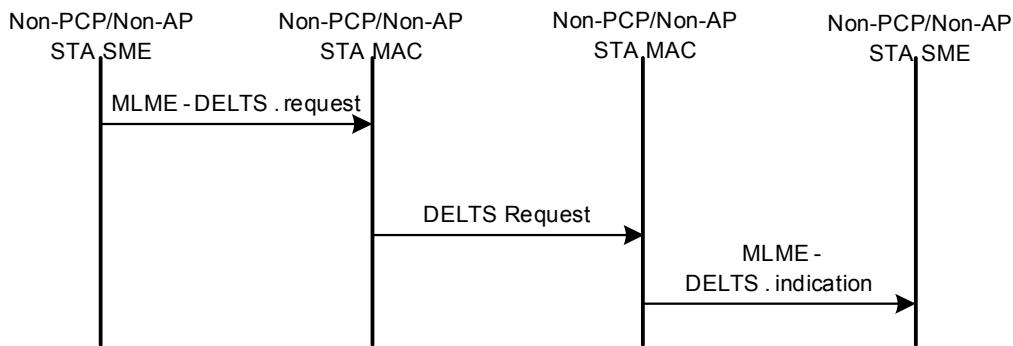

Figure 11-19—Deletion of a TS established using a PTP TSPEC

A non-AP and non-PCP STA that receives an MLME-DELTS.request primitive for an allocation causes the MAC to send a DELTS frame to the AP or PCP. If it is transmitted by the STA identified by the Source AID of the allocation and if the Destination AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Destination AID of the allocation. If it is transmitted by the STA identified by the Destination AID of the allocation and if the Source AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Source AID of the allocation. The AP or PCP shall also delete the scheduling information corresponding to the allocation, identified by the DMG Allocation Info field of the DELTS frame.

Figure 11-20 shows the deletion of an allocation in which both Source AID and Destination AID are not the broadcast AID.

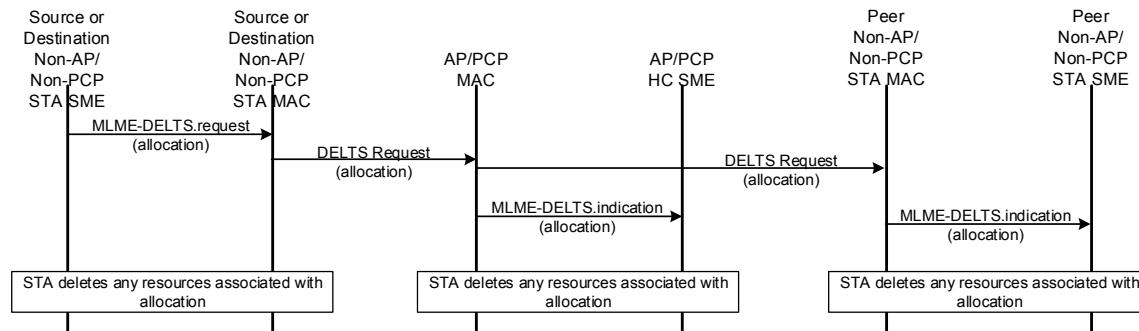

Figure 11-20—Deletion of an allocation in which both Source AID and Destination AID are not the broadcast AID

An AP or PCP that receives an MLME-DELTS.request primitive for an allocation causes the MAC to send one or two DELTS frames. If the Destination AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Destination AID of the allocation. If the Source AID of the allocation is different from the broadcast AID, the AP or PCP shall send a DELTS frame to the STA identified by the Source AID of the allocation. The AP or PCP shall also delete the scheduling information corresponding to the allocation, identified by the DMG Allocation Info field of the DELTS frame.

An SME that deletes an allocation (using a MLME-DELTS.request primitive) or is notified that an allocation has been deleted (by receiving an MLME-DELTS.indication primitive) also locally deletes (i.e., updates its own resources, but does not cause any MAC frames to be transmitted) any TS that is dependent on that allocation as follows:

- Deleting an SP allocation shall also locally delete any TS with access policy SPCA or SEMM using the allocation.
- Deleting a CBAP allocation with Source AID different from the broadcast AID shall also locally delete any TS with access policy EDCA using the allocation.
- Deleting a CBAP allocation with Source AID equal to the broadcast AID shall also locally delete any TS with access policy EDCA using the allocation, unless there is another CBAP allocation the TS could use.

A non-AP and non-PCP STA that associates, disassociates or reassociates (except for reassociation to the same AP) shall locally delete all existing allocations and all TSs that have been established using a PTP TSPEC.

An AP or PCP that receives an MLME-ASSOCIATE.indication, MLME-REASSOCIATE.indication (except when the MLME-REASSOCIATE.indication primitive has this AP's MAC address in the CurrentAPAddress parameter) or MLME-DISASSOCIATE.indication primitive from a STA (the “resetting” STA) with which it has an existing association shall locally delete all allocations that have been established by the resetting STA using a PTP TSPEC. When deleting an allocation in which the Source AID or Destination AID correspond to the resetting STA and the peer STA is not identified by the broadcast AID, the AP or PCP shall send a DELTS to the peer STA to delete that allocation.

NOTE—If both Source AID and Destination AID are equal to the broadcast AID, the AP or PCP transmits no DELTS frames. It deletes scheduling information corresponding to the allocation, which is reflected in its subsequent transmission of frames containing an Extended Schedule element.

A STA that generates an MLME-ASSOCIATE.request, MLME-REASSOCIATE.request (except when the MLME-REASSOCIATE.request primitive has the target AP's MAC address in the CurrentAPAddress parameter) or MLME-DISASSOCIATE.request primitive shall locally delete all allocations and all TSs that have been established using a PTP TSPEC.

NOTE—Reassociation causes a STA to clear any state related to allocations and TSs that have been established using a PTP TSPEC. A non-PCP and non-AP STA might need to repeat the establishment of any allocations or TSs after reassociation needed to support applications active before the reassociation.

In all of the cases listed above, the TS or allocation is deleted within the initiating MAC when the Ack frame to the Action frame is received. No Action frame response is generated.

11.4.10 TS timeout

TS timeout is detected within the HC/non-AP STA's MAC when no traffic is detected on the TS within the inactivity timeout specified when the TS was created.

For an uplink TS in a non-DMG BSS or for a TS that has the AP or PCP as the destination DMG STA in a DMG BSS, the timeout is based on the arrival of received MSDUs that belong to the TS, after any decryption and reassembly.

For a downlink TS in a non-DMG BSS or for a TS that has the AP or PCP as the source DMG STA in a DMG BSS, the timeout is based on the following:

- Arrival of valid MA-UNITDATA.request primitives using this TS at the MAC SAP when the QoS Data frames are sent with the Ack Policy subfield equal to No Ack
- Confirmation of correctly sent MSDUs that belong to the TS within the MAC when the QoS Data frames are sent with the Ack Policy subfield set other than to No Ack

In a DMG BSS and in the case of a TS that is established between non-AP STAs (PTP TSPEC), the timeout of the recipient is based on the arrival of MSDUs that belong to the TS within the MAC after any decryption, A-MSDU unpacking, and reassembly.

In a TS established between non-AP STAs (PTP TSPEC), the timeout of the originator is based on the following:

- Arrival of valid MA-UNITDATA.request primitives using this TS at the MAC SAP when the QoS Data frames are sent with the Ack Policy subfield set to No Ack
- Confirmation of correctly sent MSDUs that belong to the TS within the MAC when the QoS Data frames are sent with the Ack Policy subfield set other than to No Ack

In a direct-link TS in a non-DMG BSS, inactivity is considered to have happened if one of the two following events occurs:

- The HC transmits a QoS CF-Poll frame and the polled STA returns a QoS Null immediately after a SIFS that contains a QoS Control field in which the Queue Size subfield contains 0.
- The HC transmits a QoS CF-Poll frame, and no QoS Null frame is received within the granted TXOP duration that indicates the queue size for the related TSID. This is to confirm that the STA is actually using the assigned TXOP for the given TSID.

In a non-DMG BSS, any other use of a polled TXOP delivered to the STA is considered to be activity on all direct-link TS associated with that STA. Detection of inactivity of this type is optional.

In response to an inactivity timeout, an HC shall send a DELTS frame to the STA with the Reason Code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive. In response to an inactivity timeout, a DMG AP shall send a DELTS frame to the non-AP DMG STA with the result code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive. In response to an inactivity timeout, a PCP shall send a DELTS frame to the non-PCP DMG STA with the result code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive.

In a DMG BSS when a TS is established between non-AP STAs (PTP TSPEC), then in response to a TS timeout detected within the originator non-AP STA the non-AP STA shall send a DELTS frame to the recipient non-AP STA with the result code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive. If the TS timeout is detected within the recipient non-AP STA, the STA shall send a DELTS frame to the originator non-AP STA with the result code set to TIMEOUT and inform its SME using the MLME-DELTS.indication primitive.

The case of uplink TS timeout is shown in Figure 11-21.

11.4.11 TS suspension

TS suspension occurs within the HC's MAC when no traffic is detected on the TS within the suspension interval specified when the TS was created. In the suspended state, the generation of QoS (+)CF-Poll frames is stopped for the related TS.

11.4.12 TS reinstatement

A suspended TS may be reinstated following activity for that TS.

For uplink and direct link, a suspended TS may be reinstated by a STA by sending a QoS Data or QoS Null frame. This frame may be sent at the highest priority using EDCA. The generation of successive QoS (+)CF-Poll frames shall then be resumed by the HC.

For downlink, a suspended TS is reinstated by the HC when the AP receives an MSDU from a higher layer.

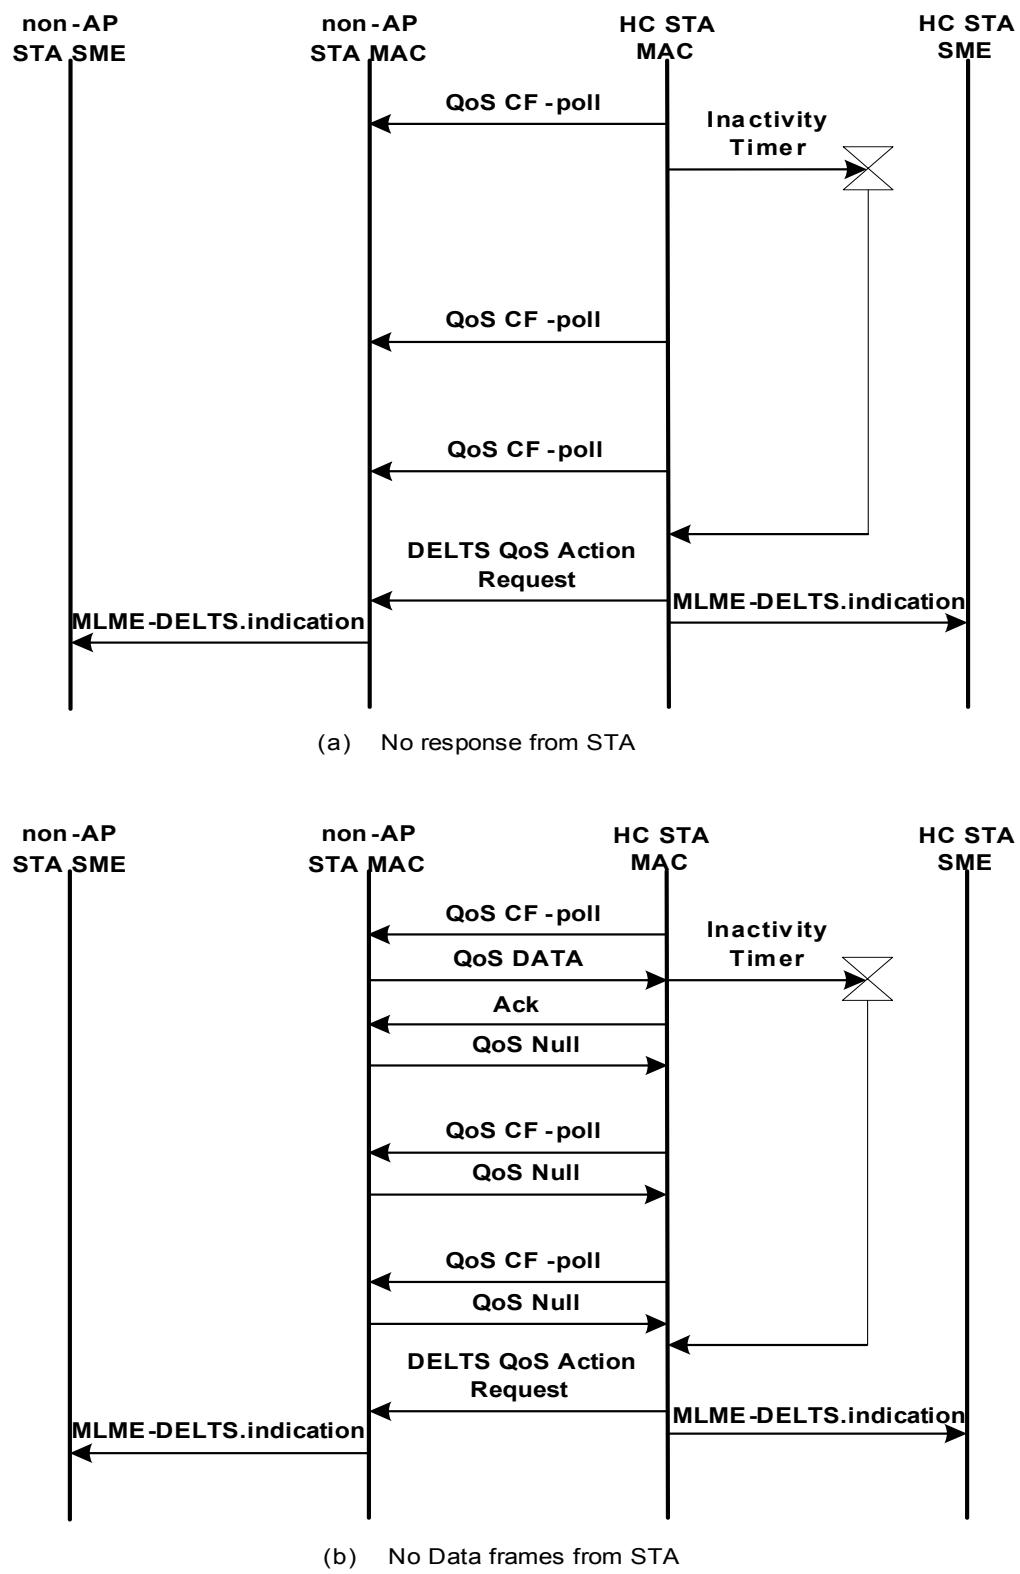

Figure 11-21—TS timeout

11.4.13 DMG allocation formats

11.4.13.1 General

A DMG STA manages allocations and TSs as described in 11.4.1 to 11.4.14. Using the DMG TSPEC, a DMG STA can indicate two types of allocation scheduling: isochronous and asynchronous. It should establish an isochronous allocation if it needs periodic access to the channel and does not expect to change the amount of time allocated frequently. It should establish an asynchronous allocation if it expects to make requests for channel time and wishes to reserve a minimum amount of channel time to satisfy those requests when they occur.

11.4.13.2 Isochronous allocations

In order to request the setup of an isochronous allocation, a DMG STA shall set the Allocation Format field in the DMG TSPEC element to 1.

Following the successful admittance of a DMG TSPEC with an isochronous allocation, the AP or PCP should allocate time in the beacon interval to meet the periodicity and minimum allocation requirements specified in the DMG TSPEC element.

Referring to fields in the DMG TSPEC element, the AP or PCP should check that over each Allocation Period the sum of the time allocations is at least the Minimum Allocation. In addition, the AP or PCP should check that each individual allocation has a minimum duration of at least Minimum SP Duration. See 9.4.2.134, 10.36.6, and 10.36.6.4.

With an isochronous DMG TSPEC, the allocation period defines the period over which the channel time allocation repeats. The scheduler should check that at least the minimum allocation is made within each allocation period. The allocation may be composed of multiple SPs. The scheduler also checks that each SP making up the allocation is no shorter than the minimum SP duration. The scheduler is free to position the SPs that make up the allocation anywhere in the allocation period. The scheduler may allocate up to the maximum allocation each allocation period if resources permit.

11.4.13.3 Asynchronous allocations

A DMG STA uses the SPR frame to request channel time for asynchronous traffic.

For each TID, source DMG STA, and destination DMG STA tuple, the AP or PCP can maintain the amount of outstanding channel time that needs to be allocated. Each time it receives an SPR frame, the amount of outstanding channel time is set to the value received in the SPR frame from the source DMG STA for the identified TID and destination DMG STA. The amount of outstanding channel time is decreased by the amount allocated when channel time is scheduled for that TID, source DMG STA, and destination DMG STA tuple.

A DMG STA may also use a DMG TSPEC to reserve resources for asynchronous traffic. In this case, the STA shall set the Allocation Format field in the DMG TSPEC element to 0. The AP or PCP should admit an asynchronous DMG TSPEC only if it is able to meet the minimum allocation requirements specified in the DMG TSPEC element.

With an asynchronous DMG TSPEC, a DMG STA registers the minimum allocation it expects within the allocation period while an SP request is in effect that is greater than the minimum allocation specified. In addition, the STA expects that each allocation is at least of duration specified by the Minimum Duration field of the DMG TSPEC, provided the outstanding SP request is at least that long. In admitting a DMG TSPEC, the AP or PCP should check that there are sufficient resources available to meet the TSPEC requirements.

11.4.14 PTP TS operation

The ADDTS Request frame containing the PTP TSPEC may be sent to the peer non-AP DMG STA directly or through a DMG AP or PCP.

A non-AP DMG STA may add TSs to an existing allocation with a peer non-AP DMG STA. To do this, the non-AP DMG STA transmits an ADDTS Request frame to the peer STA to include the additional TS. The ADDTS Request frame shall contain a PTP TSPEC with the Allocation ID subfield set to indicate the allocation for the additional TS. A TS with EDCA access policy does not need to be added to any CBAP allocation and can use any CBAP allocation as long as the source AID of the CBAP allocation matches the source AID of the TS, or the source AID of the CBAP allocation is equal to the broadcast AID, or the destination AID of the CBAP matches the destination AID of the TS.

A non-AP DMG STA transmits an ADDTS Request frame to a peer non-AP DMG STA to add a TS to an existing allocation and to possibly communicate traffic-specific parameters such as A-MSDU subframe and Maximum MSDU Size with the peer non-AP DMG STA. The non-AP DMG STA may transmit the ADDTS Request frame directly to the peer STA or to the AP or PCP. In the latter case, the ADDTS Request frame shall contain a TCLAS element with the classifier type set to Ethernet parameters; the Source Address field shall contain the address of the STA that sends the ADDTS Request frame; and the Destination Address field shall contain the address of the peer STA, which is used by the AP or PCP to forward to the peer STA.

The AP STA or PCP STA shall forward the received ADDTS Request frame to the STA with Address equal to the Destination Address field of the Classifier. If an ADDTS Response frame is received by the AP STA or PCP STA in response to the forwarded ADDTS Request frame, then the AP STA or PCP STA shall forward the ADDTS Response frame to the STA with Address equal to the Source Address field of the Classifier. The AP DMG STA and the PCP DMG STA shall not change the content of the elements included in the ADDTS Request and ADDTS Response frames.

If a STA sets the Direction field to a value equal to downlink in the PTP TSPEC included in the ADDTS Request frame, the parameters apply to the STA as the destination DMG STA of that TS. For example, in this case, the Maximum MSDU Size field indicates that the STA is not able to receive MSDUs longer than the value presented in the MSDU Size field. Similarly, if the Direction field indicates uplink, the parameters apply to the STA as the source DMG STA of that TS. In this case, the STA that issued the ADDTS Request frame does not send MSDUs longer than the value of the Maximum MSDU Size field.

11.5 Block ack operation

11.5.1 Introduction

Block ack may be set up at the MAC (see 10.24.2) or by the initiation of SME. The setup and deletion of block ack at the initiation of the SME is described in this subclause.

11.5.2 Setup and modification of the block ack parameters

11.5.2.1 General

The procedures for setting up and modifying the block ack parameters are described in 11.5.2.2 and 11.5.2.3, respectively, and illustrated in Figure 11-22.

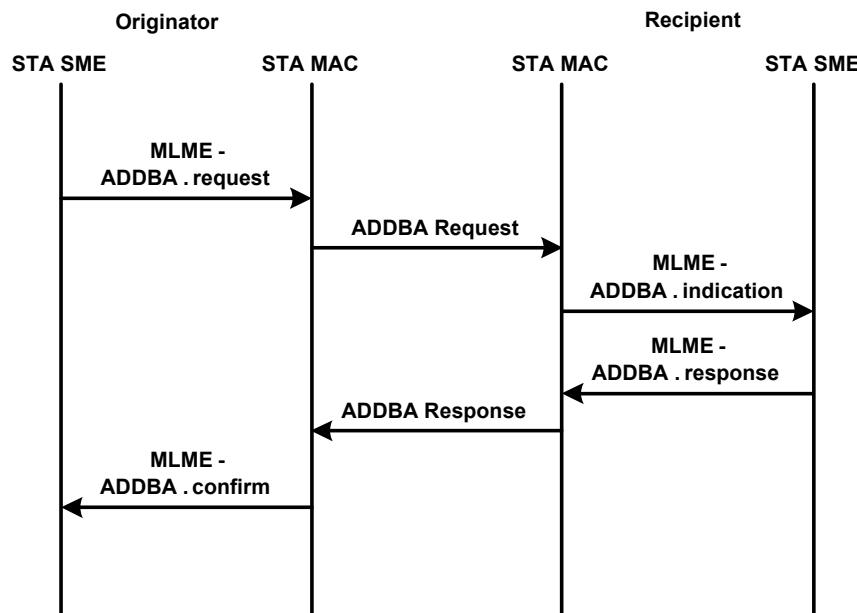

Figure 11-22—Block ack setup

11.5.2.2 Procedure at the originator

Upon receipt of an MLME-ADDBA.request primitive, an initiating STA that intends to send QoS Data frames under the block ack mechanism shall set up the Block Ack using the following procedure:

- a) If the initiating STA is an HT STA, is a member of an IBSS, and has no other existing block ack agreement with the recipient STA, then the initiating STA shall transmit a Probe Request frame to the recipient STA and shall not transmit an ADDBA Request frame unless it receives a Probe Response frame from the recipient.

NOTE—When the block ack agreement is being established between a non-AP STA and its AP, then the originator and the recipient have exchanged capability information during the association exchange that allows them to determine whether the other STA is an HT STA. If the STA is establishing a block ack agreement with another STA through DLS, then the DLS setup procedure includes the exchange of capability information that allows both STAs to determine whether the other STA is an HT STA.

- b) If the peer STA is a non-DMG STA, check whether the intended peer STA is capable of participating in the block ack mechanism by discovering and examining its Delayed Block Ack and Immediate Block Ack capability bits. If the recipient is capable of participating, the originator sends an ADDBA Request frame indicating the TID and the buffer size. If the recipient is capable of participating and the GCRGroupAddress parameter of the MLME-ADDBA.request primitive is present, the originator sends an ADDBA Request frame that includes a GCR Group Address element. All DMG STAs are capable of participating in the block ack mechanism.
- c) If an ADDBA Response frame is received with the matching dialog token and the TID and with a status code equal to SUCCESS, the STA has established a block ack mechanism with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive indicating the successful completion of the Block Ack setup.
- d) If an ADDBA Response frame is received with the matching dialog token and the TID and with a status code not equal to SUCCESS, the STA has not established a block ack mechanism with the recipient STA; and the MLME shall issue an MLME-ADDBA.confirm primitive indicating the failure of the Block Ack setup.

11.5.2.3 Procedure at the recipient

A recipient shall operate as follows in order to support Block Ack initialization and modification:

- a) When an ADDBA Request frame is received from another STA, the MLME shall issue an MLME-ADDBA.indication primitive.
- b) Upon receipt of the MLME-ADDBA.response primitive, the STA shall respond by an ADDBA Response frame with a result code as defined in 9.6.5.3.
 - 1) If the result code is SUCCESS, the block ack agreement is considered to be established with the originator. Contained in the frame are the type of Block Ack and the number of buffers that have been allocated for the support of this block.
 - 2) If the result code is REFUSED, the block ack agreement is not considered to have been established.

The encoding of ResultCode values to Status Code field values is defined in Table 9-46.

11.5.2.4 Procedure common to both originator and recipient

Once a block ack agreement has been successfully established between two STAs, the type of agreement thus established is dependent on the capabilities of the STAs and the contents of the ADDBA Request and ADDBA Response frames used to establish this agreement as defined in Table 11-4 for non-DMG STAs and in Table 11-5 for DMG STAs.

Table 11-4—Types of block ack agreement based on capabilities and ADDBA conditions for non-DMG STAs

| Capabilities condition | ADDBA condition | Type of block ack agreement |
|---|--------------------------------------|-----------------------------|
| One or both of the STA are non-HT. See NOTE 1. | Block Ack Policy subfield equal to 1 | Immediate |
| | Block Ack Policy subfield equal to 0 | Delayed |
| Both STAs are HT STAs. | Block Ack Policy subfield equal to 1 | HT-immediate |
| Both STAs are HT STAs, and both of the STAs set the HT-delayed Block Ack subfield of the HT Capabilities element to 1. | Block Ack Policy subfield equal to 0 | HT-delayed See NOTE 2. |
| Both STAs are HT STAs, and at least one of the STAs sets the HT-delayed Block Ack subfield of the HT Capabilities element to 0. | Block Ack Policy subfield equal to 0 | Delayed |
| Both STAs are robust AV streaming STAs, and the agreement was established using ADDBA Request/Response frames that included GCR Group Address elements. | Block Ack Policy subfield equal to 1 | GCR Block Ack |
| NOTE 1—Non-HT block ack agreement is obsolete. Support for this mechanism might be removed in a later revision of the standard. | | |
| NOTE 2—HT-delayed block ack agreement is obsolete. Support for this mechanism might be removed in a later revision of the standard. | | |

NOTE—If the BlockAckReq and BlockAck variant is Extended Compressed and the Type of block ack agreement is HT-immediate, use of the RBUFCAP field is implementation dependent.

Table 11-5—Types of block ack agreement based on capabilities and ADDBA conditions for DMG STAs

| Capabilities condition | ADDBA condition | Type of BlockAckReq and BlockAck variant | Type of block ack agreement |
|---|------------------------------------|--|-----------------------------|
| Both STAs have the BlockAck with Flow Control field in the DMG Capabilities element equal to 1. | Block Ack Policy subfield set to 0 | Compressed | HT-immediate |
| At least one of the STAs has the BlockAck with Flow Control field in the DMG Capabilities element equal to 0. | Block Ack Policy subfield set to 0 | Compressed | HT-immediate |
| At least one of the STAs has the BlockAck with Flow Control field in the DMG Capabilities element equal to 0. | Block Ack Policy subfield set to 1 | Extended Compressed | HT-immediate |
| Both STAs have the BlockAck with Flow Control field in the DMG Capabilities element equal to 1. | Block Ack Policy subfield set to 1 | Extended Compressed | HT-immediate + flow control |

11.5.3 Teardown of the block ack mechanism

11.5.3.1 General

The procedure at the two STAs is described in 11.5.3.2 and 11.5.3.3 and illustrated in Figure 11-23.

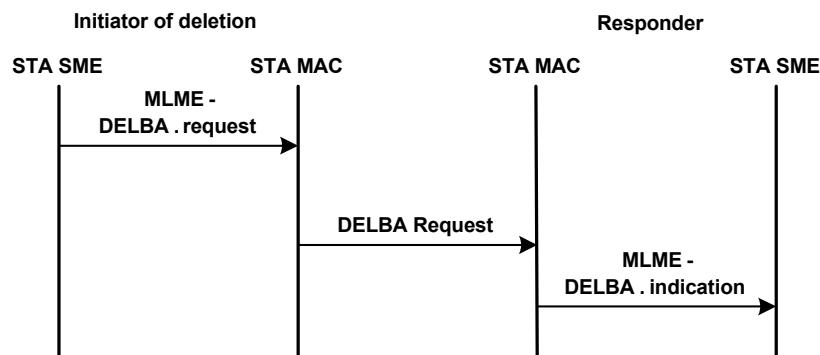

Figure 11-23—Block ack deletion

11.5.3.2 Procedure at the initiator of the block ack teardown

Upon receipt of an MLME-DELBA.request primitive, the MLME shall tear down the block ack by transmitting a DELBA frame.

The encoding of ReasonCode values to Reason Code field (see 9.4.1.7) values is defined in Table 9-45.

11.5.3.3 Procedure at the recipient of the DELBA frame

A STA shall issue an MLME-DELBA.indication primitive with the parameter ReasonCode having a value of REQUESTED when a DELBA frame is received.

11.5.4 Error recovery upon a peer failure

Every STA shall maintain an inactivity timer for every negotiated block ack setup, unless the block ack agreement is set up for a GCR group address. The inactivity timer at a recipient is reset when MPDUs corresponding to the TID for which the block ack policy is set are received and the Ack Policy subfield in the QoS Control field of that MPDU header is Block Ack or Implicit Block Ack Request. The inactivity timer is not reset when MPDUs corresponding to other TIDs are received. The inactivity timer at the recipient is also reset when a BlockAckReq frame corresponding to the TID for which the block ack policy is set is received. The inactivity timer at the originator is reset when a BlockAck frame corresponding to the TID for which the block ack policy is set is received. When a timeout of BlockAckTimeout is detected, the STA shall send a DELBA frame to the peer STA with the Reason Code field set to TIMEOUT and shall issue an MLME-DELBA.indication primitive with the ReasonCode parameter having a value of TIMEOUT. The procedure is illustrated in Figure 11-24.

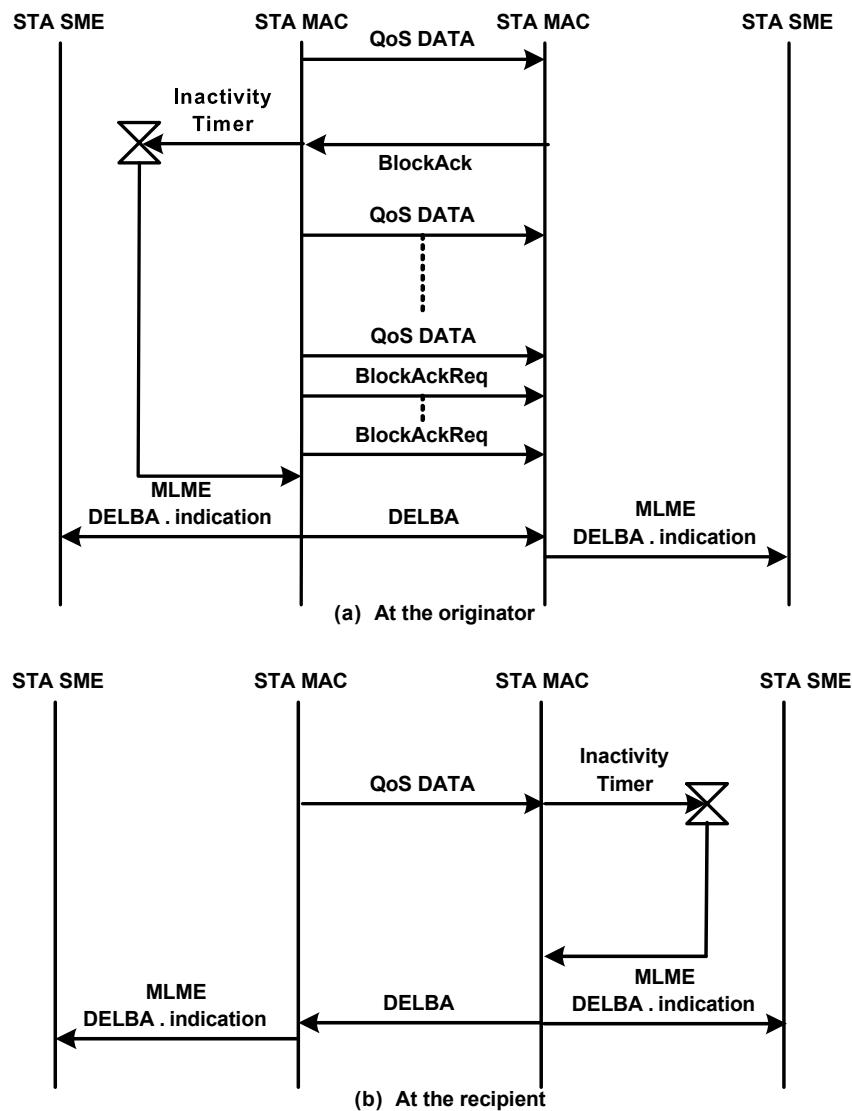

Figure 11-24—Error recovery by the receiver upon a peer failure

When a recipient does not have an active block ack for a TID, but receives Data frames with the Ack Policy subfield equal to Block Ack, it shall discard them and shall send a DELBA frame within its own TXOP. If such a STA receives a BlockAckReq frame, it may respond with an Ack frame and shall respond with a DELBA frame within its own TXOP. The originator may attempt to set up the use of block ack or may send the MPDUs using an alternative acknowledgment mechanism. When the recipient transmits a DELBA frame, it shall set the last sequence number received value to the sequence number of the last received MPDU, regardless of the acknowledgment policy used in that frame. When the originator receives a DELBA frame, it shall

- a) Discard any MPDU that has been transmitted and not acknowledged, with the possible exception if it was the last MPDU to be sent and it was not a retransmission, and
- b) Set the sequence number to either that of the last MPDU that is sent if it intends to retransmit or one beyond the last MPDU sent.

11.6 Higher layer timer synchronization

11.6.1 Introduction

Higher layer timer synchronization is beyond the scope of this standard. However, explanation of how the constructs in this standard might be used to support such capabilities might be useful to the designer.

One way to accomplish synchronization across a BSS is by multicasting synchronization (Sync) packets from the higher layers containing a time stamp and a sequence number. These packets would be opaque to the MAC and would be transported in the same way as any other MSDU (most likely addressed to the group address). Sync packets would be treated as a type of management packet by the higher layers. The time stamp in the Sync packet would contain the higher layer clock value at the time when the previous Sync packet was transmitted. The sequence number parameter has a value equal to the sequence number of the MSDU in which the time stamp is provided.

The reason the packet would contain the time stamp for the previous Sync packet (rather than the current packet) is that hardware and layering constraints would prohibit the ability to provide a time stamp for the exact instant the current packet is transmitted within that packet. However, an MLME-HL-SYNC.indication primitive allows the transmitting STA to know exactly when each Sync packet is transmitted. A receiving STA might note the time when each Sync packet is received as well as the sequence number for that frame. The receiving STA would save this receive time indication for each packet along with its sequence number and compare the indication of the previously received Sync packet to the time stamp in the most currently received packet. This comparison allows the STA to compute an offset, which can be used to adjust its time reference to match that of the synchronization source. A check of the sequence number verifies that the correct packet is being used for time stamp comparison. It is possible a packet is lost; in this case, the received time stamp for the lost packet should be discarded.

The last symbol of the Sync frame is indicated by the PHY using the PHY-TXEND.confirm and PHY-RXEND.indication primitives in the transmitter and receiver of the Sync frame, respectively. Practical limits on the coincidence of this indication and the last symbol of the Sync frame are implementation dependent. The accuracy of this technique also depends on the propagation delay between the source and receiving channel. However, both the time difference (between the PHY indication and the last symbol of the Sync frame) and the propagation delay can be considered as fixed-delay components. Therefore, they contribute only to the fixed time difference between the transmitter and receiver STAs' clocks and do not contribute to jitter. An implementation dependent scheme might be used to cancel or minimize this fixed time difference.

The Sync frame may also be relayed through the AP. In this case, the STA that generates the time stamps notes the reception of the group addressed Sync frame from the AP as the indication to save the higher clock value for the next Sync frame. Receiving STAs would also similarly note the time when each Sync packet is

received from the AP. The sequence number would include a value corresponding to the frame received from the AP.

This is an example implementation using the higher layer timer synchronization feature. Other implementations are possible.

11.6.2 Procedure at the STA

In order to determine whether to provide an MLME-HL-SYNC.indication primitive for a particular Data frame, a MAC that supports MLME-HL-SYNC primitives compares the Address 1 field in a Data frame's MAC header to a list of group addresses previously registered by an MLME-HL-SYNC.request primitive. If the MAC and the transmitter of the Sync frame are collocated within the same STA, the MLME-HL-SYNC.indication primitive shall occur when the last symbol of the PPDU carrying a matching Data frame is transmitted. Otherwise, the indication shall occur when the last symbol of the PPDU carrying the matching Data frame is received. In both cases, the MLME-HL-SYNC.indication primitive provided is simultaneous (within implementation dependent delay bounds) with the indication provided to other STAs within the BSS for the same Data frame.

11.7 DLS operation

11.7.1 General

The STSL mechanism is obsolete. Consequently, the DLS protocol might be removed in a later revision of the standard.

DLS is a protocol that enables a STA in an infrastructure network to transmit frames directly to another STA in the same infrastructure network. The need for this protocol is motivated by the fact that the intended recipient may be in PS mode, in which case it can be awakened only by the AP. The second feature of DLS is to exchange rate set and other information between the sender and the receiver.

A DMG STA shall not use the DLS protocol.

This protocol prohibits the STAs going into PS mode for the duration of the direct stream as long as there is an active DLS between the two STAs.

DLS does not apply in an IBSS, where frames are always sent directly from one STA to another. DLS does not apply in an MBSS, because frames in an MBSS are always sent directly from one mesh STA to another.

The handshake involved in the setup is illustrated in Figure 11-25.

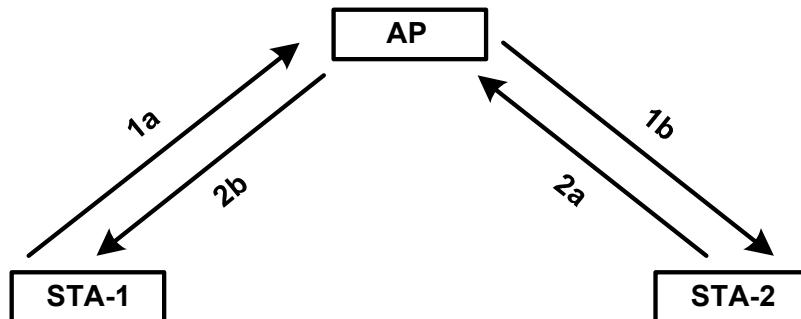

Figure 11-25—The four steps involved in direct-link handshake

The handshake involves the following steps:

- a) A STA, STA-1, that intends to exchange frames directly with another non-AP STA and dot11DLSAllowed is true, STA-2, invokes DLS and sends a DLS Request frame to the AP (step 1a in Figure 11-25). This request contains the rate set, capabilities of STA-1, and the MAC addresses of STA-1 and STA-2. If STA-1 is an HT STA, this request also contains the HT capabilities of STA-1. If STA-1 is a VHT STA, this response also contains a VHT Capabilities element representing the VHT capabilities of STA-1.
- b) If STA-2 is associated in the BSS, direct streams are allowed in the policy of the BSS (as determined by dot11DLSAllowedInQBSS), and STA-2 is indeed a QoS STA, then the AP forwards the DLS Request frame, independently of whether the AP is capable of decoding all of the fields in the body of the frame, to the recipient, STA-2 (step 1b in Figure 11-25).
- c) If STA-2 has dot11DLSAllowed true and accepts the direct stream, it sends a DLS Response frame to the AP (step 2a in Figure 11-25), which contains the rate set, (extended) capabilities of STA-2, and the MAC addresses of STA-1 and STA-2. If STA-2 is an HT STA, this response also contains an HT Capabilities element representing the HT capabilities of STA-2. If STA-2 is a VHT STA, this response also contains a VHT Capabilities element representing the VHT capabilities of STA-2.
- d) The AP forwards the DLS Response frame to STA-1 (step 2b in Figure 11-25), independently of whether the AP is capable of decoding all of the fields in the body of the frame.
- e) If the DLS Response frame contained a status code of SUCCESS, the direct link becomes active and frames may be sent from STA-1 to STA-2 and from STA-2 to STA-1.

When a STA transitions to a different AP after a DLS is set up, the DLS shall be torn down as described in 11.7.5.

11.7.2 DLS procedures

11.7.2.1 General

The DLS message flow is illustrated in Figure 11-26.

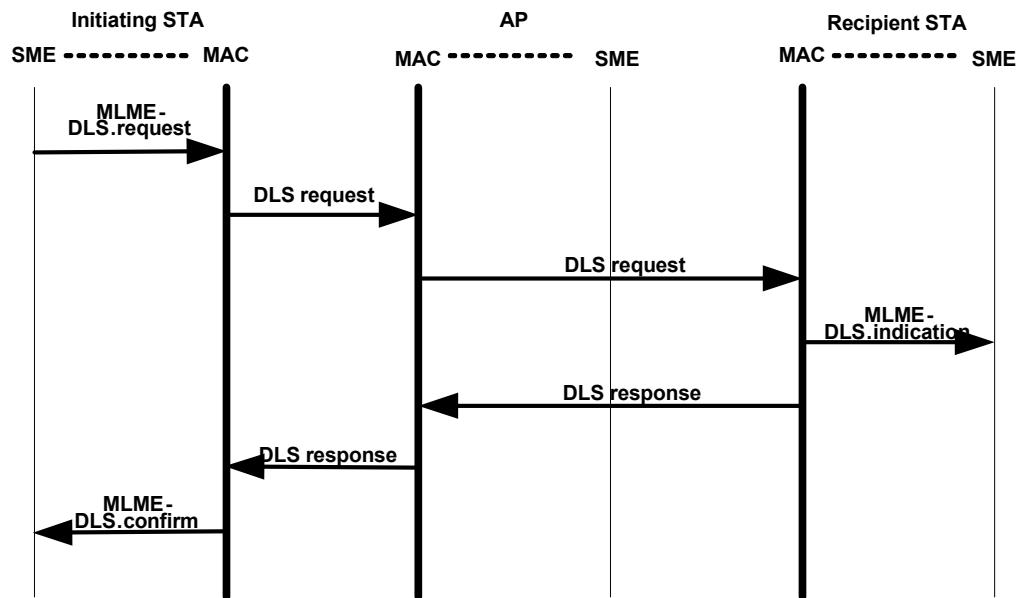

Figure 11-26—DLS message flow

11.7.2.2 Setup procedure at the QoS STA

A STA shall maintain a list of all STAs with which a direct link has been established.

Upon receipt of an MLME-DLS.request primitive from the SME, the STA shall do one of the following actions:

- Issue an MLME-DLS.confirm primitive with a result code of SUCCESS if the peer MAC address of MLME-DLS.request primitive is in the list of STAs with which direct link has been established; or
- Initiate the setup of the direct link by sending the DLS Request frame to the AP (step 1a in Figure 11-25).

Upon receipt of the DLS Request frame from the AP (step 1b in Figure 11-25), the MLME shall send to the AP a DLS Response frame (step 2a in Figure 11-25) with a result code of

- SUCCESS if the STA is willing to participate in the direct link with the source STA. The STA shall also issue an MLME-DLS.indication primitive to the SME and shall add the source STA to the list of the STAs, if not already present, with which direct link has been established.
- REFUSED if the STA is not willing to participate in the direct link.

Upon receipt of the DLS Response frame from the AP (step 2b in Figure 11-25), the STA shall issue an MLME-DLS.confirm primitive.

- If the result code is SUCCESS, the direct link is considered to be established with the destination STA in the DLS Response frame, and the MAC shall add the destination STA to the list of STAs with which direct link has been established.
- If the result code is REFUSED, the direct links is not considered to have been established.

11.7.2.3 Setup procedure at the AP

Upon receipt of the DLS Request frame (step 1a in Figure 11-25), the AP shall

- Send DLS Response frame to the STA that sent the DLS Request frame with a result code of Not Allowed in the BSS, if direct links are not allowed in the BSS (step 2b in Figure 11-25), or for the AP with dot11SSPNInterfaceActivated equal to true with a result code of Not Allowed by SSP if the dot11NonAPStationAuthDls in either of the non-AP STA's dot11InterworkingTable is false.
- Send DLS Response frame to the STA that sent the DLS Request frame with a result code of Not Present, if the destination STA is not present in the BSS (step 2b in Figure 11-25).
- Send DLS Response frame to the STA that sent the DLS Request frame with a result code of Not a QoS STA, if the destination STA does not have QoS facility (step 2b in Figure 11-25).
- Send the DLS Request frame, with all fields having the same value as the DLS Request frame received by the AP, to the destination STA (step 1b in Figure 11-25), independently of whether the AP is capable of decoding all of the fields in the body of the frame.

Upon receipt of the DLS Response frame from a STA (step 2a in Figure 11-25), the AP shall send DLS Response frame to the source STA (step 2b in Figure 11-25).

The mapping of Status Code field values to ResultCode parameter values in an MLME-DLS.confirm primitive is defined in Table 9-46.

11.7.2.4 Operation of the DLS Timeout Value field

The DLS Timeout Value field within the DLS Request frame contains the duration, in seconds, after which the direct link is terminated, if there are no frame exchanges within this duration with the peer. A value of 0 implies that the direct link is never to be terminated based on a timeout.

11.7.3 Data transfer after setup

For each active direct link, a STA shall record the MAC and PHY features, rates, and MCSs that are supported by the other STA participating in the direct link, according to the Supported Rates and BSS Membership Selectors, Extended Supported Rates and BSS Membership Selectors, Capability Information, HT Capabilities, and VHT Capabilities fields within the DLS Request and DLS Response frames that were used to establish the direct link.

A STA transmitting frames within a direct link shall not transmit frames using features, rates, or MCSs that are not supported by the other STA in the direct link. After establishing protection as required by 10.26 or 10.3.2.8, STAs may use features, rates, or MCSs that are supported by both of the STAs in the direct link, even when the AP does not support those features, except for transmission of a 40 MHz mask PPDU, which is governed by the rules found in 11.16.4.

STAs participating in a direct link may set up a block ack agreement, if needed. The STAs may set up TSSs with the HC to provide enough bandwidth or use polled TXOPs for data transfer. A protective mechanism (such as transmitting using HCCA, RTS/CTS, or the mechanism described in 10.26) should be used to reduce the probability of other STAs interfering with the direct-link transmissions.

11.7.4 DLS teardown

11.7.4.1 General

The DLS teardown procedure is divided into STA-initiated and AP-initiated DLS teardown. The STA-initiated DLS teardown message flow is illustrated in Figure 11-27.

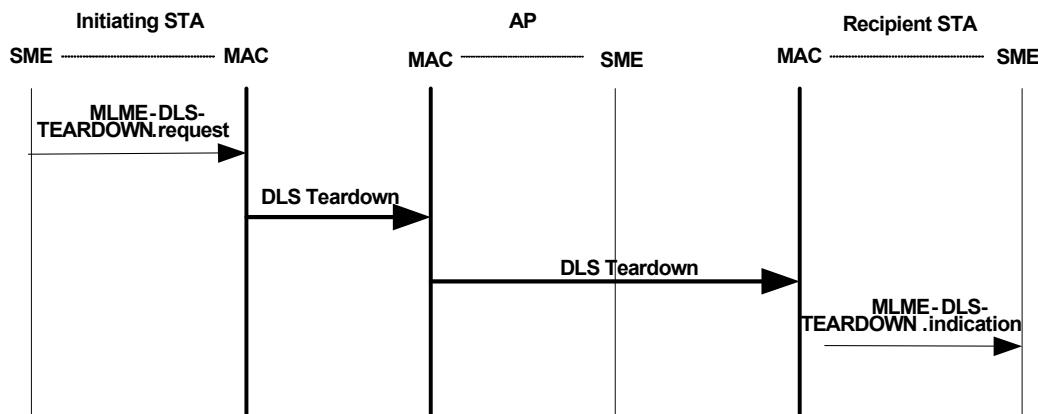

Figure 11-27—STA-initiated DLS teardown message flow

11.7.4.2 STA-initiated DLS teardown procedure

Upon receipt of MLME-DLS-TEARDOWN.request primitive from the SME, the STA shall initiate the teardown of the direct link by sending the DLS Teardown frame to the AP. The applicable values of ReasonCode are defined in Table 11-6. The encoding of the Reason Code field is defined in Table 9-45.

Upon receipt of the DLS Teardown frame (from the AP), the STA shall issue an MLME-DLS-TEARDOWN.indication primitive to the SME and shall delete the STA from the list of the STAs with which direct link has been established.

Table 11-6—ReasonCode values for DLS teardown

| ReasonCode | Applicable at |
|------------------|-------------------|
| STA_LEAVEING | Non-AP STA |
| END_DLS | Non-AP STA |
| UNKNOWN_DLS | Non-AP STA |
| TIMEOUT | Non-AP STA |
| PEERKEY_MISMATCH | AP |
| PEER_INITIATED | AP and Non-AP STA |
| AP_INITIATED | Non-AP STA |

The DLS teardown procedure shall apply to a specific DLS session, as each STA may have multiple simultaneous DLS sessions with other STAs.

Prior to disassociation/deauthentication from the AP, the STA (STA1) shall initiate the teardown of any direct links it has by sending a DLS Teardown frame to the AP. If the DLS Teardown frame's Max Retry Limit was reached with no response from the AP, the STA shall send a DLS Teardown frame to its peer DLS STA (STA2).

A recipient STA (STA2), on receipt of a DLS Teardown frame with ReasonCode equal to PEER_INITIATED (from STA1), shall send a DLS Teardown frame to the AP with ReasonCode set to PEER_INITIATED.

An AP that receives a DLS Teardown frame with ReasonCode equal to PEER_INITIATED should send a DLS Teardown frame to any STAs that have a DLS link established with STA1.

NOTE—The failed STA can reestablish its DLS link according to 11.7.

11.7.4.3 Teardown procedure at the AP

Upon receipt of the DLS Teardown frame from a STA, the AP shall send a DLS Teardown frame to the destination STA.

Upon receipt of MLME-DLS-TEARDOWN.request primitive from the SME, the AP shall announce the tearing down of the direct link by sending the DLS Teardown frame to the two STAs using the direct link. The only applicable values of the ReasonCode are PEERKEY_MISMATCH and STA_LEAVEING. The encoding to Reason Code field values is defined in Table 11-6.

11.7.4.4 AP-initiated DLS teardown procedure

The AP-initiated DLS teardown procedure may be used when the STA is unable to initiate the DLS teardown. The AP should initiate a DLS teardown procedure when the AP detects that either end of a DLS link has left the BSS without teardown of the DLS link, e.g., through receipt of a Deauthentication frame or receipt of a Disassociation frame.

If there are one or more STAs with open DLS connections with the STA being removed, the AP shall send a DLS Teardown frame to each such STA with ReasonCode AP_INITIATED.

NOTE—The AP can also initiate DLS teardown for implementation dependent reasons.

11.7.5 Error recovery upon a peer failure

Every STA shall maintain an inactivity timer for every negotiated direct link (i.e., STAs on both sides of the link maintain these timers). The DLS inactivity timer shall be reset for every successful frame transmission or reception for that direct link. The DLS timeout value is set according to the value of the DLS Timeout Value field in the DLS Request frame that initiated the direct link. If, for the period of time specified by the DLS timeout value, no frames are exchanged as part of the direct link, then the direct link becomes inactive. When the direct link becomes inactive due to timeout, the MLME issues an MLME-DLS-TEARDOWN.indication primitive to the SME and sends a DLS Teardown frame to the AP, with the peer MAC address as the destination MAC address and the reason code set to TIMEOUT. All frames shall henceforth be sent via the AP.

If there has been a TS setup for the data transfer, it is the responsibility of the STAs to renegotiate the parameters of the TSPEC with the HC.

When two STAs have set up a direct link, either STA may send DLS Request frames in order to update the DLS timeout value. If the updated DLS Request frame is accepted, both STAs initialize the timer to detect DLS timeout. Even if the updated DLS Request frame is not accepted, the original direct link remains active.

11.7.6 Secure DLS operation

PeerKey handshake, defined in 12.7.8, is used to establish the keys needed to enable secure DLS. The PeerKey message exchange shall start after the DLS establishment and completed prior to initiation of the DLS Data frame exchange.

The STKSA remains valid even if the STA disassociates from the originating AP, but the STKSA shall be deleted before a STA attempts another (re)association. If an AP transmits a Deauthenticate or Disassociate frame to a STA, the AP shall also initiate teardowns for any existing DLS. The DLS STKs shall be deleted when the DLS Teardown frames are sent or received.

11.8 TPC procedures

11.8.1 General

Regulations that apply to the 5 GHz band in most regulatory domains require RLANs operating in the 5 GHz band to use transmitter power control, involving specification of a regulatory maximum transmit power and a mitigation requirement for each allowed channel. This standard describes such a mechanism, referred to as *transmit power control (TPC)*.

This subclause describes TPC procedures intended to satisfy needs in many regulatory domains and other frequency bands. These procedures might be useful for other purposes (e.g., reduction of interference, range control, reduction of power consumption).

A STA shall use the TPC procedures defined in 11.8 if dot11SpectrumManagementRequired is true. dot11SpectrumManagementRequired shall be set to true when regulatory authorities require TPC. It may also be set to true in other circumstances. The TPC procedures provide for the following:

- Association of STAs with an AP or PCP in a BSS based on the STAs' power capability (see 11.8.2)
- Peering of mesh STAs based on the mesh STAs' power capability (see 11.8.3)
- Specification of regulatory and local maximum transmit power levels for the current channel (see 11.8.5)
- Selection of a transmit power for each transmission in a channel within constraints imposed by regulatory and local requirements (see 11.8.6)

- Adaptation of transmit power based on a range of information, including path loss and link margin estimates (see 11.8.7)

If `dot11SpectrumManagementRequired` is true, a non-DMG STA shall not join an infrastructure BSS, MBSS or IBSS unless the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames or in the Condensed Capability Information field in Measurement Pilot frames received from other STAs in the BSS, with the following exceptions:

- A STA may operate when the Spectrum Management bit is 0 if the STA determines that it is in a regulatory domain that does not require TPC or determines that it meets regulatory requirements even if TPC is not employed. Potential methods for determining the regulatory domain include receiving a country indication in the Beacon frame, Measurement Pilot frame, user confirmation, or configuration information within the device. Potential methods to meet regulations even if TPC is not employed include using a transmit power that is below the legal maximum (including any mitigation factor).
- A STA shall set `dot11SpectrumManagementRequired` to true before associating with a BSS in which the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames or in the Condensed Capability Information field in Measurement Pilot frames received from the BSS.
- An AP may allow association of devices that do not have the Spectrum Management bit equal to 1 in the Capability Information field in Association Request frames and Reassociation Request frames received from the STA to account for the existence of legacy devices that do not support TPC, but do meet regulatory requirements.

A mesh STA shall set `dot11SpectrumManagementRequired` to true before becoming a member of an MBSS in which the Spectrum Management bit is equal to 1 in the Capability Information field in Beacon frames and Probe Response frames received from the MBSS.

11.8.2 Association based on transmit power capability

A STA shall inform an AP or PCP of its minimum and maximum transmit power capability for the current channel when associating or reassociating, using a Power Capability element in (Re)Association Request frames.

An AP or PCP might use the minimum and maximum transmit power capability of associated STAs as an input into an algorithm used to determine the local transmit power constraint for any BSS it maintains. The specification of the algorithm is beyond the scope of this standard.

An AP or PCP may reject a (re)association request from a STA if it considers the STA's minimum or maximum transmit power capability to be unacceptable. For example, a STA's power capability might be unacceptable if it violates local regulatory constraints or increases the probability of hidden STAs by a significant degree. The criteria for accepting or rejecting a (re)association on the basis of transmit power capability are beyond the scope of this standard.

If a STA sends a Country element, a Power Constraint element, and a Transmit Power Envelope element, where the interpretation of the Maximum Transmit Power Level field in the Country element for a 20 MHz or 40 MHz Subband Triplet field is the same as the Local Maximum Transmit Power Unit Interpretation subfield, then at least one of local power constraints indicated by the Local Maximum Transmit Power For 20 MHz and Local Maximum Transmit Power For 40 MHz fields in the Transmit Power Envelope element shall be the same as the indicated local power constraint expressed by the combination of Country element and Power Constraint element.

NOTE—An example of the interpretation of the Maximum Transmit Power Level field in the Country element for a 20 MHz or 40 MHz Subband Triplet field being the same as the Local Maximum Transmit Power Unit Interpretation subfield is when both are EIRP.

11.8.3 Peering based on transmit power capability

A mesh STA shall provide a candidate peer mesh STA with its minimum and maximum transmit power capability for the current channel when becoming a member of an MBSS, using a Power Capability element in Mesh Peering Open frames.

A mesh STA may use the minimum and maximum transmit power capability of a neighbor peer mesh STA as an input into the algorithm used to determine the local transmit power constraint. The specification of the algorithm is beyond the scope of this standard.

A mesh STA may reject a Mesh Peering Open request from a candidate mesh STA if it considers the candidate mesh STA's minimum or maximum transmit power capability to be unacceptable. For example, a candidate mesh STA's power capability might be unacceptable if it violates local regulatory constraints. The criteria for establishing or rejecting a Mesh Peering Open request on the basis of transmit power capability are beyond the scope of this standard.

If a STA sends a Country element, a Power Constraint element, and a Transmit Power Envelope element, where the interpretation of the Maximum Transmit Power Level field in the Country element for a 20 MHz or 40 MHz Subband Triplet field is the same as the Local Maximum Transmit Power Unit Interpretation subfield, then at least one of the local power constraints indicated by a) the Local Maximum Transmit Power For 20 MHz field or b) Local Maximum Transmit Power For 40 MHz field in the Transmit Power Envelope element shall be the same as the indicated local power constraint expressed by the combination of Country element and Power Constraint element.

11.8.4 Interpretation of transmit power capability

As regards the units of the Minimum Transmit Power Capability and Maximum Transmit Power Capability fields within the Power Capability element sent in a STA's (Re)Association Request frame to an AP, if all of the following apply

- The STA is extended spectrum management capable.
- The STA has dot11SpectrumManagementRequired or dot11RadioMeasurementActivated equal to true.
- A Beacon or Probe Response frame has been received from the AP by the STA.
- The Beacon or Probe Response frame includes one or more Transmit Power Envelope elements.

then

- The units shall be interpreted according to the Local Maximum Transmit Power Unit Interpretation subfield in the Transmit Power Information field in the Transmit Power Envelope element (see 9.4.2.162) sent in the most recently received Beacon or Probe Response frame.

otherwise

- The units shall be interpreted as EIRP.

If the Beacon or Probe Response frame most recently received from a neighbor mesh STA by a mesh STA that is extended spectrum management capable and that has dot11SpectrumManagementRequired or dot11RadioMeasurementActivated equal to true includes one or more Transmit Power Envelope elements, then the units of the Minimum Transmit Power Capability and Maximum Transmit Power Capability fields within the Power Capability element sent in the Mesh Peering Open frame to the neighbor mesh STA shall be interpreted according to the Local Maximum Transmit Power Unit Interpretation subfield in the Transmit Power Information field in the Transmit Power Envelope element (see 9.4.2.162) sent in the most recently received Beacon or Probe Response frame. Otherwise, the units of the Minimum Transmit Power Capability

and Maximum Transmit Power Capability fields within the Power Capability element sent in the mesh STA's Mesh Peering Open frame to the neighbor mesh STA shall be interpreted as EIRP.

11.8.5 Specification of regulatory and local maximum transmit power levels

A STA shall determine a regulatory maximum transmit power for the current channel by selecting the minimum of the following:

- Any regulatory maximum transmit power received in a Country element from the AP in its BSS, PCP in its PBSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS
- Any regulatory maximum transmit power for the channel in the current regulatory domain known by the STA from other sources

A STA shall determine a local maximum transmit power for the current channel by selecting the minimum of the following:

- Unless the STA is extended spectrum management capable and has received a Transmit Power Envelope element for a channel width of 20 MHz and 40 MHz, any local maximum transmit power received in the combination of a Country element and a Power Constraint element from the AP in its BSS, PCP in its PBSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS
- If the STA is extended spectrum management capable, any local maximum transmit power received in a Transmit Power Envelope element from the AP in its BSS, another STA in its IBSS, or a neighbor peer mesh STA in its MBSS
- Any local maximum transmit power for the channel regulatory domain known by the STA from other sources

The Local Power Constraint field of any transmitted Power Constraint element and each Local Maximum Transmit Power For X MHz field (where $X = 20, 40, 80$, or $160/80+80$) in the Transmit Power Envelope element shall each be set to its respective value that allows the mitigation requirements to be satisfied in the current channel.

NOTE—The local maximum transmit power for the channel needs to meet the mitigation requirements for the channel in the current regulatory domain. The conservative approach is to set the local maximum transmit power level equal to the regulatory maximum transmit power level minus the mitigation requirement. However, it might be possible to satisfy the mitigation requirement using a higher local maximum transmit power level. A lower local maximum transmit power level might be used for other purposes (e.g., range control, reduction of interference).

The regulatory and local maximum transmit powers may change in a STA during the life of an infrastructure BSS and an MBSS. However, network stability needs to be considered when deciding how often or by how much these maximums are changed. The regulatory and local maximum transmit powers shall not change during the life of an IBSS.

An AP, IBSS STA, or mesh STA shall advertise the regulatory maximum transmit power for that STA's operating channel in Beacon frames and Probe Response frames using a Country element. An AP, IBSS STA or mesh STA shall advertise the local maximum transmit power for that STA's operating channel in Beacon frames and Probe Response frames using the combination of a Country element and a Power Constraint element.

If an AP, IBSS STA, or mesh STA is extended spectrum management capable, it shall advertise the local maximum transmit power for that STA's operating channel in Beacon frames and Probe Response frames using one Transmit Power Envelope element for each distinct value of the Local Maximum Transmit Power Unit Interpretation subfield that is supported by the BSS, IBSS, or MBSS, respectively. Each Transmit Power Envelope element shall include a local power constraint for all channel widths supported by the BSS.

STAs that are extended spectrum management capable and have dot11RadioMeasurementActivated equal to true should be able to reduce their EIRP to 0 dBm.

NOTE—When the local maximum transmit power is set by an AP for radio resource management, a typical low value for the local power constraint is 0 dBm. A STA that cannot reduce its transmit power to this level or below will not be able to associate to the AP.

The PCP in a PBSS shall advertise both the regulatory maximum transmit power and the local maximum transmit power for its operating channel in Announce and Probe Response frames (using a Country element for the regulatory maximum and a combination of a Country element and a Power Constraint element for the local maximum). In addition, it should advertise both regulatory and local maximum transmit power in DMG Beacon frames.

When dot11SpectrumManagementRequired is false and dot11RadioMeasurementActivated is true, an AP or a PCP may include a Power Constraint element and a Transmit Power Envelope element in Beacon, DMG Beacon, Announce, and Probe Response frames.

11.8.6 Transmit power selection

A STA may select any transmit power for transmissions in a channel within the following constraints:

- A STA shall determine a regulatory maximum transmit power and a local maximum transmit power for a channel in the current regulatory domain before transmitting in the channel.
- An AP shall use a transmit power less than or equal to the regulatory maximum transmit power level for the channel. The AP shall also meet any regulatory mitigation requirement.
- A non-AP STA shall use a transmit power less than or equal to the local maximum transmit power level for the channel.

11.8.7 Transmit power adaptation

A STA may use any criteria, and in particular any path loss and link margin estimates, to dynamically adapt the transmit power for transmissions of an MPDU to another STA. The adaptation methods or criteria are beyond the scope of this standard.

A STA may use a TPC Request frame to request another STA to respond with a TPC Report frame reporting link margin and transmit power information. A STA that receives a TPC Request frame shall respond with a TPC Report frame that contains a TPC Report element in which the Transmit Power field indicates the power used to transmit the response and the Link Margin field indicates the estimated link margin. A DMG STA may also use the link measurement procedure and the DMG Link Margin element to exchange TPC information.

An AP, PCP, or IBSS STA shall autonomously include a TPC Report element with the Link Margin field set to 0 in Beacon frames, DMG Beacon frames, Announce frames, or Probe Response frames.

11.9 DFS procedures

11.9.1 General

Regulations that apply to the 5 GHz band in most regulatory domains require RLANs operating in the 5 GHz band to implement a mechanism to avoid co-channel operation with radar systems and to uniformly utilize available channels. This standard describes such a mechanism, referred to as *dynamic frequency selection (DFS)*.

This subclause describes DFS procedures that can be used to satisfy these and similar future regulatory requirements. The procedures might also satisfy comparable needs in other frequency bands and might be useful for other purposes. For example, some of the procedures described in this subclause could be used for channel selection in a DMG BSS.

A STA shall use the DFS procedures defined in 11.9.1 to 11.9.9 if `dot11SpectrumManagementRequired` is true.

A STA shall use the DFS procedures defined in 11.9.10 if `dot11SpectrumManagementRequired` and `dot11FutureChannelGuidanceActivated` are true.

Attribute `dot11SpectrumManagementRequired` shall be set to true when regulatory authorities require DFS. It may also be set to true in other circumstances. The DFS procedures provide for the following:

- Associating STAs with an AP based on the STAs' supported channels (see 11.9.2)
- Quieting the current channel so it can be tested for the presence of radar with less interference from other STAs (see 11.9.3)
- Testing channels for radar before using a channel and while operating in a channel (see 11.9.4)
- Discontinuing operations after detecting radar in the current channel to avoid further interference with radar (see 11.9.5)
- Detecting radar in the current and other channels, based on regulatory requirements (see 11.9.6)
- Requesting and reporting measurements in the current and other channels (see 11.9.7)
- Selecting and advertising a new channel to assist the migration of a BSS after radar is detected (see 11.9.8)
- Guiding STAs about the likely future channel should the AP leave this channel (see 11.9.10).

In a DMG BSS, the following DFS procedures apply:

- Associating a STA with an AP or a PCP based on the STA's supported channels (see 11.9.2)
- Quieting the current channel so it can be tested for interference with less interference from associated STAs (see 11.9.3)
- Requesting and reporting measurements in the current and other channels (see 11.9.7)
- Selecting and advertising a new channel to assist the migration of an infrastructure BSS, IBSS, or PBSS (see 11.9.8)

For the purposes of DFS in a non-DMG BSS, the following statements apply:

- A STA with `dot11SpectrumManagementRequired` true shall not operate in a BSS unless the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames received from other STAs in the BSS, with the following exception.
 - A STA may operate when the Spectrum Management bit is 0 if the STA determines that it is in a regulatory domain that does not require DFS or determines that it meets regulatory requirements even if DFS is not employed. Potential methods for determining the regulatory domain include receiving a country indication in the Beacon frame, user confirmation, or configuration information within the device. Potential methods to enable regulations to be met even if DFS is not employed include independently detecting radar and ceasing operation on channels on which radar is detected.
- A STA shall set `dot11SpectrumManagementRequired` to true before associating with an infrastructure BSS, IBSS, or MBSS in which the Spectrum Management bit is 1 in the Capability Information field in Beacon frames and Probe Response frames received from the infrastructure BSS, IBSS, or MBSS.
- An AP may allow association of devices that do not have the Spectrum Management bit equal to 1 in the Capability Information field in Association Request frames and Reassociation Request frames received from a STA to account for the existence of legacy devices that do not support DFS, but do meet regulatory requirements.

11.9.2 Association based on supported channels

11.9.2.1 Association based on supported channels in a non-DMG BSS

A STA shall provide an AP with a list of the channels in which the STA can operate when associating or reassociating by including a Supported Channels element in its (Re)Association Request frames.

An AP may use the supported channels list for associated STAs as an input into an algorithm used to select a new channel for the BSS. The specification of this algorithm is beyond the scope of this standard.

An AP may reject an (re)association request from a STA if it considers the STA's supported channel list to be unacceptable. For example, a STA's supported channel list might be unacceptable if it can operate only in a limited number of channels. The criteria for accepting or rejecting (re)associations are beyond the scope of this standard.

11.9.2.2 Providing supported channels upon association in a DMG BSS

An AP or PCP may advertise the regulatory domain in which it is located via a Country element in the DMG Beacon, Announce, or Information Response frames if dot11MultiDomainCapabilityActivated is true.

When it (re)associates, the STA shall provide to the AP or PCP a list of channels in which the STA can operate. The STA does this by including a Supported Channels element in the Information Request or (Re)Association frames that it transmits. An AP or PCP can use the supported channels list for associated STAs as an input into an algorithm used to select a new channel for the BSS. The specification of this algorithm is beyond the scope of this standard.

The AP or PCP may advertise the supported channels of associated STAs via an Information Response frame with Subject Address field set to the broadcast address and a Supported Channels element that lists the intersection of channels supported by STAs associated with the BSS, as indicated by their Supported Channels elements.

11.9.3 Quieting channels for testing

When the AP Quiet Mode field of a Quiet Channel element has the value 1, the Quiet Channel element is called a *mode set Quiet Channel element*.

An AP may schedule quiet intervals by transmitting one or more mode set Quiet Channel elements or one or more Quiet elements in Beacon frames and Probe Response frames.

A mesh STA may schedule quiet intervals by transmitting one or more Quiet elements in Beacon frames and Probe Response frames.

A non-VHT AP shall not transmit a Quiet Channel element. An AP shall not transmit a Quiet Channel element with the AP Quiet Mode field value equal to 0 in frames that do not include at least one Quiet element. An AP shall not transmit more than one Quiet Channel element with the AP Quiet Mode field equal to 0. An AP shall not transmit a Quiet Channel element if the BSS bandwidth is neither 160 MHz nor 80+80 MHz.

An AP may stop scheduling quiet intervals, or may transmit Quiet elements with changes in the Quiet Period, Quiet Duration and Quiet Offset fields, or may transmit mode set Quiet Channel elements. A mesh STA may stop scheduling quiet intervals, or may transmit Quiet elements with changes in the Quiet Period, Quiet Duration and Quiet Offset fields. Only the most recently received Beacon frame or Probe Response frame defines all future quiet intervals; therefore, all schedules for quiet intervals based on older Beacon frames or Probe Response frames shall be discarded.

An AP or PCP in a DMG BSS may measure one or more channels itself, or the AP or PCP may request associated non-AP and non-PCP STAs in the same BSS to measure one or more channels, either in a dedicated measurement interval or during normal operation. The AP or PCP in a DMG BSS may schedule a service period allocated to itself to quiet the associated STAs and use the self-allocated SP for measurement.

An IBSS STA may schedule quiet intervals only if it is the DFS owner. In order to set a quiet interval schedule, the STA transmits one or more Quiet elements in the first Beacon frame establishing the IBSS. All IBSS STAs shall continue these quiet interval schedules by including appropriate Quiet elements in any transmitted Beacon frames or Probe Response frames.

Multiple independent quiet intervals may be scheduled, so that not all quiet intervals have the same timing relationship to TBTT, by including multiple Quiet elements or, in an infrastructure BSS, mode set Quiet Channel elements in Beacon frames or Probe Response frames.

Control of the channel is lost at the start of a quiet interval, and the following quieting rules apply:

- The NAV is set by all of the non-VHT STAs in the BSS for the length of the quiet interval established by a Quiet element.
- The NAV is set by all of the VHT STAs in the BSS for the duration of the quiet interval established by a Quiet element if a Quiet Channel element was not sent or received with the Quiet element.
- A VHT STA in the BSS shall not transmit PPDUs that occupy the secondary 80 MHz channel or, in an infrastructure BSS, transmit PPDUs to the AP during the quiet interval established by a Quiet element if a Quiet Channel element with the AP Quiet Mode field equal to 0 was sent or received with the Quiet element.
- A VHT STA in an infrastructure BSS shall not transmit PPDUs that occupy the secondary 80 MHz channel during the quiet interval established by a Quiet Channel element with the AP Quiet Mode field in the Quiet Channel element equal to 1.
- Transmission by any non-VHT STA in the BSS of any MPDU and any associated acknowledgment within either the primary channel or the secondary channel (if present) shall complete before the start of the quiet interval.
- Transmission by any VHT STA in the BSS of any MPDU and any associated acknowledgment of the BSS shall complete before the start of the quiet interval established by a Quiet element if a Quiet Channel element was not sent or received with the Quiet element.
- Transmission by any VHT STA in the BSS of any PPDUs that occupy the secondary 80 MHz channel or, in an infrastructure BSS, are directed to the AP, and any associated acknowledgment of the BSS, shall complete before the start of the quiet interval established by a Quiet element if a Quiet Channel element with the AP Quiet Mode field equal to 0 was sent or received with the Quiet element.
- Transmission by any VHT STA in the infrastructure BSS of any PPDUs that occupy the secondary 80 MHz channel and any associated acknowledgment of the BSS shall complete before the start of the quiet interval established by a Quiet Channel element with the AP Quiet Mode field in the Quiet Channel element equal to 1.

Before starting transmission of an MPDU, a STA shall check if there is enough time for the exchange to complete within the time allowed by the quieting rules. If there is not enough time, the STA shall defer the transmission by selecting a random backoff time, using the present CW (without advancing to the next value in the series). The short retry counter and long retry counter for the MSDU or A-MSDU are not affected.

11.9.4 Testing channels for radar

A STA does not transmit in a channel unless the channel has been tested for the presence of radar transmissions according to regulatory requirements.

11.9.5 Discontinuing operations after detecting radar

If a STA is operating in a channel and detects radar operating in the channel or accepts that another STA has detected radar operating in the channel, then the STA discontinues transmissions according to regulatory requirements.

11.9.6 Detecting radar

The methods that satisfy regulatory requirements to detect radar transmissions are beyond the scope of this standard.

11.9.7 Requesting and reporting of measurements

The response to a Basic request is a Basic report. A STA in an infrastructure BSS or PBSS shall generate a Basic report in response to a Basic request if the request is received from the AP or PCP with which it is associated, except as specified in this subclause.

A STA may measure one or more channels itself or a STA may request other STAs in the same BSS to measure one or more channels on its behalf. These measurements may occur either during a quiet interval or during normal operation.

In order to request other STAs to measure one or more channels, a STA shall use a Measurement Request frame containing one or more Measurement Request elements. The measurement request may be sent to an individual or group destination address. Addressing requests to multiple STAs should be used with care to avoid a reply storm.

The measurement requests effectively allowed by these rules are shown in Table 11-7.

Table 11-7—Allowed measurement requests

| Service set | Source of request | Destination of request | Type of measurement request allowed |
|-------------|-------------------|------------------------|-------------------------------------|
| BSS | AP | STA | Individual or group |
| | STA | AP | Individual only |
| | STA | STA | None |
| IBSS, MBSS | STA | STA | Individual or group |
| PBSS | PCP | Non-PCP STA | Individual or group |
| | Non-PCP STA | PCP | Individual |
| | Non-PCP STA | Non-PCP STA | None |

A STA that successfully requests another STA to perform a measurement on another channel should not transmit MSDUs, A-MSDUs, or MMPDUs to that STA during the interval defined for the measurement plus any required channel switch intervals. In determining this period, a STA shall assume that any required channel switches take dot11ChannelSwitchTime per switch.

A STA that receives an individually addressed Measurement Request frame from a STA in its BSS shall parse the frame's Measurement Request elements in order, with measurements starting at the times specified by the Measurement Request elements.

Any result of a measurement request shall be returned without undue delay to the requesting STA in Measurement Report elements using one or more Measurement Report frames. The result may be the completed measurement or an indication that the STA is unable to complete the measurement request.

A STA shall report it is too late to undertake a measurement request if it receives the request after the specified starting time for the measurement.

A STA shall report it is refusing a measurement request if all of the following conditions exist:

- The STA is capable of undertaking a measurement request.
- The STA does not want to undertake the measurement request at this time.
- The measurement request is not mandatory.

NOTE—Measurements are specified as mandatory or optional in 9.4.2.21).

A STA shall report it is incapable of performing a measurement request if any of the following conditions exists:

- The STA is incapable of undertaking an optional measurement request.
- The STA does not support the channel specified in a mandatory measurement request.
- The STA does not support any requested parallel measurements in the same or different channels.

A Measurement Report frame shall contain the same value in its Dialog Token field as the value of the Dialog Token field in the corresponding Measurement Request frame, and each Measurement Report element shall contain the same value in its Measurement Token field as the value of the Measurement Token field in the corresponding Measurement Request element.

A STA may autonomously report measurements to another STA in its BSS by transmitting a Measurement Report frame that includes a Dialog Token field set to 0 and one or more Measurement Report elements. An IBSS STA may also autonomously report measurements to other STAs in the IBSS using the Channel Map field in the IBSS DFS element in a Beacon frame or Probe Response frame.

A STA may enable or disable measurement requests or autonomous measurement reports from another STA by transmitting Measurement Request elements with the Enable bit set to 1 and the Request bit and Report bit set to 0 or 1, as appropriate. These elements do not require a corresponding Measurement Report element in a Measurement Report frame. All measurement requests and reports shall be enabled by default. An AP or PCP may ignore a request to disable a mandatory measurement request. All other such requests shall be honored.

The measurement request and report procedures are defined in 11.11.

11.9.8 Selecting and advertising a new channel

11.9.8.1 General

A channel switch is an attempt to move a BSS to a new operating channel. It is an objective that disruption to the BSS be minimized in this process, although it should be recognized that a channel switch might not successfully move all STAs.

Two procedures are defined for switching channels: the channel switching procedure, which is defined in 11.9.8 and 11.9.9, and the extended channel switching procedure, which is defined in 11.10.

It should also be stressed that both the channel switching procedure and the extended channel switching procedure are distinct from the regulatory requirement to cease transmission on a particular channel in the presence of radar.

11.9.8.2 Selecting and advertising a new channel in a non-DMG infrastructure BSS

This subclause describes operation in an infrastructure BSS that is a non-DMG BSS. For a DMG infrastructure BSS, see 11.9.8.6.

The decision to switch to a new operating channel in an infrastructure BSS shall be made only by the AP. An AP may make use of the information in Supported Channel elements and the results of measurements undertaken by the AP and other STAs in the BSS to assist the selection of the new channel. The algorithm to choose a new channel is beyond the scope of this standard. The AP shall attempt to select a new channel that is supported by all associated STAs.

An AP shall inform associated STAs that the AP is moving to a new channel and shall maintain the association by advertising the switch using Channel Switch Announcement elements in Beacon frames, Probe Response frames, and Channel Switch Announcement frames until the intended channel switch time. The AP may force STAs in the BSS to stop transmissions until the channel switch takes place by setting the Channel Switch Mode field in the Channel Switch Announcement element to 1. The channel switch should be scheduled so that all STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Channel Switch Announcement element before the switch. The AP may send the Channel Switch Announcement frame in a BSS without performing a backoff, after determining the WM is idle for one PIFS (see 10.3.2.3).

If a Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 20 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element shall not be present in the same frame.

If a Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 40 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element shall also be present in the same frame if the STA sending the frame is extended spectrum management capable.

A Channel Switch Wrapper element shall not be included in Beacons and Probe Response frames if the element contains zero subelements.

A STA that receives a Channel Switch Announcement element may choose not to perform the specified switch, but to take alternative action. For example, it may choose to move to a different BSS.

A non-AP STA in an infrastructure BSS shall not transmit the Channel Switch Announcement element.

11.9.8.3 Selecting and advertising a new channel in an IBSS

DFS in an IBSS is complicated by the following:

- There is no central AP function for collating measurements or coordinating a channel switch. If STAs make independent decisions to switch channel in the presence of radar, there is a danger that all STAs announce switches to different channels if several of them detect the radar.
- There is no association protocol that can be used to
 - Exchange supported channel information
 - Determine membership of the IBSS at a given instant for requesting measurements.

- Beaconing is a shared process; therefore, there is no guarantee that a STA that has something to send (e.g., a channel switch message) will be the next STA to transmit a Beacon frame.
- A 20/40 MHz IBSS cannot be changed to a 20 MHz IBSS, and a 20 MHz IBSS cannot be changed to a 20/40 MHz IBSS.

The DFS owner service, IBSS DFS element, and Channel Switch Announcement frame address these complications:

- The DFS owner service provides a central point of coordination for a channel switch. It attempts to minimize the probability that multiple STAs concurrently decide to switch to different channels. The DFS Owner field and DFS Recovery Interval field in the IBSS DFS element support the DFS owner service.
- Each STA shall include a Channel Map field in the IBSS DFS elements that it transmits. The channel map communicates the STA-supported channel set and basic measurement reports for that STA.
- Each STA shall have the ability to send a Channel Switch Announcement element in a Management frame other than a Beacon frame or Probe Response frame.

The potential for hidden nodes within an IBSS means that an IBSS channel switching procedure might not move all STAs. In some regulatory domains, each STA in an IBSS is required by regulation to detect radar and cease transmission, after a required interval, on any channel on which the presence of radar is detected.

A STA at which an IBSS is started shall be a DFS owner in that IBSS. That STA shall include its MAC address in the DFS Owner field of the IBSS DFS element and DFS Recovery Interval field from the MLME.START.request primitive parameter. The purpose of the DFS owner is to coordinate a channel switch. All STAs in an IBSS shall have the ability to become DFS owner.

Each IBSS STA shall adopt the DFS Owner field and the DFS Recovery Interval field from any valid IBSS DFS element when the received frame contains a matching SSID and the value of the timestamp is later than the STA's TSF timer. The STA shall include the adopted values in the IBSS DFS elements it transmits. Because all IBSS STAs participate in sending Beacon frames, this process always, over a number of beacon intervals, results in a unified view of one DFS owner throughout the IBSS.

In order to attempt a channel switch using the DFS owner, a STA that detects radar shall broadcast one or more Measurement Report frames indicating the presence of the radar.

A DFS owner receiving a Measurement Report frame indicating the presence of radar in the current channel shall select and advertise a new operating channel (including the possibility of no change). The DFS owner may make use of information received in Channel Map fields and from measurements undertaken by other members of the IBSS to assist the selection of the new channel. The algorithm to choose a new channel is beyond the scope of this standard, but shall satisfy any regulatory requirements, including uniform spreading rules and channel testing rules. The DFS owner shall attempt to select a new channel that is supported by all members of the IBSS. Note that this process might be imperfect in that the DFS owner might have incomplete knowledge and there might not be a suitable channel.

The DFS owner shall attempt to make the members of the IBSS aware of the new operating channel by broadcasting at least one Channel Switch Announcement frame. The DFS owner may transmit the Channel Switch Announcement frame in an IBSS without performing a backoff, after determining that the WM is idle for one PIFS (see 10.3.2.3). The DFS owner shall also include the Channel Switch Announcement element in all Beacon frames, Probe Response frames, or Channel Switch Announcement frames until the intended channel switch time. A STA that receives a valid Channel Switch Announcement element that is not a superseded Channel Switch Announcement element (see 11.16.3.3) shall repeat this element in all Beacon frames and Probe Response frames that it transmits. The DFS owner may attempt to silence STAs in the IBSS until the channel switch takes place using the Channel Switch Mode field in the Channel Switch

Announcement element. If possible, the channel switch should be scheduled so that all STAs in the IBSS, including STAs in power save mode, have the opportunity to receive at least one Channel Switch Announcement element before the switch.

If a STA does not receive a valid Channel Switch Announcement element from the DFS owner within the DFS recovery time, then it shall enter DFS recovery mode. DFS recovery time is measured from the end of the frame that first announced radar presence, whether that frame was transmitted by the STA or received from another STA. In DFS recovery mode the STA shall assume the role of DFS owner, shall select a new operating channel, and shall advertise the new channel by transmitting a Channel Switch Announcement frame using the contention resolution algorithm defined for beacon transmission at TBTT in 11.1.3.5. The STA shall also include the Channel Switch Announcement element in all Beacon frames and Probe Response frames until the intended channel switch time. A STA that is not the DFS owner shall not initiate a channel switch.

If the STA receives a valid Channel Switch Announcement element that is not a superseded Channel Switch Announcement element (see 11.16.3.3 from another member of the IBSS, the STA shall leave DFS owner recovery mode prior to the channel switch and adopt the received channel switch information. If the Channel Switch Announcement element was in a Beacon frame or Probe Response frame, the STA shall also adopt the STA identified by the DFS owner address of the IBSS DFS element as the DFS owner. If the Channel Switch Announcement element was in a Channel Switch Announcement frame, the receiving STA shall adopt the STA that transmitted the frame as the DFS owner.

There are several circumstances when DFS owner recovery is needed (e.g., if the original DFS owner has left the network or if the original measurement report was not received by the initial DFS owner). Note that DFS owner recovery might temporarily give rise to more than one DFS owner in the IBSS. This risk is mitigated by the random nature of the IBSS DFS recovery mechanism. However, because all IBSS STAs participate in sending Beacon frames, over a number of beacon periods, there will be convergence from multiple DFS owners to one DFS owner.

11.9.8.4 MBSS channel switching

11.9.8.4.1 General

A mesh channel switch might be triggered by the need to avoid interference to a detected radar signal, or to reassign mesh STA channels to maintain MBSS connectivity.

A mesh STA may make use of the information in Supported Channel elements, Supported Operating Classes elements, and the results of measurements undertaken by the mesh STAs in the MBSS to assist the selection of the new channel. The algorithm for choosing a new channel is beyond the scope of this standard.

A 20/40 MHz MBSS may be changed to a 20 MHz MBSS and a 20 MHz MBSS may be changed to a 20/40 MHz MBSS.

When an MBSS switches from a 20 MHz MBSS to a 20/40 MHz MBSS or switches from a 20/40 MHz MBSS to a 20 MHz MBSS, a mesh STA might need to do path maintenance to find an optimized path.

11.9.8.4.2 Initiating MBSS channel switch

A mesh STA shall not initiate a new channel switch attempt if there is an ongoing channel switch attempt by this mesh STA.

A mesh STA shall inform each of the peer mesh STAs that the mesh STA is moving to a new channel while maintaining mesh peerings by including Channel Switch Announcement elements together with the Mesh Channel Switch Parameters element in all Beacon frames, Probe Response frames, and Channel Switch

Announcement frames that it transmits until the intended channel switch time. The channel switch should be scheduled so that all mesh STAs in the MBSS, including mesh STAs in power save mode, have the opportunity to receive at least one Channel Switch Announcement element before the switch.

The fields in the Channel Switch Announcement element are set as follows:

- The Channel Switch Count field shall be set to the time period until the mesh STA sending the Channel Switch Announcement element switches to the new channel.
- The Channel Switch Mode field is reserved.
- The New Channel Number field shall be set to the number of the channel to which the mesh STA is moving.

The fields in the Mesh Channel Switch Parameters element are set as follows:

- The Precedence Value field shall be set to a random value selected from a uniform distribution in the range 0 to 65 535.
- The mesh STA may force mesh STAs in the MBSS to stop transmissions of frames (except frames containing Channel Switch Announcement element) until the channel switch takes place by setting the Transmit Restrict subfield of the Flags field to 1.
- The Reason subfield in the Flags field shall be set to 1 to indicate that the content of the Reason Code field (as defined in Table 9-45) is valid. The Reason Code field shall be set to MESH-CHANNEL-SWITCH-REGULATORY-REQUIREMENTS when the channel switch is initiated to meet regulatory requirement; otherwise, the Reason Code field shall be set to MESH-CHANNEL-SWITCH-UNSPECIFIED.
- The Initiator subfield of the Flag field shall be set to 1.
- The Time To Live field should be set to the maximum number of hops (e.g., dot11MeshHWMPnetDiameter) for which this Channel Switch attempt is intended.

11.9.8.4.3 Processing channel switch announcement

Upon receipt of a Channel Switch Announcement frame or Extended Channel Switch Announcement frame, a mesh STA shall not accept and shall not process the received Channel Switch Announcement element or Extended Channel Switch Announcement element, if any of the following is true:

- The Mesh Channel Switch Parameters element is not present in the received frame containing the Channel Switch Announcement element or the Extended Channel Switch Announcement element.
- The Time To Live field in the received Mesh Channel Switch Parameters element is 0.
- A mesh channel switch is already running and the mesh STA has not yet moved into the new channel and/or operating class and the current precedence value is greater than or equal to the value of the received Precedence Value field.

A mesh STA that receives a Channel Switch Announcement element may choose not to perform the specified switch, but to take alternative action. For example, it may choose to move to a different MBSS.

When a mesh STA accepts a channel switch, it shall adopt the information received in the Channel Switch Announcement element and the Mesh Channel Switch Parameters element. The mesh STA shall schedule the channel switch according to this information. If the Time To Live field value in the received Mesh Channel Switch Parameters element is greater than 1, the mesh STA shall transmit a Channel Switch Announcement frame and shall include a Channel Switch Announcement element together with a Mesh Channel Switch Parameters element in the Beacon and Probe Response frames until the intended channel switch time. The Channel Switch Mode and New Channel Number fields in the transmitted Channel Switch Announcement element(s) are set to the same values as in the received Channel Switch Announcement element. The Channel Switch Count field is set to indicate the time remaining until the channel switch, as specified in 9.4.2.19. The Reason Code and Precedence Value fields in the transmitted Mesh Channel Switch Parameters element(s) are set to the same values as in the received Mesh Channel Switch Parameters

element. The Time to Live and Flags fields are set as specified in 9.4.2.103. The Time To Live field shall be set to the received Time To Live field minus 1. The Initiator field shall be set to 0. The Transmit Restrict field shall be set to 1 when the mesh STA requires neighboring mesh STAs not to transmit (until the scheduled channel switch occurs) further frames that do not contain the Channel Switch Announcement element on the current channel. The Transmit Restrict subfield shall be set to 0 otherwise.

It is possible that a channel switch is not successful in moving all of the mesh STAs in MBSS to the new operating channel. Transitioning to a new channel does not tear down mesh peerings and, as long as the mesh peers move to the new operating channel, their peerings are maintained in the new channel.

After moving into a new operating channel, the mesh STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time indicated by the NAVSyncDelay parameter from the most recent MLME-START.request primitive has transpired.

11.9.8.4.4 Channel switch across an operating class

When dot11OperatingClassesImplemented is true and the mesh STA is capable of operation in more than one operating class, the mesh STA shall include the Supported Operating Classes element within its Mesh Peering Open frames. The Supported Operating Classes element announces the operating classes that the mesh STA supports.

When dot11OperatingClassesImplemented is true, a mesh STA may switch from the operating channel to a channel in a different operating class.

11.9.8.5 HT-greenfield transmissions in operating classes that include a behavior limit of DFS_50_100_Behavior

The requirements described in this subclause apply only when an HT STA is operating in an operating class for which the behavior limits set listed in Annex E includes the value DFS_50_100_Behavior; i.e., the operating class is subject to DFS with 50–100 µs radar pulses.

A non-HT OBSS scan operation is a passive or active scan of the primary channel and of the secondary channel if the STA conducting the scan is in a 20/40 MHz BSS that the STA currently uses or intends to use. During a non-HT OBSS scan operation, the channel scan duration shall be a minimum of dot11OBSSScanPassiveTotalPerChannel TUs when scanning passively and a minimum of dot11OBSSScanActiveTotalPerChannel TUs when scanning actively.

Before an HT STA starts a BSS with the OBSS Non-HT STAs Present field of the HT Operation element equal to 0, the HT STA shall perform a non-HT OBSS scan in order to search for any existing non-HT OBSSs.

When an HT STA detects that there are one or more non-HT OBSSs, and if the HT STA starts a BSS on that channel, then the HT STA shall set to 1 the OBSS Non-HT STAs Present field of the HT Operation element it transmits; otherwise, the HT STA may set to 0 the OBSS Non-HT STAs Present field of the HT Operation element it transmits.

NOTE—Detection of a non-HT OBSS can be achieved by the reception of a Beacon or Probe Response frame that does not contain an HT Capabilities element or HT Operation element.

An HT AP shall not transmit a PPDU with the FORMAT parameter of the TXVECTOR set to HT_GF if the OBSS Non-HT STAs Present field of the HT Operation element is equal to 1 in the most recently transmitted Management frame that contained that element.

An HT non-AP STA shall not transmit a PPDU with the FORMAT parameter of the TXVECTOR set to HT_GF if the most recent frame received from its AP containing an HT Operation element has the OBSS Non-HT STAs Present field equal to 1.

NOTE—This requirement applies also to PPDUs transmitted on a direct link between two non-AP STAs.

When moving the BSS to a new channel or set of channels and before completing a non-HT OBSS scan of the new channel or set of channels, an HT AP shall set to 1 the OBSS Non-HT STAs Present field of the HT Operation element it transmits. After the HT AP completes one non-HT OBSS scan of the new channel or set of channels and if the HT AP has detected that there are zero non-HT OBSSs, then the HT AP may set to 0 the OBSS Non-HT STAs Present field of the HT Operation element it transmits.

11.9.8.6 Selecting and advertising a new channel in a DMG BSS

The decision to switch to a new operating channel in a DMG BSS shall be made only by an AP or PCP. An AP or PCP may make use of the information in received Supported Channel elements and the results of measurements undertaken by the AP or PCP and other STAs in the BSS to assist the selection of the new channel. The algorithm to choose a new channel is beyond the scope of this standard.

An AP or PCP shall inform associated STAs that the AP or PCP is changing to a new channel and shall maintain the association by advertising the switch using the Extended Channel Switch Announcement element in its transmitted DMG Beacon frames, Announce frames, and Information Response frames until the intended channel switch time. The channel switch should be scheduled so that all non-AP and non-PCP STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element before the switch. A STA may ignore the Channel Switch Mode field and either cease transmissions or attempt new transmissions in the operating channel until the channel change occurs.

A STA that receives an Extended Channel Switch Announcement element may choose not to perform the specified switch, but to take alternative action. For example, it may choose to move to a different BSS. A non-AP and non-PCP STA in an infrastructure BSS or PBSS shall not transmit the Extended Channel Switch Announcement element.

11.9.9 Channel Switch Announcement element operation

If a non-DMG STA in a BSS that is not an IBSS receives a Channel Switch Mode field that has the value 1, it shall not transmit any more frames on the channel until the scheduled channel switch occurs. An IBSS STA may treat a Channel Switch Mode field equal to 1 as advisory. A Channel Switch Mode equal to 0 does not impose any requirement on the STA that receives the Channel Switch Announcement frame.

11.9.10 Future Channel Guidance operation

This subclause defines a mechanism to create, communicate and act on the Future Channel Guidance element.

When `dot11FutureChannelGuidanceActivated` is true, a STA shall follow these procedures for future channel guidance operation.

A STA transmitting Beacon frames transmits the Future Channel Guidance element in (Re)Association Response frames and optionally in Beacon frames.

In some bands, the channel clearing time will be much less than one second for all STAs, and future channel guidance permits all STAs know what channels will be used if the current channels are cleared.

In some bands, Beacon frames are an enabling signal, and some STAs are not allowed to transmit in the band before receiving an enabling signal. When Beacon frame reception stops, some STAs are no longer enabled to transmit in the band. In these bands, when Beacon frame reception stops, it is an implicit message to switch from current channels to other channels according to prior future channel guidance.

Future channel guidance indicates future channels that the Beaconsing STA switches to while maintaining associations and mesh peering relationships (see 11.9.8.2, 11.9.8.3, 11.9.8.4.2, 11.9.8.6, 11.10.3.2, 11.10.3.3 and 11.10.3.4).

A STA receiving the Future Channel Guidance element shall retain the information until it receives a different Future Channel Guidance element from the same STA, it receives a Channel Switch Announcement element or a Channel Switch Announcement frame from the same STA, or it chooses alternative action. For example, it may choose to move to a different BSS.

11.10 Extended channel switching (ECS)

11.10.1 General

This subclause describes ECS procedures that change the BSS operating channel frequency and bandwidth. When the STA's dot11ExtendedChannelSwitchActivated value is true, the enabling STAs (see 11.12), APs, DFS owners, and mesh STAs may construct and transmit frames that contain Extended Channel Switch Announcement elements.

A STA shall use the ECS procedures defined in this subclause if dot11ExtendedChannelSwitchActivated is true. To indicate that it can perform ECS procedures, a STA shall set dot11ExtendedChannelSwitchActivated, dot11MultiDomainCapabilityActivated and dot11OperatingClassesRequired to true and shall set to 1 the value of the Extended Channel Switching field in the Extended Capabilities elements it transmits. When dot11ExtendedChannelSwitchActivated is false, the STA shall not use ECS procedures. When an AP is switching to a different channel and one or more of its associated STAs do not support extended channel switching capability, then both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames may be used.

If dot11ExtendedChannelSwitchActivated and dot11LCIDSERequired are true, frames containing Channel Switch Announcement elements shall not be transmitted.

An enabling STA may send frames containing Extended Channel Switch Announcement elements to dependent STAs (see 11.12.5). If dot11DSERequired is true, a STA shall perform ECS procedures to switch at the time indicated by the channel switch count, or the STA shall change its enablement state for the enabling STA to unenabled.

11.10.2 Advertising supported operating classes

When dot11ExtendedChannelSwitchActivated is true, the Current Operating Class field in the Supported Operating Classes element shall indicate the operating class in use for transmission and reception. The Operating Classes field shall list all operating classes with which the STA is capable of operating for the country that is specified in the Country element (9.4.2.9).

11.10.3 Selecting and advertising a new channel and/or operating class

11.10.3.1 General

An attempt may be made to move a BSS to a new operating channel and/or new operating class using extended channel switching. An objective during this process is to minimize disruption to the BSS. It is

possible, however, that an extended channel switch is not successful in moving all STAs to the new channel and/or operating class.

11.10.3.2 Selecting and advertising a new channel in an infrastructure BSS

When an AP with dot11DSERequired true receives frames containing Extended Channel Switch Announcement elements from the enabling STA, it shall advertise an extended channel switch with the same channel switch mode, new operating class, new channel number, and channel switch count as received in the Extended Channel Switch Announcement elements.

The decision to switch to a new operating channel and/or operating class in an infrastructure BSS is made by the AP when dot11DSERequired is false. An AP may make use of the information in the Supported Channels element, Supported Operating Classes element, and the results of measurements undertaken by the AP and other STAs in the BSS to assist the selection of the new channel and/or operating class. A method to make the decision and to select a new channel is defined in 11.9.8.2.

When an AP is switching to a different operating class and dot11ExtendedChannelSwitchActivated is true, then the AP shall use the Extended Channel Switch Announcement element and frame. In addition, the AP may also send Channel Switch Announcement elements and frames when the requirements signified by the new operating class are met by all associated STAs.

When an AP is switching to a new channel within the same operating class and dot11ExtendedChannelSwitchActivated is true, then the AP shall send the Extended Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames. If dot11ExtendedChannelSwitchActivated is false, the AP shall send the Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames.

When dot11ExtendedChannelSwitchActivated is true, an AP shall inform associated STAs that the AP is moving to a new channel and/or operating class and maintain the association by advertising the switch using Extended Channel Switch Announcement elements in any transmitted Beacon frames, Probe Response frames, and Extended Channel Switch Announcement frames until the intended channel switch time. The AP may request STAs in the BSS to stop transmissions until the channel switch takes place by setting the Extended Channel Switch Mode field to 1 in the Extended Channel Switch Announcement element. If possible, the channel switch should be scheduled so that all STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element before the switch. The AP may send the Extended Channel Switch Announcement frame without performing a backoff, after determining the WM is idle for one PIFS (see 10.3.2.3). When both the Extended Channel Switch Announcement and the Channel Switch Announcement elements are transmitted in Public Action frames, they shall be sent in separate frames.

If an Extended Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 40 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element may be present in the same frame if the STA sending the frame is extended spectrum management capable.

When a STA with dot11DSERequired equal to false receives an Extended Channel Switch Announcement element, it may choose not to perform the specified switch, but to take alternative action. For example, it might choose to move to a different BSS.

A non-AP STA in an infrastructure BSS shall not transmit the Extended Channel Switch Announcement element.

11.10.3.3 Selecting and advertising a new channel in an IBSS

When a DFS owner with dot11DSERequired true receives frames containing Extended Channel Switch Announcement elements from the enabling STA, it shall advertise an extended channel switch with the same channel switch mode, new operating class, new channel number, and channel switch count as received in the Extended Channel Switch Announcement elements.

The DFS owner that advertises a channel switch shall follow the rules defined in 11.9.8.3 with the following extensions:

- a) If a DFS owner is switching to a new channel or to the same channel in a different operating class and dot11ExtendedChannelSwitchActivated is true, then the DFS owner shall use the Extended Channel Switch Announcement element and frame. Alternatively, both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames may be used when Channel Switch Announcement elements and frames are permitted for operation in the band signified by the new operating class.
- b) If a DFS owner is switching to a new channel within the same operating class and dot11ExtendedChannelSwitchActivated is true, then the DFS owner shall send the Extended Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames. If dot11ExtendedChannelSwitchActivated is false, the DFS owner shall send the Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames.
- c) If both the Extended Channel Switch Announcement and the Channel Switch Announcement elements are transmitted in Public Action frames, they shall be sent in separate frames.

The DFS owner may transmit the Extended Channel Switch Announcement frame in an IBSS without performing a backoff, after determining that the WM is idle for one PIFS (see 10.3.2.3).

11.10.3.4 Selecting and advertising a new channel in an MBSS

A mesh STA may make use of the information in the Supported Channels element, Supported Operating Classes element, and the results of measurements undertaken by this mesh STA and other mesh STAs in the MBSS to assist the selection of the new channel and/or operating class.

If dot11ExtendedChannelSwitchActivated is true, the mesh STA that advertises a channel switch shall follow the rules defined in 11.9.8.4 with the following extensions:

- a) If a mesh STA is switching to a different operating class, then the mesh STA shall use the Extended Channel Switch Announcement element and frame. Alternatively, both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames may be used when Channel Switch Announcement elements and frames are permitted for operation in the band signified by the new operating class.
- b) If a mesh STA is switching to a new channel within the same operating class, then the mesh STA shall send the Channel Switch Announcement element and frame, or both the Extended Channel Switch Announcement and the Channel Switch Announcement elements and frames.
- c) If both the Extended Channel Switch Announcement and the Channel Switch Announcement elements are transmitted in Public Action frames, they shall be sent in separate frames.
- d) The Extended Channel Switch Announcement element shall be included in the Beacon and Probe Response frames until the intended channel switch time.

11.11 Radio measurement procedures

11.11.1 General

This subclause describes the radio measurements and the procedures for requesting and reporting radio measurements between STAs. When a STA implements support for one or more of the procedures described in this subclause, it shall set `dot11RadioMeasurementActivated` to true. When `dot11RadioMeasurementActivated` is true, `dot11MultiDomainCapabilityImplemented`, `dot11MultiDomainCapabilityActivated`, `dot11OperatingClassesImplemented`, and `dot11OperatingClassesRequired` shall be true.

NOTE—A key issue in radio measurement is network operation and management, considering each STA's service load, power state, and operating conditions. Timely measurement reports might be more important than percentage of wireless capacity or STA capacity used by radio measurements. The measurement requester might consider traffic load and application requirements, regulatory requirements, and specific measurement states from every STA in support of wireless network management. There are no typical scenarios that describe IEEE 802.11 operation in all bands. Off-channel measurements are desirable to gather timely information about the channel to which to switch BSS operation, and the noisier the operating environment, the more urgent the need for radio measurements off the serving channel. In any case, the measuring STA might refuse any measurement request.

11.11.2 Measurement on operating and nonoperating channels

Measurements on nonoperating channels might need the measuring STA to interrupt its data services on the operating channel, switch channels, and make measurements. Measurements on the operating channel might not require the STA to interrupt its data services.

All stations are responsible for maintaining data services and an association or membership with the BSS on the operating channel while performing measurements on nonoperating channels.

A STA shall determine the time between successive nonoperating channel measurements. This time may be a fixed length, or it may be determined by the STA using application-specific (or other) knowledge.

11.11.3 Measurement start time

A Radio Measurement Request frame may contain a single Measurement Request element or a sequence of Measurement Request elements. A STA that accepts the first or only measurement request within a Radio Measurement Request frame shall start the measurement as soon as practical after receiving the request. Subsequent measurement requests in the Radio Measurement Request frame that are accepted shall start as soon as practical after processing the previous request in the frame. Such measurement start times shall be subject to any specified randomization interval.

The radio measurement category permits a randomization interval to be specified for measurement start times. The intent of this is to avoid traffic storms that could arise with synchronized group addressed measurements. Prior to making each measurement in the requested sequence, the STA shall calculate a random delay distributed uniformly in the range 0 to the randomization interval specified in the measurement request. The STA shall not start the measurement until this delay has expired. Randomization interval is specified in units of TUs. A randomization interval field value of 0 in a measurement request indicates that no random delay is to be used.

NOTE—It is important that designers recognize the need for statistical independence among the pseudorandom number streams among STAs.

A number of repetitions may be specified in the Radio Measurement Request frame. In this case, the measurements in the frame are repeated as detailed further in 11.11.7. Each time a measurement is repeated, the STA shall recalculate the random delay as described above.

When a Measurement Start Time field is present in a measurement report, the measuring STA shall report the value of its TSF timer at the time the measurement started to an accuracy of ± 1 TU.

11.11.4 Measurement Duration

The values of Request Measurement Duration and Duration Mandatory in the received measurement request and the dot11RMMaxMeasurementDuration setting in the receiving STA determine if the receiving STA accepts the measurement request and for how long the measurement is performed. dot11RMMaxMeasurementDuration indicates a measurement duration using the following formula:

$$\text{Maximum Measurement Duration in TUs} = 2^{(\text{dot11RMMaxMeasurementDuration} - 4)} \times \text{BeaconInterval}$$

Table 11-8 describes how a STA responds to a measurement request depending on the values of dot11RMMaxMeasurementDuration, Measurement Duration, and Duration Mandatory.

Table 11-8—Measurement Duration

| dot11RMMaxMeasurementDuration | Measurement Duration in the Measurement Request | Duration Mandatory | Notes |
|-------------------------------|---|--------------------|---|
| 0 | Any value | 1 | The STA shall perform measurements for the requested measurement duration. |
| 0 | Any value | 0 | The STA may perform measurements for a duration shorter than the requested measurement duration |
| Nonzero | Any value | 0 | The STA shall perform measurements for a maximum duration that is equal to the minimum of the requested measurement duration and the dot11RMMaxMeasurementDuration. |
| Nonzero | Requested measurement duration > Maximum Measurement Duration in TUs | 1 | The STA shall reject the measurement request with the Measurement Report Mode set to “refused.” |
| Nonzero | Requested measurement duration \leq Maximum Measurement Duration in TUs | 1 | The STA shall perform the measurement for the requested duration. |

Measurement duration on nonoperating channels is defined by dot11RMNonOperatingChannelMaxMeasurementDuration. If this attribute is 0, the STA does not support RM measurements on nonoperating channels; on receipt of a Measurement Request frame requesting a measurement on nonoperating channels, the STA shall reject the measurement request by returning a Measurement Report element in which the Incapable bit in the Measurement Report Mode field is 1. The interpretation rules defined in Table 11-8 also apply for all nonzero values of dot11RMNonOperatingChannelMaxMeasurementDuration for measurements on nonoperating channels.

NOTE—Measurement duration on nonoperating channels is subject to further limitations due to maximum off-operating channel time.

If the Duration Mandatory bit is 1 in the Measurement Request mode field of a measurement request, the requested STA, if it accepts the request, shall perform the measurement over the Measurement Duration

specified in the request. If the STA is unable to commit to making the measurement over the requested duration, it shall refuse the request by sending a measurement report in which the refused bit in the Measurement Report Mode field is set to 1. The measurement duration in the measurement report is equal to the requested measurement duration.

If the Duration Mandatory bit is 0 in the Measurement Request mode field of a measurement request, the requested STA, if it accepts the request, shall attempt a measurement using the requested duration as a maximum measurement duration, and may report results with an actual measurement duration less than the requested duration. The duration over which the measurement was made will be included in the measurement duration field of the measurement report.

Each separate measurement within the Radio Measurement Request frame shall be performed over a continuous measurement duration time period. In Measurement Request frames the requested Measurement Duration value shall not be set to 0 except when the request frame is a Beacon request in which the Measurement Mode field value is Beacon Table, or is a STA Statistics request, or is a request for triggered autonomous measurements.

11.11.5 Station responsibility for conducting measurements

A radio measurement-capable STA shall decode and interpret each Radio Measurement Request frame that it receives and shall assess the contents against its capabilities and the impact on its own performance. A measurement request may be refused by the receiving STA by sending a Radio Measurement Report frame in which the refused bit in the Measurement Report Mode field is set to 1. The reasons for refusing a measurement request are outside the scope of this standard but may include reduced quality of service, unacceptable power consumption, measurement scheduling conflicts, or other significant factors.

In assessing the performance impact of each Measurement Request element, a STA may use application-specific knowledge or other knowledge to limit the time it spends away from the operating channel. In doing so, the STA may either:

- Reject any Measurement Request element in which the Duration Mandatory bit is 1 and that has a mandatory measurement duration exceeding the maximum allowed off-operating channel time, or
- Measure for a reduced duration if the Duration Mandatory bit is 0.

A STA shall cancel all in-process radio measurements and shall delete all pending, unprocessed radio measurement requests upon receipt of a Disassociation frame or upon (re)association with a BSSID different from its most recent association.

11.11.6 Requesting and reporting of measurements

A STA may perform radio measurements on one or more channels itself or a STA may request STAs in the same BSS to perform measurements on its behalf.

A STA advertises its radio measurement capability using the RM Enabled Capabilities element. If a STA advertises that it is capable of a measurement, it shall not reject a request for the corresponding measurement by sending a Radio Measurement Report frame in which the Incapable bit in the Measurement Report Mode field is set to 1, except as specified in 11.11.9.7. Measurement requests for radio measurements that the STA has advertised it is not capable of shall be rejected, and the corresponding report shall have the Incapable bit in the Measurement Report Mode field set to 1.

When requesting other STAs to measure one or more channels, a STA shall use a Radio Measurement Request frame containing one or more Measurement Request elements. The measurement request may be sent to an individual or group destination address. The permitted measurement requests are shown in Table 11-9.

Table 11-9—Allowed measurement requests

| Service set | Source of request | Destination of request | Receiver address of Measurement Request frame |
|--------------------|-------------------|------------------------|--|
| Infrastructure BSS | AP | Non-AP STA | Individual or group |
| | Non-AP STA | AP | Individual only |
| | Non-AP STA | Non-AP STA | Individual only for Direct Link within a BSS served by QoS AP, otherwise not allowed |
| IBSS | Non-AP STA | Non-AP STA | Individual or group |
| PBSS | PCP | STA | Individual or group |
| | STA | PCP | Individual only |
| | STA | STA | None |

The source and destination of a measurement request shall both be a member of the same infrastructure BSS, a member of the same PBSS, or a member of the same IBSS. Measurement requests with an individual Receiver Address shall be sent only to STAs that have indicated radio measurement capability.

The set of requested measurements received in the most recently received Radio Measurement Request frame of highest precedence is active. The precedence order for measurement requests shall be as follows (highest precedence first):

- Measurement requests received in individually addressed Radio Measurement Request frames
- Measurement requests received in Multicast-group addressed Radio Measurement Request frames
- Measurement requests received in Broadcast addressed Radio Measurement Request frames

The Measurement Request elements shall be processed in sequence by default, with certain Measurement Request elements processed in parallel according to the parallel bit field setting: see 9.4.2.21. A STA shall accept a measurement request with the parallel bit field enabled if `dot11RMParallelMeasurementsActivated` is true; otherwise, the STA shall reject the Measurement Request by returning a Measurement Report with the Incapable bit in the Measurement Report Mode field set to 1.

If `dot11RMParallelMeasurementsActivated` is true and if measurement resources are available, the STA processes each element by setting up and making the specified measurement. If measurement resources are not available to perform the requested parallel measurements, the STA shall return a Measurement Report with the Refused bit in the Measurement Report Mode field set to 1.

The Measurement Request elements within a Radio Measurement Request frame may specify multiple measurement types across multiple channels.

A STA may receive another Radio Measurement Request frame while the measurements requested in a previous Radio Measurement Request frame are pending or in progress. If this request is accepted, the set of measurement requests in the new frame supersedes any previous requests received in a Radio Measurement Request frame of the same or lower precedence. The measuring STA shall report the results of any completed measurements and terminate any pending or in-progress measurements. Results from a terminated in-progress measurement may be valid and reported if Duration Mandatory was not equal to 1 in the corresponding request. It is permissible for the superseding Radio Measurement Request frame to contain no new measurement requests. This has the effect of canceling all pending or in-progress measurements of the same or lower priority. If a station receives a Radio Measurement Request frame with

lower precedence than the currently active Radio Measurement Request frame, the station shall discard the measurement requests in the new Radio Measurement Request frame. Measurement Request elements that have the Enable bit equal to 1 shall be processed in all received Radio Measurement Request frames regardless of these precedence rules.

If a STA receives a Measurement Request frame with Measurement Type field equal to 0 (Basic request), this shall take priority over any pending or in-progress radio measurements.

A STA that issues a radio measurement request to another STA to perform a measurement on the operating channel may continue to transmit MPDUs and MMPDUs to that STA while the measurement is being processed.

A STA that issues a radio measurement request to another STA to perform a measurement on a nonoperating channel is not required to take any special action to suspend traffic to that STA. All stations shall maintain state information such that data services and association or membership with the BSS continue when returning from a nonoperating channel measurement.

A single Measurement Request element may generate a large quantity of measurement report data. The measurement report data may be reported using multiple measurement report elements in multiple measurement report frames. The result of each measurement requested in a Measurement Request element shall be reported in one or more Measurement Report elements of type corresponding to the request. Each Measurement Report element returned shall have the same Measurement Token as in the corresponding Measurement Request element, and the same Actual Measurement Start Time field, if present, as in the first returned Measurement Report element. The results of each measurement should be returned without undue delay to the requesting STA.

Measurement Report elements shall be returned to the requesting STA in one or more Radio Measurement Report frames. Each Radio Measurement Report frame shall contain the same Dialog Token field value as the corresponding Radio Measurement Request frame, and the same Actual Measurement Start Time field, if present, as in the first returned Measurement Report element.

When a STA is permanently unable to make a requested measurement, the STA shall respond to such a measurement request received within an individually addressed Radio Measurement Request frame with a measurement report indicating that it is incapable of completing the measurement request. A STA shall not respond to requests received in group addressed frames in this manner. Examples of when a response of incapable is appropriate are:

- The requested measurement type is not supported.
- The measuring STA cannot support requested parallel measurements due to the requests relating to different channels.

A STA that receives a response with an incapable indication shall not make the same request to the responding STA during the lifetime of the current association, or IBSS membership. This is logically the same as the responding STA using the Enable and Request bits in a measurement request to indicate that it does not accept measurement requests of a certain type. A STA that has indicated an incapable response to a requesting STA may discard further requests of the same type from that STA without responding.

A STA may refuse to make any requested measurement. A STA refusing a measurement request within an individually addressed Radio Measurement Request frame shall respond with a measurement report indicating that it is refusing the measurement request. A STA shall not respond to measurement requests received in Radio Measurement Request frames in this manner.

By default, a STA may send a radio measurement request of any defined measurement type. A STA that receives a Measurement Request element with the Enable bit equal to 1 and the Request bit equal to 0 shall

not issue a measurement request of the type specified in the request to the STA from which the element was received.

Since measurements on nonoperating channels interrupt normal operation on the operating channel, the requesting STA should consider each STA's service load, power state, and operating conditions. Since measurements on the operating channel execute concurrently with normal traffic processing, operating channel measurements can be requested more frequently and for longer durations.

11.11.7 Repeated Measurement Request frames

Radio Measurement Request frames contain a field specifying the number of repetitions for the Radio Measurement Request frame.

If the Radio Measurement Request frame includes a nonzero value for the Number of Repetitions and dot11RMRepeatedMeasurementsActivated is false, the STA shall reject the measurement request by returning a Measurement Report with the Incapable bit in the Measurement Report Mode field set to 1.

If the Radio Measurement Request frame includes a nonzero value for the Number of Repetitions and dot11RMRepeatedMeasurementsActivated is true, the STA shall iterate (repeat) the processing of all of the Measurement Request elements in the frame as specified by the value in the Number of Repetitions field. A value of 0 in the Number of Repetitions field indicates Measurement Request elements are executed once without repetition; a value of 1 in the Number of Repetitions field indicates Measurement Request elements are executed twice, one initial execution and one repetition; and so on. When completing the initial processing of the last Measurement Request element in the frame, the STA shall begin processing of the first Measurement Request element in the frame to repeat the frame until the number of iterations reaches the value in the Number of Repetitions field. Measurement Request elements with the Enable bit equal to 1 shall be processed once regardless of the value in the Number of Repetitions in the measurement request.

Each repeated measurement result shall include the same Measurement Token value as in the Measurement Token field of the corresponding Measurement request element and the same value of the Dialog Token field as in the Dialog Token field of the corresponding Radio Measurement Request frame.

Measurement results shall be reported for each repetition of a repeated measurement request subject to any conditional reporting requirement.

STAs responding with incapable or refused indications to measurement requests within a Radio Measurement Request frame with a nonzero value for Number of Repetitions shall respond only once.

11.11.8 Triggered autonomous reporting

Autonomous reporting is defined for spectrum management measurements supporting DFS; see 11.9.7. It allows a STA to report the results of measurements to a peer STA for which there was no explicit measurement request. In this case, the transmission of autonomous reports shall be entirely the decision of the STA at which such reporting has been enabled. An example of this use would be to report a change in conditions at the STA observed as a result of background measurement, e.g., the presence of a radar signal.

In radio measurement, triggered autonomous reporting shall be subject to trigger conditions set by the enabling STA that determine when measurement reports are issued. Triggered autonomous reporting provides a method for conditional reporting during continuous background measurements. An example of the use of triggered autonomous measurement is for reporting problem conditions in continuous, noninvasive statistical monitoring.

Triggered autonomous reporting is defined for the Transmit Stream/Category Measurement measurement type; see 11.11.9.8. When dot11MulticastDiagnosticsActivated is true, triggered autonomous reporting is

used for Multicast Diagnostics reports (11.11.19). When `dot11TriggerSTAStatisticsActivated` is true, triggered autonomous reporting is used for STA Statistics reports (11.11.9.5).

If `dot11RMTriggeredTransmitStreamCategoryMeasurementActivated` is true, a STA indicates that it wishes to accept triggered autonomous reports by sending a Measurement Request element with the Enable and Report bits set to 1; see 9.4.2.21. The type of measurement is indicated in the Measurement Type field. Trigger conditions that determine when measurement reports are to be generated shall be specified in the Measurement Request field. A Measurement Request element that is being used to control triggered autonomous reporting shall be sent within a Radio Measurement Request frame. Measurement Request elements being used to request measurements may also appear in the same Radio Measurement Request frame. The Radio Measurement Request frame may be sent to a group receiver address to enable triggered autonomous reports at more than one STA.

A STA shall not send autonomous reports for radio measurement types having triggered autonomous reporting enabled without a requested trigger condition having been met.

If a request to enable triggered autonomous reporting is sent to an individual address and the recipient STA does not support measurements of the type indicated or the recipient STA has `dot11RMTriggeredTransmitStreamCategoryMeasurementActivated` equal to false, a Measurement Report element shall be returned to the requesting STA with the Incapable bit set to 1. A STA may also refuse to enable triggered autonomous reporting. In this case a Measurement Report element shall be returned to the requesting STA with the refused bit set to 1. Such responses shall not be issued if the request to enable triggered autonomous reporting was sent to a group address.

A STA receiving a request to enable triggered autonomous reporting from another STA may send reports of the appropriate type, addressed to the individual address of the STA that sent the enable request. Autonomous reports shall be sent only to the individual addresses of STAs from which a valid enable request has been received and shall be issued only when a requested trigger condition has been met. The Measurement Token in each Measurement Report element and the value of the Dialog Token field in the Measurement Report frame shall both be set to 0 in a triggered autonomous report.

A STA may update the trigger conditions set for triggered autonomous reports by issuing a new Measurement Request element with the Enable and Report bits both set to 1, the Measurement Type field set to the appropriate type and the Measurement Request field indicating the new trigger conditions. A STA disables all triggered autonomous measurement reports by sending a Measurement Request element with the Enable bit set to 1 and the Report bit set to 0; see 9.4.2.21.

A STA in an infrastructure BSS or PBSS shall cease all triggered autonomous reporting if it disassociates, or reassociates to a different BSS (reassociation to the same BSS shall not affect triggered reporting). An IBSS STA shall cease all triggered autonomous reporting if it leaves the BSS.

Triggered autonomous reporting and requested measurements are independent: a STA may request measurements from another STA even if it has enabled triggered autonomous reporting from that STA. All Measurement Request elements received in Radio Measurement Request frames that have the Enable bit equal to 1 shall be processed without regard for the measurement precedence rules for requested measurements in 11.11.6.

A number of triggered measurements may run concurrently at a non-AP STA. The number of simultaneous triggered measurements supported is outside the scope of the standard. Each triggered measurement is logically separate; reporting conditions such as Trigger Timeout periods apply only to the measurement for which they are established.

11.11.9 Specific measurement usage

11.11.9.1 Beacon report

If a STA accepts a Beacon request it shall respond with a Radio Measurement Report frame containing Beacon reports for all observed BSSs matching the BSSID and SSID in the Beacon request, at the level of detail requested in the Reporting Detail. If the Reporting Detail is 1 and the optional Request subelement is included in the Beacon request, the corresponding Beacon report shall include the list of elements listed in the Request subelement. The RCPI in the Beacon report indicates the power level of the received Beacon, Measurement Pilot, or Probe Response frame. For repeated measurements (when the Measurement Request frame contains a nonzero value for the Number of Repetitions field), the transmission of the Beacon report may be conditional on the measured RCPI or RSNI value. If the Measurement Request frame contains a 0 value for the Number of Repetitions field, the Beacon Reporting subelement shall not be included in the Beacon request. If the Measurement Request frame contains a nonzero value for the Number of Repetitions field, and if both dot11RMBeaconMeasurementReportingConditionsActivated and dot11RMRepeatedMeasurementsActivated are true, and if a Beacon Reporting subelement is included in a Beacon request, the STA shall respond with a Beacon report if the indicated Beacon reporting condition is true. Otherwise, the STA shall not respond with a Beacon report. Table 9-89 lists the reporting conditions that are based on the measured RCPI or RSNI levels.

If the requested Beacon report includes the Supported Operating Classes element, then the channel number, operating class, and/or reported frame information for that measurement may be included in the beacon report; otherwise these fields shall be set to 255 in the beacon report. The STA shall use the Reporting Detail specified in the measurement request to determine the data to be included in the measurement report. If the STA has no beacon information available then the STA may either refuse the request or send an empty Beacon report.

If dot11RMBeaconPassiveMeasurementActivated is true and the Measurement Mode in the measurement request is Passive, the measuring STA shall perform the following procedure (or an equivalent procedure) on the requested channel:

- Set a measurement duration timer.
- At the end of the measurement duration, process all received Beacons or Probe Response frames with the requested SSID and BSSID to compile the measurement report. The STA shall use the Reporting Detail specified in the measurement request to determine the data to be included in the measurement report. If no Beacon or Probe Response frames with the requested SSID and BSSID were received in the measurement duration, then process all Measurement Pilot frames with the requested BSSID to compile the measurement report. Otherwise, compile an empty Beacon report.

If dot11RMBeaconPassiveMeasurementActivated is false and the Measurement Mode in the measurement request is Passive, the measuring STA shall reject the measurement request by returning a Beacon report with the Incapable bit in the Measurement Report Mode field set to 1.

If dot11RMBeaconActiveMeasurementActivated is true and the Measurement Mode in the measurement request is Active, the measuring STA shall perform the following procedure (or an equivalent procedure) on the requested channel:

- If the channel is not the operating channel, wait for dot11RMMeasurementNavSync, or until a PHY-RXSTART.indication primitive has been received.
- Using the basic access protocol in 10.3.4.2, send a Probe Request frame to the broadcast destination address (DA). The BSSID field in the Probe Request frame shall be set to the BSSID field in the measurement request. The SSID element in the Probe Request frame shall be set to the SSID element in the measurement request.
- Set a measurement duration timer.

- At the end of the measurement duration, process all received Probe Response and Beacon frames with the requested SSID and BSSID to compile the measurement report. The STA shall use the Reporting Detail specified in the measurement request to determine the data to be included in the measurement report. If no Beacons or Probe Response frames were received in the measurement duration and Measurement Pilot frames with the requested BSSID were received in the measurement duration, then process all these Measurement Pilot frames to compile the measurement report. Otherwise, compile an empty Beacon report.

If `dot11RMBeaconActiveMeasurementActivated` is false and the Measurement Mode in the measurement request is Active, the measuring STA shall reject the measurement request by returning a Beacon report with the Incapable bit set in the Measurement Report Mode field.

When more than one Beacon or Probe Response from a BSS is received in the measurement duration, the contents of the Beacon report shall be based on the latest received. If only Measurement Pilot frames were received in the measurement duration, the contents of the Beacon report shall be based on the latest Measurement Pilot frame received.

If the BSSID field in the Measurement Request contains a wildcard BSSID, all observed BSSs with the requested SSID shall be reported in a separate Beacon report for each BSSID. If the SSID subelement is not included in the Beacon request, all observed BSSs shall be reported in a separate Beacon report for each BSSID. In active mode, Probe Response frames shall be evaluated regardless of whether the Probe Response frame was triggered by the measuring STA's Probe Request.

On accepting an active or passive mode Beacon request, a STA shall conduct measurements as follows:

- If the Channel Number is 0 and the Operating Class identifies the location of the primary channel, then a STA shall conduct iterative measurements on all supported channels in the specified Operating Class where the measurement is permitted on the channel and the channel is valid for the current regulatory domain.
- If the Channel Number is 0 and if the Operating Class encompasses a primary channel but does not identify the location of the primary channel, then a STA shall conduct iterative measurements on all primary channel positions within all requested and supported channels where the measurement is permitted on the channel and the channel is valid for the current regulatory domain.
- If the Channel Number is 255, the Operating Class identifies the location of the primary channel, and the Beacon request includes AP Channel Report subelements, a STA shall conduct iterative measurements on all supported channels listed in the AP Channel Report subelements that are valid for the current regulatory domain. If there is no AP Channel Report subelement included in the Beacon request, a STA shall conduct iterative measurements on all supported channels listed in the latest AP Channel Report received from the serving AP that are valid for the current regulatory domain. If there are no AP Channel Report subelements included in the Beacon request, and no AP Channel Report included in last received AP Beacon frame, the STA shall reject the Beacon request.
- If the Channel Number is 255, the Operating Class encompasses a primary channel but does not identify the location of the primary channel, and the Beacon request includes AP Channel Report subelements, then a STA shall conduct iterative measurements on all primary channel positions within all requested (in the AP Channel Report) and supported channels that are valid for the current regulatory domain. If there are no AP Channel Report subelements included in the Beacon request, the STA shall reject the Beacon request.
- If the Channel Number is a value other than 0 or 255, a STA shall conduct iterative measurements on the requested channel, where the measurement is permitted on the channel and the channel is valid for the current regulatory domain.

Except when the Measurement Mode field is equal to Beacon Table, measurements shall be made using the specified Measurement Duration with the time between each consecutive measurement as defined in

11.11.2. Iterative measurements shall cease when all channels have been measured. While the STA is processing a Beacon request for iterative channel measurements, the STA shall not begin processing the next measurement request in the Measurement Request frame.

If `dot11RMBaconTableMeasurementActivated` is true and the Measurement Mode in the measurement request is Beacon Table, the measuring STA shall return a Beacon report containing the current contents of any stored beacon information for any supported channel with the requested SSID and BSSID without performing additional measurements. The receiving STA shall ignore the channel and measurement duration specified in the Beacon request when the Measurement Mode field contains Beacon Table. The beacon information accumulated may be the result of any operation that caused the STA to acquire these results. If the stored beacon information is based on a measurement made by the reporting STA, and if the actual measurement start time, measurement duration, and Parent TSF are available for this measurement, then the beacon report shall include the actual measurement start time, measurement duration, and Parent TSF; otherwise the actual measurement start time, measurement duration, and Parent TSF shall be set to 0. The RCPI and RSNI for that stored beacon measurement may be included in the beacon report; otherwise the beacon report shall indicate that RCPI and RSNI measurements are not available.

If `dot11RMBaconTableMeasurementActivated` is false and the Measurement Mode in the measurement request is Beacon Table, the measuring STA shall reject the measurement request by returning a Beacon report with the Incapable bit set in the Measurement Report Mode field.

For repeated measurements, the Beacon request may include a Beacon Reporting subelement that determines when the measuring STA is to send a Beacon report for a measured Beacon, Measurement Pilot, or Probe Response frame with the requested SSID and BSSID. When the requested Reporting Condition value is nonzero, and `dot11RMBaconMeasurementReportingConditionsActivated` is true, the STA shall create and transmit a Beacon report for that measured frame if the condition indicated in Table 9-89 is true. Otherwise, the STA shall not transmit a Beacon report for that measured frame. If multiple Beacons, Measurement Pilots, or Probe Response frames with the requested specific BSSID are received during the measurement duration, the reporting condition shall be applied only to the latest received Beacon, Measurement Pilot, or Probe Response frame. If multiple Beacons, Measurement Pilots, or Probe Response frames are received during the measurement duration when a wildcard BSSID is requested, the STA shall generate one Beacon report for each BSSID occurring in frames that satisfy the reporting condition; the Beacon report shall be based on the latest received Beacon, Measurement Pilot, or Probe Response frame for that specific BSSID. For reporting conditions 5–10, the serving AP’s reference RCPI level and the serving AP’s reference RSNI level referred to in Table 9-89 are average values of the RCPI or RSNI of the 16 most recent Beacon frames received from the measuring STA’s serving AP. The serving AP’s reference RCPI level and the serving AP’s reference RSNI level are so averaged to provide a more accurate and stable indication of the signal level from the serving AP. For reporting conditions 5–10, the STA shall use the serving AP’s reference RCPI level or reference RSNI level (with offset, if any) to test the measured RCPI or RSNI to determine whether to create and send a Beacon report for this measured Beacon, Measurement Pilot, or Probe Response frame.

The STA shall return a Beacon report with the Incapable bit set in the Measurement Report Mode field in the following cases:

- Reporting Condition in the Beacon request is nonzero and `dot11ReportingConditionsActivated` is false,
- Reporting Condition in the Beacon request is nonzero and the Number of Repetitions in the Measurement Request frame is 0.

NOTE—Reporting conditions described here for repeated Beacon request measurements are distinct from the conditions defined elsewhere for triggered measurements.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Beacon request or Beacon report. A STA shall not include a Wide Bandwidth

Channel Switch subelement in a Beacon request or Beacon report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Beacon request or Beacon report, then the Operating Class shall indicate a 40 MHz channel spacing.

If N (where $N \geq 1$) AP Channel Report subelements containing an Operating Class with an 80+ behavior limit (the 80+ behavior limit is defined in Table D-2, the operating classes that might use this limit are defined in E.1) are included contiguously in a Beacon request, then the N subelements shall be followed by one AP Channel Report subelement containing an Operating Class without an 80+ behavior limit (as defined in Annex E). All $N+1$ Channel List fields in each of these subelements shall contain the same number L of channel numbers. This sequence of $N+1$ AP Channel Report subelements indicates a list of L noncontiguous channels comprising $N+1$ frequency segments, where the l th channel number in the n th Channel List field identifies the channel center frequency of the n th frequency segment.

NOTE—To identify the BSS bandwidth, the Beacon request might include a Request subelement listing the element IDs of the HT Operation and VHT Operation elements. The Beacon report would then include the requested elements, which contain fields defining the BSS bandwidth.

11.11.9.2 Frame report

If dot11RMFrameMeasurementActivated is true, and a station accepts a Frame request, it shall respond with a Radio Measurement Report frame containing one or more Measurement Report elements with the Measurement Type field set to Frame. (See 9.4.2.22.8.)

If the MAC Address field included in the Frame request was not set to the broadcast address, a Frame Report Entry field where Transmitter Address (TA) matching the MAC address field value shall be included in the Frame report if at least one Data or Management frame was received with this Transmitter Address during the measurement duration. If the MAC address field included in the Frame request was set to the broadcast address, the measuring station shall report all Data or Management frames received during the measurement duration in one or more Frame reports.

If the Frame Request Type of the corresponding Frame request equals 1, then each Frame report contains one Frame Count subelement that contains in turn one or more Frame Report Entries. The measuring station shall count the number of individually addressed Data and Management frames received from one transmit address during the measurement duration and shall summarize this traffic in a frame report entry.

Each Frame Report Entry field contains the Transmit Address, BSSID, PHY Type, Average RCPI, Last RSNI, Last RCPI, Antenna ID, and Frame Count for the frames counted in this Frame Report Entry field.

The reported Average RCPI shall be an average of the RCPI values of frames received and counted in the Frame Report Entry field. If there are up to 32 frames, then the Average RCPI indicates the mean of the RCPI of each of the frames. If there are more than 32 frames, then the Average RCPI indicates an exponentially weighted average, initialized by the mean RCPI of the first 32 frames and exponentially updated by new RCPI values. The averaging is calculated as follows.

If the number of frames received is less than or equal to 32:

$$\text{Average RCPI} = \text{Sum of RCPI values} / \text{Number of frames}$$

For 33 received frames and above:

$$\text{Average RCPI} = (\text{Last Average RCPI} \times 31 / 32) + (\text{Current frame RCPI} / 32)$$

The Last RCPI shall be the RCPI value of the most recently received frame counted in the Frame Report Entry field. The Antenna ID field contains the identifying number for the antenna(s) used to receive the most recently received frame included in this Frame Report Entry field as defined in 9.4.2.40. If different

antennas are used to receive the frame preamble and the frame body, this Antenna ID shall contain the identifying number for the antenna(s) used to receive the frame body.

If `dot11RMFrameMeasurementActivated` is false, a station shall reject the received Frame request by returning a Frame report in which the Incapable bit in the Measurement Report Mode field is 1.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Frame request or Frame report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Frame request or Frame report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Frame request or Frame report, then the Operating Class shall include a 40 MHz channel spacing.

11.11.9.3 Channel load report

If `dot11RMChannelLoadMeasurementActivated` is true and a station accepts a Channel Load request, it shall respond with a Radio Measurement Report frame containing one Measurement (Channel Load) Report element. The Channel Load field is defined as the percentage of time, linearly scaled with 255 representing 100%, the STA sensed the medium was busy, as indicated by either the virtual carrier sense mechanism or the physical carrier sense mechanism over the requested channel width (together referred to as the *CS mechanism*). This percentage is computed using the following formula:

$$\text{Channel Load} = \left\lfloor \frac{\text{channel busy time}}{\text{MeasurementDuration} \times 1024} \times 255 \right\rfloor$$

where channel busy time is defined to be the number of microseconds during which the CS mechanism, as defined in 10.3.2.1, has indicated a channel busy indication for the requested channel width.

If `dot11RMChannelLoadMeasurementActivated` is false, a station shall reject the received Channel Load request by returning a Channel Load report with the Incapable bit in the Measurement Report Mode field set to 1.

If `dot11RMChannelLoadMeasurementActivated` is true and if a Channel Load Reporting subelement is included in a Channel Load request, the STA shall respond with a Channel Load report if the indicated channel load reporting condition is true. Otherwise, the STA shall not respond with a Channel Load report.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Channel Load request or Channel Load report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Channel Load request or Channel Load report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Channel Load request or a Channel Load report, then the Operating Class shall indicate a 40 MHz channel spacing.

11.11.9.4 Noise Histogram report

If `dot11RMNoiseHistogramMeasurementActivated` is true and a station accepts a Noise Histogram request, it shall respond with a Radio Measurement Report frame containing one Measurement (Noise Histogram) Report element. The Noise Histogram report shall contain the IPI densities observed in the channel for the IPI levels defined in Table 9-110.

To compute the IPI densities, a STA shall measure the amount of time, in microseconds, during which the IPI is in each IPI range specified in Table 9-110. These IPI measurements shall be taken over the entire associated channel bandwidth, and during the requested measurement duration except for those time intervals during which the NAV is not equal to 0 (when virtual CS mechanism indicates channel busy), or

during which frame transmission or reception is occurring. The IPI densities are then computed for each of the nine possible IPI values using:

$$\text{IPI Density} = \text{Integer} \left[\frac{255 \times D_{IPI}}{(1024 \times D_M) - T_{NAV} - T_{TX} - T_{RX}} \right]$$

where

D_{IPI} is the duration receiving at the specified IPI value (μs)

D_M is the measurement duration (TU)

T_{NAV} is the total time that NAV is nonzero during the Measurement Duration (μs)

T_{TX} is the frame transmission time during the Measurement Duration (μs)

T_{RX} is the frame reception time during the Measurement Duration (μs)

The sum of the IPI densities is approximately 255. If either the NAV is nonzero, or if there is frame transmission, or if there is frame reception throughout the entire measurement duration period, no reportable IPI values are measured, and all IPI Densities shall be set to 0 in the Measurement Report element.

A STA shall include in the Noise Histogram report an average noise power indicator (ANPI) value representing the average noise plus interference power on the measured channel at the antenna connector during the measurement duration. The STA may use Noise Histogram IPI density values to calculate ANPI. The IPI densities in the Noise Histogram report may be used to calculate an average noise power for the channel during the measurement duration. This calculated average IPI power value may be reported as the value for ANPI. Any equivalent method to measure ANPI may also be used. ANPI power is defined in dBm using the same accuracy as defined for RCPI.

ANPI may be calculated over any period and for any received frame. ANPI may be calculated in any period and at any time by filtering all PHY IPI values in a MAC filter to exclude IPI values received when NAV is nonzero. These filtered IPI values represent idle channel noise and may be stored in a first-in-first-out (FIFO) buffer to facilitate ANPI calculation over a fixed number of IPI samples. ANPI may be so calculated upon receipt of any frame and may be used with RCPI to calculate RSNI for any received frame. Any equivalent method to measure ANPI may also be used to calculate RSNI for any received frame.

If `dot11RMNoiseHistogramMeasurementActivated` is false, a station shall reject the received Noise Histogram request by returning a Noise Histogram report with the Incapable bit in the Measurement Report Mode field set to 1.

If `dot11RMNoiseHistogramMeasurementActivated` is true and if a Noise Histogram Reporting subelement is included in a Noise Histogram request, the STA shall respond with a Noise Histogram report if the indicated noise histogram reporting condition is true. Otherwise the STA shall not respond with a Noise Histogram report.

A STA that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Noise Histogram request or Noise Histogram report. A STA shall not include a Wide Bandwidth Channel Switch subelement in a Noise Histogram request or Noise Histogram report sent to a STA that is not extended spectrum management capable. If the Wide Bandwidth Channel Switch subelement is included in a Noise Histogram request or a Noise Histogram report, then the Operating Class shall indicate a 40 MHz channel spacing.

11.11.9.5 STA Statistics report

If `dot11RMSStatisticsMeasurementActivated` is true and a station accepts a STA Statistics request, it shall respond with a Radio Measurement Report frame including one STA Statistics report. If the Requested

Measurement Duration value is 0, the STA shall report the current values for the requested Statistics Group Data. If the Requested Measurement Duration value is greater than 0, the STA Statistics report reports the change in the requested Statistics Group Data measured within that nonzero Measurement Duration. The reported change in data value shall be the value of the data at the end of the actual Measurement Duration minus the value of the data at the beginning of the actual Measurement Duration. If a STA accepts a STA Statistics request measurement with nonzero, positive Measurement Duration, the STA shall perform the measurement over the requested Measurement Duration without regard to the Duration Mandatory bit in the Measurement Request Mode field. If a STA cannot measure over the requested Measurement Duration, the STA shall refuse the Statistics request measurement.

If `dot11RMStatisticsMeasurementActivated` is false, a station shall reject the received STA Statistics request by returning a Statistics Measurement Report with the Incapable bit in the Measurement Report Mode field set to 1.

A STA may request that a STA Statistics report be sent when statistics of interest reach a threshold as defined in the Measurement Request element of the STA Statistics request frame (see 9.4.2.21.9). This is termed a triggered STA Statistics measurement. Implementation of Triggered STA Statistics Reporting is optional for a WNM STA. A STA that implements Triggered STA Statistics Reporting has `dot11TriggerSTAStatisticsImplemented` equal to true. When `dot11TriggerSTAStatisticsImplemented` is true, `dot11WirelessManagementImplemented` shall be true.

A triggered STA Statistic measurement shall be requested by setting the Enable and Report bits to 1 within a Measurement Request element with the Measurement Type field set to STA Statistics. The Measurement Request field shall contain a STA Statistics request with the trigger conditions specified in the Triggered Reporting subelement, as defined in 9.4.2.21.9. One or more trigger conditions shall be set with specified thresholds. See 11.11.8. To prevent generation of too many triggered reports, the value of the Trigger Timeout field shall be set to a value greater or equal to `dot11MinTriggerTimeout`. If the value of the Trigger Timeout field is less than `dot11MinTriggerTimeout`, the STA shall reject the measurement request by returning a report where the Measurement Report Mode field is “Incapable.”

A STA accepting a triggered STA Statistics measurement shall measure the requested statistics. If a trigger condition occurs, the measuring STA shall send a STA Statistics measurement report to the requesting STA. The measuring STA shall not send further triggered STA Statistics reports for that trigger condition to the requesting STA until the Trigger Timeout period specified in the request frame has expired. The STA Statistics measurement report is defined in 9.4.2.21.9. If the number of MPDUs or MSDUs indicated in the Measurement Count field are transmitted or received without any of the counted statistics meeting the corresponding trigger threshold then the measuring STA shall restart measuring for another measurement count window.

If a STA receives a STA Statistics request from the same STA for which a triggered STA Statistics measurement is in progress, the in-progress triggered measurement shall be terminated.

STA Statistics reported in a triggered STA Statistics report shall be the values accumulated over the number of transmitted or received MSDUs or MPDUs before the trigger condition is met. Measurement duration shall not be specified when requesting a triggered STA statistics measurement and the Measurement Duration field in the corresponding Measurement Request shall be set to 0.

All triggered STA Statistics measurements shall be terminated at a measuring STA by receiving a STA Statistics request with the Enable bit equal to 1 and the Report bit equal to 0. A STA requesting a triggered STA Statistics measurement may update the trigger conditions by sending a STA Statistics request specifying the new trigger conditions.

Once accepted by a measuring STA, a triggered STA Statistics measurement continues to be active until the measurement request is superseded by a STA Statistics request from the requesting STA or the measuring STA disassociates or reassociates.

11.11.9.6 LCI report (Location configuration information report)

If dot11RMLCIMeasurementActivated is true, a STA that receives an LCI request for location information that is not available shall respond with a Radio Measurement Report frame including a Radio Measurement Report element with the Refused bit set to 1. If dot11RMLCIMeasurementActivated is true and a STA accepts an LCI request that does not include an azimuth request, it shall respond with a Radio Measurement Report frame including one LCI subelement (LCI report). If both dot11RMLCIMeasurementActivated and dot11RMLCIAzimuthActivated are true, and the STA accepts an LCI request that includes an azimuth request, it shall respond with a Radio Measurement Report frame that includes one LCI subelement (LCI report) and the requested Azimuth Report, if available. If dot11RMLCIAzimuthActivated is false, a STA that receives an LCI request that includes an azimuth request shall respond with a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable bit set to 1.

The Datum value shall be 1 (World Geodetic System 1984), unless another datum is required for operation in the regulatory domain.

If the Altitude Type is 2 (Floors of Altitude), the value reported shall be as required for operation in the regulatory domain.

An LCI request shall indicate a location request for the requesting STA, the reporting STA, or a third STA with the MAC address specified in the Target MAC Address subelement, by setting the LCI request Location Subject field to indicate a Local, a Remote, or a third-party request, respectively. Local LCI request is used by the requesting STA to obtain its own location by asking “Where am I?” Remote LCI request is used by requesting STA to obtain location of reporting STA by asking “Where are you?” Third-party location request is used by requesting STA to obtain location of a STA with the MAC address specified in the Target MAC Address subelement.

The Latitude, Longitude, and Altitude fields of the LCI report shall be reported at their best known resolutions unless otherwise configured.

If the STA receiving an LCI request has no location information about the requested LCI subject’s physical location, the STA shall send a LCI subelement indicating an unknown LCI (see 9.4.2.22.10). If the STA receiving an LCI request has no location information about the requested Azimuth, the STA shall omit the Azimuth Report subelement. If the STA receiving an LCI request that contains a Maximum Age subelement has already determined the requested LCI within the indicated maximum age, the STA may respond with its already determined LCI; otherwise, the STA shall update its LCI before the STA responds with its LCI. The method by which the physical location and azimuth information in the LCI report is generated is outside the scope of this standard.

A STA that receives an LCI report that contains a Usage Rules/Policy subelement shall process the LCI information in compliance with the retransmission and retention permissions in the Usage-rules subelement.

NOTE—A STA that requested an LCI including an Azimuth Request, and received an LCI report in which the Incapable bit is 1 might alternatively request the LCI with no Azimuth requested.

If dot11RM3rdPartyMeasurementActivated is false, a STA that receives an LCI request that includes an LCI request with the Location Subject field equal to 2 shall respond with a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable bit set to 1.

It is optional for a STA to support an LCI request and an LCI report with the Location Subject field equal to 2. If dot11RM3rdPartyMeasurementActivated is true and a STA supports LCI request and LCI report, the following procedure shall be followed:

- When a non-AP STA requests the geospatial location of a STA with the MAC address specified in the Target MAC address field, it shall also include its own MAC address in the Originator Requesting STA MAC address field. When an AP receives an LCI request with the Location Subject field value equal to 2, the AP shall generate an LCI request to the STA with the MAC address specified in the Target MAC address field. If the AP does not have an association with the STA with the MAC address specified in the Target MAC address field, the AP shall reject the received LCI request by returning an LCI report where the Incapable bit is set in the MeasurementReport Mode field. The AP shall copy the Originator Requesting STA MAC address and Target MAC address fields into the request from the received LCI request.
- When a STA receives an LCI request with the Location Subject field value equal to 2, the STA may generate an LCI report if the MAC address in the Target MAC address field is its own MAC address; it shall not generate an LCI report otherwise. When an LCI report is generated, the reporting STA shall include its MAC address into the Target MAC address field and the MAC address present in the Originator Requesting STA MAC address field of the corresponding LCI request into the Originator Requesting STA MAC address field. When an AP receives an LCI report with an Originator Requesting STA MAC address field present, the AP shall generate an LCI report to the associated STA with the MAC address specified in the Originator Requesting MAC address field. The AP shall copy the Originator Requesting STA MAC address and Target MAC address fields into the LCI report being transmitted to the originating requesting STA.

If dot11RMLCIMeasurementActivated is false, a station shall reject the received LCI request by returning an LCI report with the Incapable bit in the Measurement Report Mode field set to 1.

If dot11RMLCIMeasurementActivated is true and a STA has its own location configured in LCI format excluding an unknown LCI as defined in 9.4.2.21.10, the STA shall set dot11RMLCIConfigured to true.

NOTE—It is recommended that User Applications not send location information to other stations without the express permission of the user. User agents acquire permission through a user interface, unless they have prearranged trust relationships with users. Those permissions that are acquired through the user interface and that are preserved beyond the current browsing session (i.e., beyond the time when the BSS connection is terminated) are revocable and receiving stations should respect revoked permissions. Some user applications might have prearranged trust relationships that do not require such user interfaces. For example, while a social networking application might present a user interface when a friend performs a location request, a VOIP telephone might not present any user interface when using location information to perform an E911 function.

11.11.9.7 Measurement Pause

A measurement pause is used within a Measurement Request frame to provide a time delay between the processing of two other Measurement Request elements within the sequence of Measurement Request elements in that frame.

If a STA accepts a Measurement Pause request it shall delay processing of the next measurement request in the Measurement Request frame. If the Measurement Pause request is the last Measurement Request element in a repeated Measurement Request frame, the STA shall delay processing the first Measurement Request element in the Measurement Request frame for the next repeat. In each case the delay shall be no less than the Pause Time value specified in the Measurement Pause request.

NOTE—Measurement pause is always supported by a STA implementing radio measurements.

A measurement pause shall not be sent as the only Measurement Request element in a Measurement Request frame. A measurement pause shall not be included as the last Measurement Request element in a Measurement Request frame that has the Number of Repetitions field equal to 0.

A measurement pause cannot be processed in parallel to other measurements. If the Parallel bit is 1 in the Measurement Request element immediately prior to a measurement pause, an incapable response shall be returned even if dot11RMPARallelMeasurementsActivated is true.

There is no measurement report associated with a Measurement Pause request.

11.11.9.8 Transmit Stream/Category Measurement report

The Transmit Stream/Category Measurement applies to TIDs for Traffic Streams associated with TSPECs and also to TIDs for Traffic Categories for QoS traffic without TSPECs.

If dot11RMTransmitStreamCategoryMeasurementActivated is true and has no resource constraint that prevents it from being able to make the requested measurement, a QoS STA receiving a Transmit Stream/Category Measurement request shall respond with a Radio Measurement Report frame containing one Measurement (Transmit Stream/Category Measurement) Report element. If the traffic stream (TS) that is corresponding to the Traffic Identifier is deleted, either by a DELTS frame or by disassociation, the STA shall cease sending Radio Measurement Reports.

If dot11RMTransmitStreamCategoryMeasurementActivated is false, a STA shall reject the received Transmit Stream/Category Measurement request by returning a Transmit Stream/Category Measurement report with the Incapable bit in the Measurement Report Mode field set to 1.

The transmit stream/category measurement shall be made on traffic that is transmitted from the measuring QoS STA to the peer QoS STA and TID indicated in the request. The Peer STA Address may be the MAC address of the QoS STA from which the Measurement Request was sent, the MAC address of another QoS STA within the BSS, or the broadcast address. This enables a QoS AP to query Transmit Stream/Category Measurement metrics for DLS links. A broadcast address shall be used only with a TID corresponding to a TC. In the case of a broadcast address, measurement shall be made on all traffic for the specified TC. Depending on policy, a QoS AP may disallow transmit stream/category measurement requests for traffic to other QoS STAs in the BSS. In this case the QoS AP shall respond with a matching Measurement Report frame with the Incapable subfield of the Measurement Report Mode field set to 1.

If, during the course of a Transmit Stream/Category Measurement, any counter that is included in the Transmit Stream/Category Measurement report increments to a value of $2^{32}-1$, the Transmit Stream/Category Measurement shall terminate, and the Transmit Stream/Category Measurement report shall indicate the shortened, actual measurement duration.

If the measurement request included multiple transmit stream/category measurement requests for multiple TIDs, the corresponding measurement report shall include a transmit stream/category measurement report for each unique TID in the request that has been admitted. If the measurement request is for a TID that has not been admitted yet, a report is generated only after the TID becomes admitted.

The requesting and reporting STAs are QoS STAs. A non-QoS STA receiving a Transmit Stream/Category Measurement request shall reject the request by returning an indication of incapable.

A QoS STA may request that a measuring QoS STA send a transmit stream/category measurement report when the number of TID-specified MSDUs are discarded or delayed reaches a specified threshold. This is termed a triggered transmit stream/category measurement and shall be requested by setting the Enable and Report bits to 1 within a Measurement Request element containing the Transmit Stream/Category Measurement Type. The Measurement Request field shall contain a Transmit Stream/Category Measurement request with the trigger conditions specified in the Triggered Reporting subelement. One or more trigger conditions may be set with specified thresholds. See 9.4.2.21.11.

Depending on policy, a QoS AP might not permit the establishment of triggered transmit stream/category measurement. Such a QoS AP receiving a triggered transmit stream/category measurement request shall give an incapable indication. The number of simultaneous triggered transmit stream/category measurements supported at a QoS STA is outside the scope of the standard. A STA shall respond to further requests with a refused indication if the number of simultaneous triggered QoS measurements supported by the STA is reached.

If `dot11RMTriggeredTransmitStreamCategoryMeasurementActivated` is true, a QoS STA shall accept a triggered Transmit Stream/Category Measurement and shall reject it otherwise. A QoS STA accepting a triggered QoS measurement shall measure the requested TC or TS. If a trigger condition occurs, the measuring QoS STA shall send a Transmit Stream/Category Measurement report to the requesting QoS STA. The measuring QoS STA shall not send further triggered QoS reports until the Trigger Timeout period specified in the request has expired or new trigger conditions have been requested. Measurement of transmit stream/category metrics shall continue during the reporting timeout period. Reporting shall resume following the Trigger Timeout period, or immediately following the acceptance of new trigger conditions.

If a QoS STA receives a Transmit Stream/Category Measurement request for a TC, or TS that is already being measured using a triggered transmit stream/category measurement, the triggered traffic stream measurement shall be suspended for the duration of the requested traffic stream measurement. When triggered measurement resumes, the traffic stream metrics shall be reset.

Traffic stream metrics reported in a triggered transmit stream/category measurement report shall be the values accumulated over the number of successfully and unsuccessfully transmitted MSDUs prior to the trigger event given in the Measurement Count field of the transmit stream/category measurement request that established the trigger condition. It is possible that a consecutive or delay trigger event occurs after acceptance of a triggered transmit stream/category measurement but before the number of MSDUs in Measurement Count has been transmitted. In this case the report shall be the values accumulated since measurement started. The measurement count value appears in the Transmitted MSDU Count field of a triggered transmit stream/category measurement report. Measurement duration shall not be used in triggered QoS measurement, and the Measurement Duration field in both the Measurement Request and any Measurement Report shall be set to 0.

The Measurement Start Time field of a triggered transmit stream/category measurement report shall contain the value of the QoS STA TSF timer at the time the trigger condition occurred to an accuracy of 1 TU.

Once accepted by a measuring QoS STA, a triggered QoS measurement continues to be active until

- The relevant TS is deleted,
- The measuring QoS STA or QoS STA that requested the measurement disassociates or successfully reassociates, or
- The measurement is terminated by the requesting QoS STA.

All triggered QoS measurements shall be terminated at a measuring QoS STA by receiving a triggered transmit stream/category measurement request with the Enable bit equal to 1 and the Report bit equal to 0. A triggered QoS measurement request with no trigger conditions specified in the Trigger Conditions field shall terminate a triggered QoS measurement for the TC or TS specified in the request. A QoS STA requesting a triggered QoS measurement may update the trigger conditions by sending a triggered transmit stream/category measurement request specifying the new trigger conditions.

11.11.9.9 Location Civic report

If `dot11RMCivicMeasurementActivated` is true and civic location information is not available, the STA shall reject a Location Civic request by returning a Measurement Report frame including a Measurement Report element with the Refused bit set to 1. If `dot11RMCivicMeasurementActivated` is true and civic

location information is available, the STA shall respond with a Measurement Report frame including one Location Civic report.

A Location Civic request shall indicate a location request for the requesting STA, the reporting STA, or a third STA with the MAC address specified in the Target MAC address field, by setting the Location Civic request Location Subject field to indicate a Local, a Remote, or a third-party request respectively. Local Location Civic request is used by requesting STA to obtain its own location by asking “Where am I?” Remote Location Civic request is used by requesting STA to obtain location of the reporting STA by asking “Where are you?” Third-party Location request is used by requesting STA to obtain location of a STA with the MAC address specified in the Target MAC address field.

If dot11RMCivicMeasurementActivated is false, a STA that receives the received Location Civic request shall respond with a Location Civic report where the Incapable bit is set in the Measurement Report Mode field.

If dot11RM3rdPartyMeasurementActivated is false, a STA shall reject any LCI request that includes an LCI request with the Location Subject field equal to 2 by returning a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable bit set to 1.

It is optional for a STA to support a Location Civic request and a Location Civic report with the Location Subject field equal to 2. If dot11RM3rdPartyMeasurementActivated is true and a STA supports Location Civic request and Location Civic report, the following procedure shall be followed:

- When a non-AP STA requests the civic location of a STA with the MAC address specified in the Target MAC address field, it shall also include its own MAC address in the Originator Requesting STA MAC address field. When an AP receives a Location Civic request with the Location Subject field value equal to 2, the AP shall generate a Location Civic request to the STA with the MAC address specified in the Target MAC address field. If the AP does not have an association with the STA with the MAC address specified in the Target MAC address field, the AP shall reject the received Location Civic request by returning a Location Civic report where the Incapable bit is set in the Measurement Report Mode field. The AP shall copy the Originator Requesting STA MAC address and Target MAC address fields into the request from the received Location Civic request.
- When a STA receives a Location Civic request with the Location Subject field value equal to 2, the STA may generate a Location Civic report if the MAC address in the Target MAC address field is its own MAC address; it shall not generate a Location Civic report otherwise. When a Location Civic report is generated, the reporting STA shall include its MAC address into the Target MAC address field and the MAC address present in the Originator Requesting STA MAC address field of the corresponding Location Civic request into the Originator Requesting STA MAC address field. When an AP receives a Location Civic report with an Originator Requesting STA MAC address field present, the AP shall generate a Location Civic report to the associated STA with the MAC address specified in the Originator Requesting MAC address field. The AP shall copy the Originator Requesting STA MAC address and Target MAC address fields into the Location Civic report being transmitted to the originating requesting STA.

When a STA receives a Location Civic request with the subject field equal to 2, but does not support third-party location, it shall respond with a Radio Measurement Report frame including a Radio Measurement Report element with the Incapable bit set to 1.

If dot11RMCivicMeasurementActivated is true and a STA has its own location configured in civic format, excluding an unknown civic location as defined in 9.4.2.22.13, the STA shall set dot11RMCivicConfigured to true.

If `dot11RMCivicMeasurementActivated` is true and a STA has its own location available in one or more location formats, as defined in Table 9-100, and includes Civic Location Type field value 0, indicating “IETF RFC 4776,” it shall set the Civic Location field to 1 in the Extended Capabilities element.

NOTE—The Location Civic field’s size limit constrains the amount of information that can be carried.

If the Location Civic report contains the Location Reference and Location Shape subelements, the receiving STA may use the information specified in those subelements in combination with the Civic Location field value for additional granularity on the position reported in the Civic Location field.

If the Location Civic report contains the Map Image subelement, the receiving STA’s SME can retrieve the floor plan specified by the Map URL field. The method to retrieve the floor plan specified by the Map URL field is out of scope of this document.

11.11.9.10 Location Identifier report

The Location Identifier report provides the ability for a STA to receive one or more:

- Indirect URI references and forward a subset of those references to an external agent for the purposes of that agent gathering the STA’s location value. The protocol used to query for a location report based on the Public Identifier URI/FQDN provided in the Location Identifier report is indicated by the URI/FQDN Descriptor field.
- FQDNs, one per location server, that can be used to discover the location server and establish communications with it. The protocol used with the location server is indicated by the URI/FQDN Descriptor field.

If `dot11RMIdentifierMeasurementActivated` is true and location information is not available, the STA that receives a Location Identifier request shall respond with a Measurement Report frame including a Measurement Report element with the Incapable bit set to 1. If `dot11RMIdentifierMeasurementActivated` is true and location information is available, the STA shall respond with a Measurement Report frame including one Measurement Report element containing a Location Identifier report that carries one or more Public Identifier URI/FQDN subelements.

A Location Identifier request shall indicate a location request for the requesting STA, the reporting STA, or a third-party STA with the MAC address specified in the Target MAC address field, by setting the Location Identifier request Location Subject field to indicate a Local, a Remote, or a Third-party request respectively. Local Location Identifier request is used by requesting STA to obtain its own location by asking “Where am I?” Remote Location Civic request is used by requesting STA to obtain location of the reporting STA by asking “Where are you?” Third-party Location request is used by requesting STA to obtain location of a STA with the MAC address specified in the Target MAC address field.

If `dot11RM3rdPartyMeasurementActivated` is false, a STA that receives an LCI request that includes an LCI request with the Location Subject field equal to 2 shall respond with a Radio Measurement Report frame including an Radio Measurement Report element with the Incapable bit set to 1.

It is optional for a STA to support a Location Identifier request and a Location Identifier report with the Location Subject field equal to 2. If `dot11RM3rdPartyMeasurementActivated` is true and a STA supports Location Identifier request and Location Identifier report, the following procedure shall be followed:

- When a non-AP STA requests the location identifier of a STA with the MAC address specified in the Target MAC address field, it shall also include its own MAC address in the Originator Requesting STA MAC address field. When an AP receives a Location Identifier request with the Location Subject field value equal to 2, the AP shall generate a Location Identifier request to the STA with the MAC address specified in the Target MAC address field. If the AP does not have an association with the STA with the MAC address specified in the Target MAC address field, the AP shall reject the received Location Identifier request by returning a Location Identifier report where

the Incapable bit is set in the Measurement Report Mode field. The AP shall copy the Originator Requesting STA MAC address and Target MAC address fields into the request from the received Location Identifier request.

- When a STA receives a Location Identifier request with the Location Subject field value equal to 2, the STA may generate a Location Identifier report if the MAC address in the Target MAC address field is its own MAC address; it shall not generate a Location Identifier report otherwise. When a Location Identifier report is generated, the reporting STA shall include its MAC address into the Target MAC address field and the MAC address present in the Originator Requesting STA MAC address field of the corresponding Location Identifier request into the Originator Requesting STA MAC address field. When an AP receives a Location Identifier report with an Originator Requesting STA MAC address field present, the AP shall generate a Location Identifier report to the associated STA with the MAC address specified in the Originator Requesting MAC address field. The AP shall copy the Originator Requesting STA MAC address and Target MAC address fields into the Location Identifier report being transmitted to the originating requesting STA.

When a STA receives an Location Identifier request with the subject field equal to 2, but does not support third-party location, it shall respond with a Radio Measurement Report frame including a Radio Measurement Report element with the Incapable bit set to 1.

If `dot11RMIdentifierMeasurementActivated` is false, a STA shall reject the received Location Identifier request by returning a Location Identifier report where the Incapable bit is set in the Measurement Report Mode field.

If `dot11RMIdentifierMeasurementActivated` is true and a STA has its own location available in one or more location formats, as defined in Table 9-100, and includes Civic Location Type field value 0, indicating “IETF RFC 4776” or geospatial format that can be referenced by a location identifier, it shall set the Identifier Location field to 1 in the Extended Capabilities element.

11.11.9.11 Fine Timing Measurement Range report

The Fine Timing Measurement Range report provides a means for a requesting STA to request a responding STA that advertises FTM Range Report Capability Enabled equal to true in the RM Enabled Capabilities element to measure and report the ranges between the responding STA and other nearby APs where the ranges are determined using the FTM procedure (see 11.24.6).

If `dot11RMFineTimingMsmtRangeRepActivated` is true, `dot11FineTimingMsmtInitActivated` shall be true also.

If `dot11RMFineTimingMsmtRangeRepActivated` is false, a STA shall reject any Fine Timing Measurement Range request by responding with a Radio Measurement Report frame that includes a Measurement Report element with the Incapable field set to 1.

If a responding STA with `dot11RMFineTimingMsmtRangeRepActivated` equal to true accepts a Fine Timing Measurement Range request, then:

- If the request includes a maximum age subelement, and the STA has already determined FTM ranges to C APs listed in the Neighbor Report subelements field in the Measurement Request field within the indicated Maximum Age, then the STA may use these ranges instead of initiating new FTM procedures with the C APs. Define C_{sub} as the subset of APs selected by the STA from the C eligible APs.
- Considering the remaining listed APs in the Neighbor Report subelements field in the Measurement Request field, if Minimum AP Count exceeds C_{sub} , the responding STA shall wait a random delay up to the value of Randomization Interval field in the Measurement Request element (see 11.11.3) then initiate the FTM procedure with at least Minimum AP Count – C_{sub} remaining listed APs. The

responding STA should initiate the FTM procedure with the remaining listed APs until either the responding STA has successfully measured the range between the responding STA with at least Minimum AP Count APs or has attempted the FTM procedure with all remaining listed APs. For each FTM procedure that is attempted with a remaining listed AP without success, the responding STA shall record an error entry.

For procedures related to listed APs that operate on non-operating channels, see 11.11.2.

The responding STA shall transform the measurements obtained from each FTM procedure with an AP into a range and a maximum error between itself and the AP, while accounting for any clock offsets between the responding STA and the AP.

At the completion of all of the FTM procedures and transformations, the responding STA shall send the all computed range information between itself and other APs, and all error entries, to the requesting STA using a Measurement Report element with Measurement Type field set to Fine Timing Measurement Range in a Measurement Report frame.

A requesting STA may request a single set of range measurements by setting the Number of Repetitions field to 0 in the Measurement Request frame, or request a regular sequence of range measurements by

- setting the Number of Repetitions field greater than 0 in the Measurement Request frame, and
- including a Measurement Request element with Measurement Type field equal to Fine Timing Measurement Range and a Measurement Request element with Measurement Type field equal to Measurement Pause (see 11.11.9.7).

11.11.10 Usage of the neighbor report

11.11.10.1 General

A neighbor report is sent by an AP and it contains information on neighboring APs that are members of ESSs requested in the neighbor report request. A neighbor report might not be exhaustive either by choice, or due to the fact that there might be neighbor APs not known to the AP. The neighbor report contents are derived from the NeighborListSet parameter of the MLME-NEIGHBORREPRESP.request primitive. The mechanism by which the contents of this table are determined is outside the scope of this standard, but it may include information from measurement reports received from the STAs within the BSS, information obtained via a management interface, or the DS.

NOTE—The purpose of the neighbor report is to enable the STA to optimize aspects of neighbor service set transition and ESS operation. A Neighbor Report element contains information on APs that the STA might use as candidates for a service set transition. Since the information in the neighbor report might be stale, it is advisory; information obtained by the report recipient through a scan or other sources might also be considered, possibly overriding information in the neighbor report. For example, where information contained within a neighbor report is contradicted by information in a Measurement Pilot, Beacon, or Probe Response frame, that response information needs to take precedence.

An AP in which dot11RMNeighborReportActivated is false shall not transmit a Fine Timing Measurement Range request. An AP in which dot11RMNeighborReportActivated is false should not transmit a Measurement Request with the Measurement Type field equal to LCI and the Location Subject field of the LCI request set to Location Subject Remote.

11.11.10.2 Requesting a neighbor report

A STA requesting a neighbor report from an AP shall send a Neighbor Report Request frame to its associated AP.

A STA can request LCI information of an AP and its neighboring APs, if the AP advertises the FTM responder capability (Extended Capabilities element with the Fine Timing Measurement Responder field set to 1), the geospatial location capability (Extended Capabilities element with the Geospatial Location field set to 1), and the neighbor report capability (RM Enabled Capabilities element with the Neighbor Report

Capability Enabled field set to 1). A STA can request Civic Location information of an AP and its neighboring APs, if the AP advertises the FTM responder capability (Extended Capabilities element with the Fine Timing Measurement Responder field set to 1), the location civic capability (Extended Capabilities element with the Civic Location field set to 1), and the neighbor report capability (RM Enabled Capabilities element with the Neighbor Report Capability Enabled field set to 1).

To request the LCI of neighboring APs, the STA shall transmit a Neighbor Report Request frame that includes a Measurement Request element with the value of its Measurement Type field equal to LCI. To request the location civic of neighboring APs, the STA shall transmit a Neighbor Report Request frame that includes a Measurement Request element with the value of its Measurement Type field equal to Location Civic.

11.11.10.3 Responding to a neighbor report request

If `dot11RMNeighborReportActivated` is true, an AP receiving a neighbor report request shall respond with a Neighbor Report Response frame containing zero or more Neighbor Report elements. If an SSID element is specified in the corresponding Neighbor Report Request frame, the Neighbor Report element(s) shall contain information only concerning neighbor APs that are members of the current ESS identified by the SSID element contained within the neighbor report request. If the SSID element is omitted, the Neighbor Report element(s) shall contain information concerning neighbor APs that belong to the same ESS as the requesting STA. If the wildcard SSID element is specified in the corresponding Neighbor Request frame, the Neighbor Report element(s) shall contain information concerning all neighbor APs. If there are no neighbor APs available, the AP shall send a Neighbor Report Response frame with no Neighbor Report elements.

If `dot11RMNeighborReportActivated` is true and `dot11FineTimingMsmtRespActivated` is true, an AP receiving a neighbor report request shall respond with a Neighbor Report Response frame containing one or more Neighbor Report elements.

If `dot11RMNeighborReportActivated` is false in an AP receiving a neighbor report request, it shall ignore the request.

A serving AP shall include a TSF subelement in the Neighbor Report element if it is able to guarantee an accumulated error of 1.5 TU or better on the TSF Offset subfield. Otherwise, the AP shall not include a TSF subelement in the Neighbor Report element.

When the SSID element is omitted, the SSID element is specified by the wildcard SSID, or the SSID element is present and indicates the AP's own SSID and either of the following is true:

- An AP that has both `dot11FineTimingMsmtRespActivated` and `dot11RMLCIConfigured` equal to true receives a Measurement Request element with Measurement Type field equal to LCI.
- An AP that has both `dot11FineTimingMsmtRespActivated` and `dot11RMCivicConfigured` equal to true receives a Measurement Request element with Measurement Type field equal to Location Civic.

within a Neighbor Report Request frame then the AP shall include a Neighbor Report element for the AP's own BSSID in the Neighbor Report Response frame (i.e., in this case the Neighbor Report Response frame contains one or more Neighbor Report elements). If `dot11RMLCIConfigured` is equal to true, the Neighbor Report element shall include a Measurement Report subelement with the Measurement Type field equal to LCI. If `dot11RMCivicConfigured` is equal to true, the Neighbor Report element shall include a Measurement Report sub element with the Measurement Type field equal to Location Civic.

When both of the following are true:

- the SSID element specified in the Neighbor Report Request does not include the AP's own SSID and an AP that has at least one of `dot11FineTimingMsmtRespActivated` and

dot11RMLCIConfigured equal to false receives a Measurement Request element with the Measurement Type field equal to LCI within a Neighbor Report Request frame

- an AP that has at least one of dot11LciCivicInNeighborReport and dot11RMLCIConfigured equal to false receives a Neighbor Report Request frame

then the AP shall not include a Neighbor Report element containing a Measurement Report subelement with the Measurement Type field set to LCI describing the reporting AP in the Neighbor Report Response frame. In this case the Neighbor Report Response frame contains zero or more Neighbor Report elements.

When both of the following are true:

- the SSID element specified in the Neighbor Report request does not include the AP's own SSID and an AP that has at least one of dot11FineTimingMsmtRespActivated and dot11RMCivicConfigured equal to false receives a Measurement Request element with the Measurement Type field equal to Location Civic within a Neighbor Report Request frame
- an AP that has at least one of dot11LciCivicInNeighborReport and dot11RMCivicConfigured equal to false receives a Neighbor Report Request frame

then the AP shall not include a Neighbor Report element containing a Measurement Report subelement with Measurement Type set to Location Civic describing the reporting AP in the Neighbor Report Response frame (i.e., in this case the Neighbor Report Response frame contains zero or more Neighbor Report elements). In this case the Neighbor Report Response frame contains zero or more Neighbor Report elements.

NOTE—The Neighbor Report Response frame includes a list Neighbor Report elements one for each neighbor. The criteria for the selection of an AP as a neighbor AP is beyond the scope of this specification.

The Neighbor Report Response frame shall also include a Neighbor Report element for each neighbor AP.

When either of the following is true in a neighbor AP of the AP (reporting AP) that receives a Measurement Request element with the Measurement Type field equal to LCI within a Neighbor Report Request frame:

- the neighbor AP has both FTM responder capability (Extended Capabilities element with the Fine Timing Measurement Responder field set to 1) and LCI measurement capability (RM Enabled Capabilities element with the LCI Measurement Capability Enabled field set to 1)
- the reporting AP has dot11LciCivicInNeighborReport equal to true and the neighbor AP has LCI measurement capability (RM Enabled Capabilities element with the LCI Measurement Capability Enabled field set to 1)

then the reporting AP shall include a Neighbor Report element in the Neighbor Report Response frame. In addition if the neighbor AP has Geospatial Location capability (Extended Capabilities element with the Geospatial Location field set to 1), the Neighbor Report element shall include a Measurement Report subelement with Measurement Type equal to LCI. If the maximum horizontal or vertical location error of the neighbor AP relative to a reference AP is known to the AP and this relative error is smaller than the absolute error indicated in the LCI subelement, then the AP may include a Relative Location Error subfield in the Measurement Report field.

When either of the following is true in a neighbor AP of the AP (reporting AP) that receives a Measurement Request element with the Measurement Type equal to Location Civic within a Neighbor Report Request frame:

- The neighbor AP has both FTM responder capability (Extended Capabilities element with the Fine Timing Measurement Responder field set to 1) and civic location measurement capability (RM Enabled Capabilities element with Civic Location Measurement Capability Enabled set to 1)
- The reporting AP has dot11LciCivicInNeighborReport equal to true and the neighbor AP has civic location measurement capability (RM Enabled Capabilities element with Civic Location Measurement Capability Enabled set to 1)

then the reporting AP shall include a Neighbor Report element in the Neighbor Report Response frame. In addition if the neighbor AP has Civic Location (Extended Capabilities element with the Civic Location field set to 1), the Neighbor Report element shall include a Measurement Report subelement with the Measurement Type field equal to Location Civic.

Each Measurement Report subelement returned shall have the same Measurement Token value as in the Measurement Token field of the corresponding Measurement Request element, or if there is no corresponding Measurement Request then the Measurement Token value shall be set to 0.

If an AP determines that the LCI and/or civic location of a neighboring AP changes, the AP may send an unsolicited Neighbor Report Response frame containing complete neighbor information including the updated neighboring AP location information. The Dialog Token field is set to 0 as defined in 9.6.7.7.

A STA that receives an LCI report that contains a Usage Rules/Policy subelement shall process the LCI information in compliance with the retransmission and retention permissions in the Usage-rules subelement.

The Wide Bandwidth Channel subelement shall not be included in the Neighbor Report element when either the HT Operation subelement or the VHT Operation subelement is included in the Neighbor Report element.

A VHT AP in which dot11FineTimingMsmtRespActivated is true that transmits a Neighbor Report element containing an HT Operation subelement shall include a VHT Operation subelement in the Neighbor Report element.

A non-DMG AP in which dot11FineTimingMsmtRespActivated is true that transmits a Neighbor Report element containing neither an HT Operation subelement nor a VHT Operation subelement shall include a Wide Bandwidth Channel subelement in the Neighbor Report element.

11.11.11 Link Measurement

A STA may use a Link Measurement Request frame to request another STA to respond with a Link Measurement Report frame containing a TPC report element. If dot11RMLinkMeasurementActivated is true, a STA receiving a Link Measurement Request frame shall respond with a Link Measurement Report frame containing a TPC Report element indicating the power used to transmit the Link Measurement report. The Link Measurement report also contains antenna ID and signal quality (RCPI and RSNI).

If dot11RMLinkMeasurementActivated is false in an AP or PCP receiving a Link Measurement Request, it shall ignore the request.

11.11.12 Measurement of the RPI histogram

To compute RPI densities for an RPI Histogram report (see 9.4.2.22.4), the STA shall measure the received power level on the specified channel, as detected at the antenna connector, as a function of time over the measurement duration. The maximum tolerance of the received power measurements shall be ± 5 dB. Furthermore, the received signal power measurement should be a monotonic function of the actual power at the antenna. The time resolution of the received power measurements is in microseconds. The received power measurements are converted to a sequence of RPI values by quantizing the measurements according to Table 9-108. The RPI densities are then computed for each of the eight possible RPI values using

$$\text{RPI Density} = \left\lceil \frac{255 \times D_{RPI}}{1024 \times D_M} \right\rceil$$

where

- D_{RPI} is the duration receiving at the specified RPI value (μs)
- D_M is the measurement duration (TU).

The sum of the RPI densities is approximately 255, but could be up to 262 because of rounding effects.

11.11.13 Operation of the Max Transmit Power field

The maximum tolerance for the value reported in Max Transmit Power field shall be 5 dB. The value of the Max Transmit Power field shall be less than or equal to the Max Regulatory Power value for the current channel.

11.11.14 Multiple BSSID set

A multiple BSSID set is characterized as follows:

- All members of the set use a common operating class, channel, Channel Access Functions, and antenna connector.
- The set has a maximum range of 2^n for at least one n, where $1 \leq n \leq 46$.
- Members of the set have the same 48-n MSBs in their BSSIDs.
- All BSSIDs within the multiple BSSID set are assigned in a way that they are not available as MAC addresses for STAs using a different operating class, channel or antenna connector.

NOTE—For example, if the APs within BSSs with BSSIDs 16, 17, and 27 share the operating class, channel and antenna connector, and the range of MAC addresses from 16–31 inclusive are not assigned to other STAs using a different antenna connector, then the BSSIDs 16, 17, and 27 are members of a multiple BSSID set. The set is described by $n = 4$ ($2^n = 16$) with BSSIDs in the range 0x00000000001X. The set cannot be described by $n = 8$ for instance since at least one of the BSSIDs in the range 0x0000000000XX might be used as a BSSID by an AP that does not share the same operating class, channel, and antenna connector.

When the multiple BSSID set contains two or more members, the transmission of Measurement Pilots is constrained as described in 11.11.15.

A Multiple BSSID element, with or without optional subelements, indicates that all APs and PCPs within the indicated range of BSSIDs transmit using a common class, channel, and antenna connector.

A single Beacon frame may contain elements for the multiple BSSID set members; see 11.1.3.8.

11.11.15 Measurement Pilot frame generation and usage

11.11.15.1 General

The Measurement Pilot frame is a compact Action frame transmitted pseudo-periodically by an AP at a small interval relative to a Beacon Interval. The Measurement Pilot frame provides reduced information relative to a Beacon frame to allow for the required small interval. The purpose of the Measurement Pilot frame is to assist a STA with the following functions:

- Rapid discovery of the existence of a BSS via passive scanning
- Rapid collection of neighbor AP signal strength measurements via passive scanning
- Enable transmission of a Probe Request frame

A STA's dot11RMMeasurementPilotActivated determines the level of support for measurement pilot at the STA. Table 11-10 describes permitted values for dot11RMMeasurementPilotActivated and what they signify.

Table 11-10—Measurement pilot activated definition

| Device function | dot11RM-MeasurementPilot Activated | Notes | | | | | | | | | | | | |
|-------------------|------------------------------------|---|---|----------------------------------|---|----------------|---|-----------------|---|-----------------|---|-----------------|---|-----------------|
| AP and non-AP STA | 0 | If the STA is contained within an AP, it does not generate MPs and if the device is a non-AP STA, it ignores the MPs it receives | | | | | | | | | | | | |
| AP and non-AP STA | 1 | If the STA is contained within an AP, it can transmit MPs, and if the device is a non-AP STA, it can receive the MPs and can use the information contained in MPs. | | | | | | | | | | | | |
| Non-AP STA | 2 | The non-AP STA is making use of the MPs it receives or would receive if they were being transmitted. | | | | | | | | | | | | |
| Non-AP STA | 3–7 | Reserved | | | | | | | | | | | | |
| AP | | <p>The AP is transmitting MPs and using the information contained in them, and the AP is actively transmitting MPs with MP interval set to a value within the range as shown below.</p> <p>MP Interval with respect to Beacon Interval:</p> <table> <tr> <td>2</td><td>> 3% and < 5% of Beacon Interval</td></tr> <tr> <td>3</td><td>≥ 5% and < 10%</td></tr> <tr> <td>4</td><td>≥ 10% and < 15%</td></tr> <tr> <td>5</td><td>≥ 15% and < 20%</td></tr> <tr> <td>6</td><td>≥ 20% and < 25%</td></tr> <tr> <td>7</td><td>≥ 25% and < 50%</td></tr> </table> | 2 | > 3% and < 5% of Beacon Interval | 3 | ≥ 5% and < 10% | 4 | ≥ 10% and < 15% | 5 | ≥ 15% and < 20% | 6 | ≥ 20% and < 25% | 7 | ≥ 25% and < 50% |
| 2 | > 3% and < 5% of Beacon Interval | | | | | | | | | | | | | |
| 3 | ≥ 5% and < 10% | | | | | | | | | | | | | |
| 4 | ≥ 10% and < 15% | | | | | | | | | | | | | |
| 5 | ≥ 15% and < 20% | | | | | | | | | | | | | |
| 6 | ≥ 20% and < 25% | | | | | | | | | | | | | |
| 7 | ≥ 25% and < 50% | | | | | | | | | | | | | |

11.11.15.2 Measurement Pilot frame generation by an AP

The AP shall determine if it is a member of a multiple BSSID set with two or more members. If so, at most one AP of the multiple BSSID set shall have dot11RMMeasurementPilotActivated set to a value between 2 and 7. How this occurs is out of scope of this standard.

If dot11RMMeasurementPilotActivated is between 2 and 7, the following statements apply:

- If the AP is a member of a multiple BSSID set with two or more members, then the BSSIDs of all members of the multiple BSSID set shall be indicated in the Beacon and Probe Response frames by the Multiple BSSID subelement.
- The AP shall maintain a Measurement Pilot frame generation function, which transmits Measurement Pilot frames at a basic rate according to dot11RMMeasurementPilotPeriod.
- The AP defines a series of TMPTTs exactly dot11RMMeasurementPilotPeriod apart. A TMPTT arrives when the AP's local TSF timer (in μ s) modulo the Measurement Pilot Interval equals 0.
- At each TMPTT, the AP shall schedule a Measurement Pilot frame as the next frame for transmission ahead of other queued frames using the AC_VO EDCA parameters unless the TMPTT satisfies:

$$TBTT - \frac{T_{MPP}}{2} \leq TMPTT < TBTT + \frac{T_{MPP}}{2}$$

where T_{MPP} is dot11RMMeasurementPilotPeriod, for any TBTT of members of the multiple BSSID set, in which case the AP shall not generate the Measurement Pilot. This is illustrated in

Figure 11-28. How the AP determines the TBTTs of members of the multiple BSSID set is out of scope of this standard.

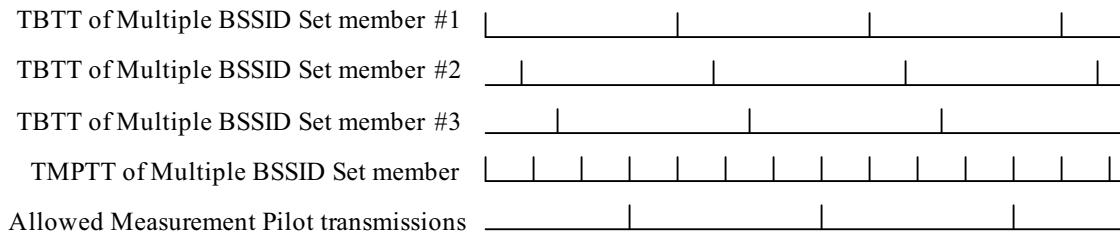

Figure 11-28—Example of Measurement Pilot frame scheduling

In case the medium is determined by the carrier-sense mechanism (see 10.3.2.1) to be unavailable at the TMPTT, the AP shall delay the actual transmission of a Measurement Pilot frame according to the basic medium access rules specified in Clause 10 for a maximum period of one dot11RMMeasurementPilotPeriod and drop the delayed Measurement Pilot frame at the next TMPTT. In this way, a continuously busy medium causes multiple successive Measurement Pilots to be delayed, then dropped. An AP shall transmit Measurement Pilots to the broadcast address. An AP shall not retransmit or buffer Measurement Pilots as part of the PSP mechanisms.

- If the AP is a member of a multiple BSSID set with two or more members, then the BSSIDs of all members of the multiple BSSID set shall be indicated in the Measurement Pilot frame using the Multiple BSSID subelement.

NOTE 1—APs are advised to enable Measurement Pilots judiciously due to the possibility of excessive medium time being consumed by Measurement Pilots from multiple overlapping APs. For instance dot11RMMeasurementPilotTransmissionInformationActivated might be set to false:

- a) When enabling Measurement Pilots would cause:
 - 1) More than 10% of the medium time at the AP to be consumed by beacons and Measurement Pilots transmitted by any source, or
 - 2) More than 5% of the medium time at the AP to be consumed by Measurement Pilots transmitted by any source.
- b) When STAs are not expected to be using Measurement Pilots. How this is determined is out of the scope of this standard, but may depend upon many STAs setting the Measurement Pilot Capability field in the RM Enabled Capabilities element to 0 or 1 upon association at any member of the multiple BSSID set recently or at similar times in the past.
- c) When all members of the multiple BSSID set are within ESSs that contain one BSS only.
- d) When the AP's operating regulatory domain is not subject to DFS regulations.
- e) When the AP's operating regulatory domain is subject to DFS regulations but compliance with the regulations is impaired by Measurement Pilots.
- f) When the number of channels valid for the AP's operating regulatory domain or frequency band is small.
- g) When no members of the multiple BSSID set are located at ingress or egress points of an ESS, so are less useful for roaming between an IEEE 802.11 ESS and other networks.

NOTE 2—For efficient use of the medium, it is recommended that Measurement Pilots not be sent using a PHY specified in Clause 15 or Clause 16.

An AP that is not extended spectrum management capable shall not include a Wide Bandwidth Channel Switch subelement in a Measurement Pilot frame. If the Wide Bandwidth Channel Switch subelement is included in a Measurement Pilot frame, then the Operating Class shall include a 40 MHz channel spacing.

11.11.15.3 Measurement pilot usage by a STA

Whenever testing a requested BSSID for equality against the BSSID of a Measurement Pilot, the following statements apply:

- If the Measurement Pilot frame does not contain the Multiple BSSID element, then equality shall be true if the requested BSSID equals the BSSID of the Measurement Pilot frame, and otherwise false.
- If the Measurement Pilot frame contains the Multiple BSSID element, and the requested BSSID is a non-wildcard BSSID, then equality shall be true if the requested BSSID equals any BSSID indicated by the Multiple BSSID element present in the Measurement Pilot, and otherwise false.
- If the Measurement Pilot frame contains the Multiple BSSID element, and the requested BSSID is the wildcard BSSID, then equality shall be true.

NOTE—STAs are advised that due to considerations such as those noted in the prior subclause, APs might not transmit Measurement Pilots at all times or in all bands.

11.11.16 Access Delay Measurement

Access delay is measured by the AP's or PCP's MAC layer being the average medium access delay for transmitted frames measured from the time the MPDU is ready for transmission (i.e., begins CSMA/CA access or SP access, as appropriate) until the actual frame transmission start time. Access delay measurement results are included in the BSS Average Delay element and in the BSS AC Access Delay element.

For the BSS Average Delay measurement, the AP or PCP shall measure and average the medium access delay for all transmit frames using the DCF or EDCAF over a continuous 30 s measurement window. For the infrastructure BSS AC Access Delay measurement, the QoS AP or PCP shall measure and average the medium access delay for all transmit frames of the indicated AC (see Figure 9-308) using EDCA mechanism over a continuous 30 s measurement window. The accuracy for the average medium access delay shall be $\pm 100 \mu\text{s}$ or better when averaged over at least 200 frames. Accuracy is not defined for measurements averaged over less than 200 frames.

11.11.17 BSS Available Admission Capacity

BSS Available Admission Capacity provides a means for an AP to advertise admission capacity available for explicit admission control in any UP or AC. This information may assist STAs in making service set transition decisions.

The transmitted BSS Available Admission Capacity value represents a proportion of time on the wireless medium scaled linearly in units of 32 $\mu\text{s}/\text{s}$ from 0 (0% available time) to 31 250 (100% available time). If an AP transmits a BSS Load element, the values for any transmitted BSS Available Admission Capacity values shall be less than or equal to the Available Admission Capacity field value of the BSS Load value. If an AP transmits a BSS Available Admission Capacity element, the transmitted values should be current or recently calculated. The AP recalculates Available Admission Capacity values according to local policy. An Available Admission Capacity value of 0 transmitted in the BSS Available Admission Capacity element indicates that no admission capacity is available at the calculation time and that no explicit admissions can be granted by the AP for that UP or AC unless additional capacity becomes available. An AP that receives a TSPEC admission request for total medium time (in both directions, if applicable) that is less than or equal to the current available admission capacity for the requested UP or AC local policy may apply additional local policy before admitting the requested TSPEC.

NOTE 1—Available Admission Capacity values are dynamic in a BSS and the transmitted values cannot always reflect the actual values currently used by the AP for explicit admission control. Thus an AP should recalculate the Available Admission Capacity values regularly or after changes in the environment or the admitted capacity.

NOTE 2—STAs are advised that requesting admission for any TSPEC at an UP or AC that requires more medium time than is reported as available for the requested UP or AC is possible yet unlikely to be successful.

11.11.18 AP Channel Report

The AP Channel Report element contains a list of channels in an operating class where a STA is likely to receive the Beacon or Probe Response frames sent by an AP, excluding the AP transmitting the AP Channel report. An AP Channel Report element only includes channels that are valid for the regulatory domain in which the AP transmitting the element is operating and consistent with the Country element in the frame in which it appears. One AP Channel Report element is included in the Beacon frame for each regulatory domain, which includes channels on which a STA is likely to receive the Beacon or Probe Response frames sent by an AP.

The contents of the AP Channel Report elements may be compiled from the list of unique operating/channel pairs found in the neighbor report. The contents of the AP channel report may be configured or obtained by other means beyond the scope of this standard.

11.11.19 Multicast diagnostic reporting

Multicast diagnostic reporting enables an AP to collect statistics on group addressed traffic at associated STAs. The method an AP uses to determine the multicast groups to which an associated STA is a member of is outside the scope of the standard and is typically performed by higher layer protocols. The Multicast Diagnostic request and Multicast Diagnostic report are defined in 9.4.2.21.13 and 9.4.2.22.12, respectively.

A STA whose dot11MulticastDiagnosticsActivated is true shall support multicast diagnostics reporting and shall set to 1 the Multicast Diagnostics field of the Extended Capabilities elements that it transmits. When the Multicast Diagnostics field in the Extended Capabilities field is 1, the Incapable bit in the Measurement Report Mode field of a Multicast Diagnostic report shall not be set to 1.

Multicast diagnostic reporting may use the triggered autonomous reporting capability described in 11.11.8.

The Measurement Start Time field of a triggered diagnostic report shall contain the value of the STA TSF Timer at the time the trigger condition started to occur to an accuracy of ± 1 TU.

An AP may send a Multicast Diagnostic request consisting of one or more Multicast Diagnostic requests in a Radio Measurement Request frame to a non-AP STA that has indicated support of the multicast diagnostic capability or to a multicast group address if all associated non-AP STAs support the multicast diagnostic capability. If the STA accepts the request it shall count the number of received MSDUs with the specified group address and the STA shall record the maximum observed PHY data rate of the frames that contained these MSDUs during the requested Measurement Duration. These two values shall be returned in a Multicast Diagnostic report in a Radio Measurement Report frame, as defined in 9.4.2.22.12. A non-AP STA shall not transmit a Radio Measurement Request frame containing a Multicast Diagnostic request. A STA shall not respond to a Radio Measurement Request frame containing a Multicast Diagnostic request received from a STA other than the AP with which it is associated.

An AP may request that triggered multicast diagnostic reporting be enabled at associated non-AP STAs that have indicated support of the multicast diagnostic capability. To enable multicast diagnostic reporting, the AP shall send a Measurement Request element containing the Request Type field set to Multicast Diagnostics and with the Enable and Report bits set to 1 within a Radio Measurement Request frame. See 11.11.8. For triggered multicast diagnostic reporting, the Multicast MAC Address and trigger conditions for diagnostic reporting shall be specified in the request.

Multicast diagnostic reporting may be requested for broadcast traffic by setting the Multicast MAC Address field to the broadcast address.

A non-AP STA accepting a request for triggered multicast diagnostic reporting shall send a Multicast Diagnostics report to the requesting STA if the specified trigger condition occurs. The measuring non-AP

STA shall not send further triggered Multicast Diagnostics reports until the period specified in the Reactivation Delay field in the Multicast Diagnostic Request has expired, or the non-AP STA receives a revised trigger condition from a Multicast Diagnostic Request. To prevent generation of too many triggered reports, the minimum value of the Reactivation Delay field shall be set to a value greater or equal to A STA's MinTriggerTimeout.

Once accepted, Multicast Diagnostic reporting continues to be active for the specified Multicast MAC address until one of the following occurs:

- The STA receives a Measurement Request element containing a Multicast Diagnostic Request Type and with the Enable bit equal to 1 and the Report bits equal to 0 within a Radio Measurement Request frame.
- Receipt of a Measurement Request element containing a Multicast Diagnostic Request Type, with the Enable and Report bits equal to 1, but with no trigger conditions.
- The STA leaves the Multicast Group or disassociates.
- The STA sends a Measurement Report element with the Measurement Result bit set to 1.

The STA shall maintain an inactivity timer for every multicast diagnostic request accepted by the STA in which the Inactivity Timeout Request field is 1. When a timeout of the inactivity timer is detected, the STA shall send a multicast diagnostic report with the inactivity Timeout Trigger field in the Multicast Reporting Reason field set to 1. The inactivity timer at a recipient is reset when MSDUs corresponding to the monitored group address are received.

A STA that declines a request for triggered multicast diagnostic reporting sends a Measurement Report element (as described in 9.4.2.22) in a Radio Measurement Report frame (as described in 9.6.2.3) with the Measurement Report Mode field set appropriately to indicate the reason for a failed or rejected request.

11.11.20 CCA request and report

The response to a CCA request is a CCA report. A STA may support the generation of a CCA report. A STA may generate a CCA report in response to a CCA request.

11.11.21 RPI Histogram request and report

The response to an RPI Histogram request is an RPI histogram report. A STA may support the generation of an RPI histogram. A STA may generate an RPI histogram report in response to an RPI Histogram request.

11.12 DSE procedures

11.12.1 General

Regulations that apply to the U.S. 3650 MHz band require enabling STAs to implement a mechanism to enable mobile and portable STA operation. Similar regulations exist in other regulatory domains. This standard describes such a mechanism, referred to as *dependent STA enablement (DSE)*.

Subclause 11.12 describes DSE procedures that can be used to satisfy the U.S. 3650 MHz band and similar regulatory requirements. Regulations that apply to the U.S. 3650 MHz band require fixed STAs and enabling STAs to have their operating locations registered. Licensees with STAs suffering or causing harmful interference are expected to cooperate and resolve problems by mutually satisfactory arrangements. The DSE procedures provide the location of the enabling STA and unique identifiers to assist licensees in the resolution of interference issues. The DSE procedures might also satisfy needs in other frequency bands and be useful for other purposes.

A STA shall use the DSE procedures defined in this subclause if `dot11LCIDSERequired` is true. `dot11DSERequired` and `dot11ExtendedChannelSwitchActivated` shall be true when regulatory authorities require DSE, with the following exceptions: `dot11DSERequired` shall be set to false to configure STAs to operate as registered STAs, and `dot11ExtendedChannelSwitchActivated` may be set to false when operating as a fixed STA. A summary of STA attributes and these MIB attributes are shown in Table 11-11.

Table 11-11—DSE STA attributes

| Type of STA | Registered STA | <code>dot11LCIDSERequired</code> and <code>dot11LCIDSEImplemented</code> | <code>dot11ExtendedChannelSwitchActivated</code> | <code>dot11DSERequired</code> |
|---------------|----------------|--|--|-------------------------------|
| Fixed STA | Yes | true | true or false | false |
| Enabling STA | Yes | true | true | false |
| Dependent STA | No | true | true | true |

A fixed STA is a registered STA that broadcasts its registered location and is restricted from enabling other STAs (see 11.12.3). An enabling STA is a registered STA that broadcasts its registered location, and regulatory authorities permit it to enable operation of unregistered STAs (see 11.12.4). A dependent STA is an unregistered STA that operates under the control of an enabling STA (see 11.12.5). When management frame protection is negotiated, stations shall use Protected Dual of Public Action frames instead of individually addressed Public Action frames for DSE procedures.

The DSE procedures provide for the following:

- Registered STA operation
- Creation of a DSE service area for dependent STA operation
- Dependent STA operation with DSE

11.12.2 Enablement and deenablement

11.12.2.1 General

This subclause describes the procedures used for IEEE 802.11 enablement and deenablement. A STA keeps a state variable for each STA with which enablement communication is needed:

- Enablement state with a value of *unenabled* or
- Enablement state with a value of *enabled*

NOTE—Refer to 11.12.5 for description of dependent STA operation in either enablement state.

Enablement utilizes a two-frame transaction sequence. The first frame asserts identity and requests enablement. The second frame returns the enablement result. In the description in 11.12.2.2 and 11.12.2.3, the STA initiating the enablement is referred to as *enablement requester*, and the STA to which the initial frame in the exchange is addressed is referred to as *enablement responder*. The specific items in each of the frames described in the following subclauses are defined in 9.6.8.4 and 9.6.8.5. An enabling STA may decline to enable a requesting STA. If the result is “successful,” the requesting STA shall be enabled.

Deenablement utilizes a one-frame transaction sequence. In the description in 11.12.2.4 and 11.12.2.5, the STA initiating the deenablement is referred to as *deenablement requester*, and the STA to which the frame is addressed is referred to as *deenablement responder*.

11.12.2.2 Enablement requester STA

Upon receipt of an MLME-ENABLEMENT.request primitive, the enablement requester STA shall perform the following procedure:

- a) Construct and transmit a DSE Enablement frame requesting enablement.
 - 1) Specific information items in the enablement frame are as follows.
 - i) STA identity assertion (in RequesterSTAAddress)
 - ii) Enabling STA identity assertion (in ResponderSTAAddress)
 - iii) Reason result code = 2
 - iv) Enablement identifier = 0
 - 2) Specific items in the enablement frame sent by the enablement responder STA are described in 11.12.2.3.
- b) On receipt of a matching DSE Enablement frame (i.e., the Requester STA Address and Responder STA Address match the pending request) that acknowledges the DSE Enablement frame, issue an MLME-ENABLEMENT.confirm primitive to inform the SME of the result of the enablement.
 - 1) The primitive may contain information from an DSE Enablement frame received from the enabling STA (see 11.12.2.3), or it may be issued for another reason (see 9.6.8.4).
 - 2) The reason result code in the enablement confirmation frame indicates when the enablement is successful.
 - 3) If the enablement was successful, the enablement state variable for the enablement responder STA shall be set to Enabled.
- c) If no matching DSE Enablement frame is received for the DSE Enablement frame within a period of EnablementTimeLimit TUs measured from the receipt of the MLME-ENABLEMENT.request primitive, issue an MLME-ENABLEMENT.confirm primitive with ResultCode set to TIMEOUT.

11.12.2.3 Enablement responder STA

Upon receipt of a Public Action DSE Enablement frame with a reason result code of 2, the enablement responder STA may enable the enablement requester STA using the following procedure:

- a) Create and transmit a response frame with the enablement status as defined in 9.6.8.4 set in the Reason Result Code field and with a dependent enablement identifier chosen to be unique among all dependent enablement identifiers that have been assigned if enablement was successful. The enablement responder shall transmit the ResultCode parameter from the .confirm primitive mapped as specified in Table 9-310 of 9.6.8.4 to indicate the result of the enablement request.
 - 1) Specific information items in the enablement frame response are as follows:
 - i) STA identity assertion (in RequesterSTAAddress)
 - ii) Enabling STA identity assertion (in ResponderSTAAddress)
 - iii) The result of the requested enablement as defined in 9.6.8.4
 - iv) Enablement identifier
- b) Issue an MLME-ENABLEMENT.indication primitive to inform the SME of the enablement.
 - 1) If the enablement is successful, the enablement state variable for the enablement requester STA shall be set to Enabled.

11.12.2.4 Deenablement requester STA

Upon receipt of an MLME-DEENABLEMENT.request primitive, the deenablement requester STA shall create and transmit a DSE Deenablement frame to the deenablement responder STA. Specific information items in the deenablement frame are as follows:

- a) Enabling STA identity assertion (in RequesterSTAAddress)

- b) STA identity assertion (in ResponderSTAAddress)
- c) Reason result code = 2

11.12.2.5 Deenablement responder STA

Upon receipt of a DSE Deenablement frame, the deenablement responder STA shall deenable with the deenablement requester STA by issuing an MLME-DEENABLEMENT.indication primitive to inform the SME of the deenablement. The enablement state variable for the deenablement requester STA shall be set to Unenabled.

11.12.3 Registered STA operation

A registered STA shall have dot11DSERequired equal to false. They shall transmit the DSE Registered Location element in every Beacon frame and shall set the Dependent STA bit in the DSE Registered Location element to 0. If the registered STA is located within a national policy area, such as a Fixed Satellite Service exclusion zone, or within an international agreement area near a national border, the RegLoc Agreement bit in the DSE Registered Location element shall be set to 1, signifying to other STAs that additional restrictions on STAs with directional antennas may apply; otherwise, it shall be set to 0.

The Latitude, Longitude, and Altitude fields of the DSE Registered Location element shall be reported at their best known resolutions, which might exceed the resolutions required by regulatory authorities. The Altitude Type field value shall be 3 (i.e., height above ground is in meters or, in other words, the altitude is in meters above adjacent terrain), unless another altitude type is required for operation in the regulatory domain. The Datum field value shall be 1 (World Geodetic System 1984), unless another datum is required for operation in the regulatory domain.

An enabling STA is a registered STA that broadcasts its registered location, and regulatory authorities permit it to enable operation of unregistered STAs (see 11.12.4). A dependent STA is an unregistered STA that operates under the control of an enabling STA (see 11.12.5).

A fixed STA is a registered STA that broadcasts its registered location and is restricted from enabling other STAs. A fixed STA shall have dot11LCIDSERequired set to true, and dot11ExtendedChannelSwitchActivated may be true or false. A fixed STA shall set dot11RegLocDSE to false and the RegLoc DSE bit in the DSE Registered Location element to 0, signifying that it is not creating a DSE service area. A fixed STA may operate in an infrastructure BSS or IBSS. A registered STA that is not an enabling STA may operate as an AP and relay Public Action frames (specifically, DSE Enablement, DSE Deenablement, DSE Measurement Request, DSE Measurement Report, DSE Power Constraint) from a dependent STA to its enabling STA. The specification of the algorithm by which Public Action frames are relayed is beyond the scope of this standard. Note that the enabling signal is not a Public Action frame and is not relayed (see 11.12.4).

11.12.4 Enabling STA operation with DSE

A registered STA may create and manage a DSE service area for dependent STA operation where regulatory requirements permit. A registered STA operating in this manner is referred to as an *enabling STA*. An enabling STA sets dot11RegLocDSE to true and signifies the creation of a DSE service area by setting the RegLoc DSE bit in the DSE Registered Location element to 1. Dependent STA transmission of any frames is conditional on receiving directly over the air and decoding a DSE Registered Location element with RegLoc DSE bit equal to 1, sent from an enabling STA. Before attempting enablement with any one enabling STA, a dependent STA may have detected several enabling STAs, may attempt enablement with one and fail, and then attempt enablement with another. An enabling STA shall assign dependent enablement identifiers in a way that makes them unique among STAs enabled by this enabling STA to help identify sources of interference.

An enabling STA may issue a DSE measurement request to any of its dependent STAs in order to receive a DSE measurement report that may have reported DSE LCI fields received from nearby STAs. The licensed operator may be able to use these reports to identify interfering STAs or map overlapping coverage in a multiple BSS situation. Because reported DSE LCI fields may refer to any destination address, a single DSE report may contain elements received from STAs that are not yet associated with a BSS.

An enabling STA may issue an ECS announcement to any of its dependent STAs in order to have their radio operation changed in frequency, channel bandwidth, and other operational parameters. A dependent AP or DFS owner with dot11DSERequired true and receiving an ECS announcement from its enabling STA shall perform the extended channel switching procedure as specified in 11.10.

An enabling STA may issue a DSE power constraint announcement to any of its dependent STAs in order to have their transmit power reduced from the regulatory limit. A dependent AP or DFS owner with dot11DSERequired true and receiving a DSE power constraint announcement from its enabling STA shall perform the power constraint procedure as specified in 11.12.5.

11.12.5 Dependent STA operation with DSE

A dependent STA shall set dot11DSERequired to true.

A typical state machine implementation of dependent STA operation with DSE is provided in Figure 11-29.

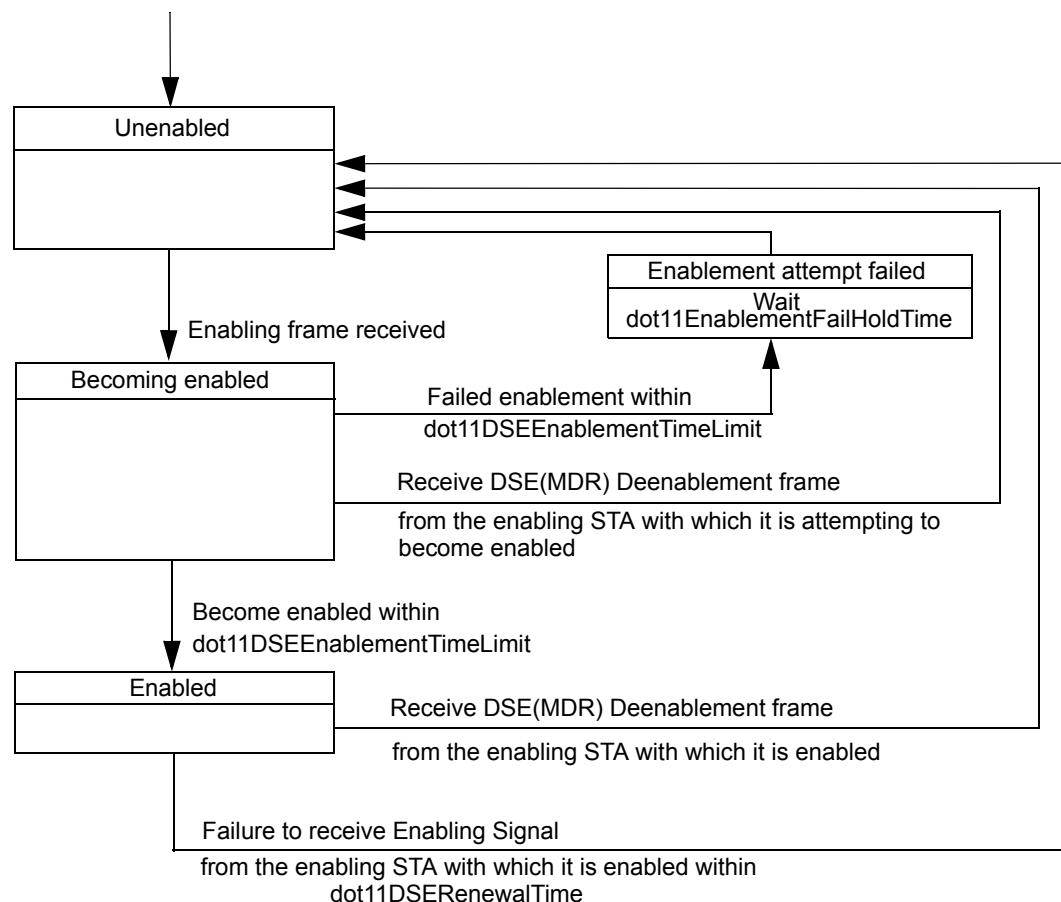

Figure 11-29—Dependent STA state machine

For DSE, the following statements apply:

- A STA with dot11DSERequired true shall not transmit any frames unless it has received a Beacon frame from an enabling STA with the Spectrum Management bit equal to 1 in the Capability Information field and with the RegLocDSE bit equal to 1 in the DSE Registered Location element. A dependent STA that is not enabled shall not transmit, except to attain enablement with an enabling STA, unless such action is mandated to be allowed in the regulatory domain (e.g., emergency services).
- A dependent STA shall not attempt enablement with an enabling STA unless the enabling STA is transmitting Beacon frames with the RegLoc DSE bit equal to 1 in the DSE Registered Location element.
- A dependent STA creates a dependent DSE Registered Location element containing the enabling STA's DSE Registered Location element and having the RegLoc DSE bit set to 0 and the Dependent STA bit set to 1. Before enablement, the Dependent Enablement Identifier field shall be set to 0. Upon attaining enablement, the Dependent Enablement Identifier field shall be set to the dependent enablement identifier value received by the dependent STA from the enabling STA in the MLME-ENABLEMENT.response primitive.
- The dependent STA shall send a Public Action DSE Registered Location Announcement frame to the broadcast address whenever the sum of dot11TransmittedFragmentCount, dot11GroupTransmittedFrameCount, and dot11ReceivedFragmentCount, modulo dot11DSETransmitDivisor equals 0, possibly delayed by the completion of the sending of the frames of the current MSDU or MMPDU or by the completion of the current transmission opportunity (TXOP).
- A dependent STA that has not attained enablement shall not transmit beyond dot11DSEEnablement-TimeLimit (in seconds), measured from the time of the first PHY-TXSTART.request primitive, while attempting to attain enablement. Then if it is not enabled, it shall not transmit for dot11DSEEnablementFailHoldTime (in seconds), before it again attempts to attain enablement.
- A dependent STA receiving a DSE Deenablement frame with the RequesterSTAAddress field matching the enabling STA with which it last attempted enablement and the ResponderSTAAddress field matching its own IEEE MAC address shall change its enablement state with the enabling STA to unenabled and set all fields of its DSE Registered Location Information field (see 9.4.2.52) to 0.
- A dependent STA shall return a DSE measurement report in response to a DSE measurement request if the request is received from the AP with which it is associated or the enabling STA with which it last attempted enablement and the ResponderSTAAddress field matches its own IEEE MAC address. The result may be the completed measurement or an indication that the STA is unable to complete the measurement request. A STA shall report it is too late to undertake a measurement request if it receives the request after the specified starting time for the measurement. The Measurement Report Mode field of a frame that is sent in response to a DSE Measurement Request frame shall not contain a value of 1 for the Incapable subfield and shall not contain a value of 1 for the Refused subfield of the Measurement Report Mode field of the DSE measurement report.
- A dependent STA receiving an ECS frame from the enabling STA with which it last attempted enablement or an ECS element from the AP with which it is associated shall perform the ECS procedure (see 11.10.3).
- A dependent STA receiving a DSE Power Constraint frame with the RequesterSTAAddress field matching the enabling STA with which it last attempted enablement and the ResponderSTAAddress field matching its own IEEE MAC address shall constrain its transmit power to be less than or equal to the maximum transmit power level specified for the current channel in the Country element minus the local power constraint specified in the DSE Power Constraint frame.
- An enabled dependent STA shall cease transmission within dot11DSERenewalTime (in seconds) if it has not received either a Beacon frame or a Probe Response frame from its enabling STA with the RegLoc DSE bit equal to 1 in the DSE Registered Location element. It shall then change its

enablement state with the enabling STA to unenabled and set all fields of its DSE Registered Location Information field (see 9.4.2.52) to 0.

11.13 Group addressed robust management frame procedures

When management frame protection is negotiated, the MLME shall provide an encapsulation service for group addressed robust Management frames. All group addressed robust Management frames shall be submitted to this service for encapsulation and transmission.

For group addressed Management frames that are specified with “Yes” in the “Group Addressed Privacy” column of Table 9-47, the group addressed frame protection service shall take the following actions:

- The frames shall be encapsulated and protected with the MGTK using the group cipher negotiated during the AMPE exchange.

For all other group addressed Management frames, the group addressed frame protection service shall take the following actions:

- Management frame protection for multicast/broadcast shall be set using the MLME-SETPROTECTION.request primitive with the Protectlist including a Key Type value of IGTK. A non-AP STA shall also set the Protect Type value to Rx. In an IBSS, a STA shall set the ProtectType value to Rx_Tx. An AP shall set the Protect Type value to Tx.
- The IGTK shall be installed using the MLME-SETKEYS.request primitive with the value IGTK for the Key Type subfield in the Key Information field in the IEEE 802.11 Key Descriptor.
- The frames shall be encapsulated and protected using BIP (see 12.5.4).

11.14 SA Query procedures

If dot11RSNAProtectedManagementFramesActivated is true, then the STA shall support the SA Query procedure.

To send an SA Query Request or SA Query Response frame to a peer STA, the SME shall issue an MLME-SA-QUERY.request or MLME-SA-QUERY.response primitive respectively. Reception of an SA Query Request or SA Query Response frame is signaled to the SME with an MLME-SA-QUERY.indication or MLME-SA-QUERY.confirm primitive respectively.

A STA that supports the SA Query procedure and receives an SA Query Request frame shall respond with an SA Query Response frame unless either of the following are true:

- the STA is not currently associated to the STA that sent the SA Query Request frame
- the STA has sent a (Re)Association Request frame within dot11AssociationResponseTimeOut but has not received a corresponding (Re)Association Response frame

NOTE—A non-AP and non-PCP STA does not respond if it is trying to reassociate with the AP or PCP that sent the SA Query Request frame (since, except in the case of FT to the same AP, it no longer has the PTKSA) or to another AP or PCP (it could maintain the old association and PTKSA until the reassociation is completed). There is no such restriction for an AP or PCP.

If a non-AP and non-PCP STA that has an SA with its AP or PCP for an association that negotiated management frame protection receives an unprotected Deauthentication or Disassociation frame with reason code INVALID_CLASS2_FRAME or INVALID_CLASS3_FRAME from the AP or PCP, the non-AP and non-PCP STA may use this as an indication that there might be a mismatch in the association state between itself and the AP or PCP. In such a case, the non-AP and non-PCP STA’s SME may initiate the SA Query procedure with the AP or PCP to verify the validity of the SA by issuing one MLME-SA-QUERY.request primitive every dot11AssociationSAQueryRetryTimeout TUs until a matching

MLME-SA-QUERY.confirm primitive is received or dot11AssociationSAQueryMaximumTimeout TUs from the beginning of the SA Query procedure has passed. If the AP or PCP responds to the SA Query request with a valid SA Query response, the non-AP STA should continue to use the SA. If no valid SA Query response is received, the non-AP and non-PCP STA's SME may delete the SA and temporal keys held for communication with the STA by issuing an MLME-DELETEKEYS.request primitive and the non-AP and non-PCP STA may move into State 1 (or State 2, for a DMG STA) with the AP.

11.15 HT BSS Operation

An HT STA that is creating or joining a BSS shall be able to receive and transmit at each of the MCS values listed in the Basic HT-MCS Set field of the HT Operation parameter of the MLME-START.request primitive or Basic HT-MCS Set field of the HT Operation parameter of the SelectedBSS parameter of the MLME-JOIN.request primitive.

A STA that transmits a frame that contains both an HT Operation element and a DSSS Parameter Set element shall set the Primary Channel field in the HT Operation element to the same value as the Current Channel field in the DSSS Parameter Set element.

11.16 20/40 MHz BSS operation

11.16.1 Rules for operation in 20/40 MHz BSS

The rules described in 11.16.1 through 11.16.12 are applicable to STAs that are either a STA 5G or a STA 2G4.

A 40MC STA shall support 20/40 BSS coexistence management.

NOTE—A 40MC HT STA that transmits a frame containing an Extended Capabilities element sets the 20/40 BSS Coexistence Management Support field of this element to 1.

An HT STA 2G4 that is a member of an IBSS and that transmits a frame containing an HT Operation element or Secondary Channel Offset element shall set the Secondary Channel Offset field of this element to SCN.

11.16.2 Basic 20/40 MHz BSS functionality

An HT AP declares its channel width capability (20 MHz only or 20/40 MHz) in the Supported Channel Width Set subfield of the HT Capabilities element.

An HT AP shall set the STA Channel Width field to 1 in frames in which it has set the Secondary Channel Offset field to SCA or SCB. An HT AP shall set the STA Channel Width field to 0 in frames in which it has set the Secondary Channel Offset field to SCN.

A non-AP HT STA declares its channel width capability (non-40MC HT STA or 40MC HT STA) in the Supported Channel Width Set subfield in the HT Capabilities element.

NOTE 1—A 20/40 MHz BSS might include any mixture of 40MC HT STAs, non-40MC HT STAs, and non-HT STAs. Protection requirements for mixed networks are defined in 10.26.

NOTE 2—A non-AP HT STA can switch between 40MC HT STA and non-40MC HT STA operation by disassociation followed by association.

An HT STA shall not indicate support for 40 MHz unless it supports reception and transmission of 40 MHz PPDUs using all MCSs within the Basic HT-MCS Set field of the HT Operation parameter of the MLME-START.request primitive or Basic HT-MCS Set field of the HT Operation parameter of the

SelectedBSS parameter of the MLME-JOIN.request primitive and all MCSs that are mandatory for the attached PHY.

An HT STA shall not transmit a 20 MHz PPDU containing one or more Data frames using the secondary channel of a 20/40 MHz BSSs. The Notify Channel Width frame may be used by a STA to notify another STA that the STA wishes to receive frames in the indicated channel width.

An HT STA that is a member of an IBSS adopts the value of the Secondary Channel Offset field in received frames according to the rules in 11.1.5 and shall not transmit either of the following:

- A value in the Secondary Channel Offset field that differs from the most recently adopted value
- An operating class in the Extended Channel Switch Announcement frame or element with a different behavior than the currently adopted PrimaryChannelLowerBehavior or PrimaryChannelUpperBehavior

11.16.3 Channel scanning and selection methods for 20/40 MHz operation

11.16.3.1 General

An HT STA shall set the following MIB attributes to true: dot11OperatingClassesImplemented, dot11OperatingClassesRequired, and dot11ExtendedChanneSwitchActivated.

An AP operating a 20/40 MHz BSS, on detecting an OBSS whose primary channel is the AP's secondary channel, switches to 20 MHz BSS operation and may subsequently move to a different channel or pair of channels. A DFS owner (DO) operating a 20/40 MHz IBSS, on detecting an OBSS whose primary channel is the DO's secondary channel, may choose to move to a different pair of channels.

NOTE—The setting up of a 40 MHz off-channel TDLS direct link is specified in 11.23.6.3.

11.16.3.2 Scanning requirements for a 20/40 MHz BSS

Before an AP or DO starts a 20/40 MHz BSS, it shall perform a minimum of dot11BSSWidthChannelTransitionDelayFactor OBSS scans (see 11.16.5) to search for existing BSSs.

If the AP or DO starts a 20/40 MHz BSS in the 5 GHz band and the BSS occupies the same two channels as any existing 20/40 MHz BSSs, then the AP or DO shall select a primary channel of the new BSS that is identical to the primary channel of the existing 20/40 MHz BSSs and a secondary channel of the new 20/40 MHz BSS that is identical to the secondary channel of the existing 20/40 MHz BSSs, unless the AP discovers that on these two channels are existing 20/40 MHz BSSs with different primary and secondary channels.

If an AP or DO starts a 20/40 MHz BSS in the 5 GHz band, the selected secondary channel should correspond to a channel on which no beacons are detected during the dot11BSSWidthChannelTransition-DelayFactor OBSS scan time performed by the AP or DO, unless there are beacons detected on both the selected primary and secondary channels.

NOTE—The 20/40 MHz channel sets and their corresponding behavior limits (i.e., choice of primary and secondary channels) permissible in each operating class are defined in Annex E and Annex D, respectively.

An HT AP or a DO that is also an HT STA should not start a 20 MHz BSS in the 5 GHz band on a channel that is the secondary channel of a 20/40 MHz BSS.

The AP or DO may continue to periodically scan after the BSS has been started. Information obtained during such scans is used as described within this subclause and within 11.16.2.

After starting a 20 MHz BSS, a 40MC HT AP 2G4 shall perform a minimum of dot11BSSWidthChannelTransitionDelayFactor OBSS scans, either by itself or through its associated STAs before making a transition from a 20 MHz BSS to a 20/40 MHz BSS. When the AP performs the scanning and the secondary channel for the 20/40 MHz BSS has been selected, then the scan shall be performed over the set of channels that are allowed operating channels within the current operational regulatory domain and whose center frequency falls within the *affected frequency range* given by Equation (11-1). When the AP performs the scanning without an intended secondary channel for the 20/40 MHz BSS or when the AP's associated STA(s) perform the scanning, then the scan shall be performed on all channels in the frequency band.

NOTE—A 40MC HT AP can change from operating a 20 MHz BSS to a 20/40 MHz BSS while maintaining associations by making a change to the transmitted value of the Secondary Channel Offset field.

$$\text{affected frequency range} = \left[\frac{f_P + f_S}{2} - 25 \text{ MHz}, \frac{f_P + f_S}{2} + 25 \text{ MHz} \right] \quad (11-1)$$

where

- f_P is the center frequency of channel P
- f_S is the center frequency of channel S

A 40MC HT AP 2G4 shall maintain a local boolean variable *20/40 Operation Permitted* that can have either the value true or false. The initial value of *20/40 Operation Permitted* shall be false. The value of *20/40 Operation Permitted* is recomputed according to Equation (11-2) whenever a BSS channel width trigger event is detected or whenever a period of time has elapsed with no BSS channel width triggers being detected and no overlap being reported, as defined in 11.16.12.

$$\begin{aligned} \text{20/40 Operation Permitted} = & (P == OP_i \text{ for all values of } i) \text{ AND} \\ & (P == OT_i \text{ for all values of } i) \text{ AND} \\ & (S == OS_i \text{ for all values of } i) \end{aligned} \quad (11-2)$$

where

- P is the operating or intended primary channel of the 20/40 MHz BSS
- S is the operating or intended secondary channel of the 20/40 MHz BSS
- OP_i is member i of the set of channels that are members of the channel set C and that are the primary operating channel of at least one 20/40 MHz BSS that was detected within the AP's BSA during the previous $\text{dot11BSSWidthChannelTransitionDelayFactor} \times \text{dot11BSSWidthTriggerScanInterval}$ seconds
- OS_i is member i of the set of channels that are members of the channel set C and that are the secondary operating channel of at least one 20/40 MHz BSS that was detected within the AP's BSA during the previous $\text{dot11BSSWidthChannelTransitionDelayFactor} \times \text{dot11BSSWidthTriggerScanInterval}$ seconds
- OT_i is member i of the set that comprises all channels that are members of the channel set C that were listed at least once in the Channel List fields of 20/40 BSS Intolerant Channel Report elements received during the previous $\text{dot11BSSWidthChannelTransitionDelayFactor} \times \text{dot11BSSWidthTriggerScanInterval}$ seconds and all channels that are members of the channel set C and that are the primary operating channel of at least one 20 MHz BSS that was detected within the AP's BSA during the previous $\text{dot11BSSWidthChannelTransitionDelayFactor} \times \text{dot11BSSWidthTriggerScanInterval}$ seconds
- C is the set of all channels that are allowed operating channels within the current operational regulatory domain and whose center frequency falls within the *affected frequency range* given by Equation (11-1)

If either side of “==” above is the empty set or has a null value, then the expression is defined to have a boolean value of true.

A 40MC HT AP 2G4 shall not start a 20/40 MHz BSS in the 2.4 GHz band if the value of the local variable *20/40 Operation Permitted* is false (see Equation (11-2)).

A 40MC HT AP 2G4 may transmit a frame containing a Secondary Channel Offset field set to a value of SCA or SCB only if *20/40 Operation Permitted* is true.

In addition to information obtained by the 40MC HT AP 2G4 through its own scanning, a 40MC HT AP 2G4 shall use 20/40 BSS Intolerant Channel Report element information from received 20/40 BSS Coexistence Management frames with a value of the Address 1 field that matches the 40MC HT AP 2G4 using either individual or group addressing, but with no qualification of the Address 3 value, when determining if *20/40 Operation Permitted* is true or false. The information from the Channel List fields of received 20/40 BSS Intolerant Channel Report elements is used in generating the *OT* set for Equation (11-2).

After initial establishment of the 20/40 MHz BSS, if the value of *20/40 Operation Permitted* becomes false, the 40MC HT AP 2G4 reverts to 20 MHz BSS operation (see 11.16.12). The 40MC HT AP 2G4 might subsequently move the BSS to a pair of channels where the value of *20/40 Operation Permitted* evaluates to true.

11.16.3.3 Channel management at the AP and in an IBSS

While operating a 20/40 MHz BSS, a DO or an AP may move its BSS, and an AP may switch the BSS to 20 MHz operation either alone or in combination with a channel move. These channel moving or BSS width switching operations might occur if, for example, another BSS starts to operate in either or both of the primary or secondary channels, or if radar is detected in either or both of the primary or secondary channels, or for other reasons that are beyond the scope of this standard. Specifically, the AP or DO may move its BSS to a different pair of channels, and the AP may separately, or in combination with the channel switch, change from a 20/40 MHz BSS to a 20 MHz BSS using either the primary channel of the previous channel pair or any other available 20 MHz channel. While operating a 20 MHz BSS, a DO or an AP may move its BSS, and an AP may switch the BSS to a 20/40 MHz BSS, either alone or in combination with a channel move.

When switching a 20/40 MHz BSS to 20 MHz BSS mode, the AP may recalculate the TS bandwidth budget and may delete one or more active TSs by invoking the MLME-DELTS.request primitive with a ReasonCode value of SERVICE_CHANGE_PRECLUDES_TS.

An AP switches between 20/40 MHz BSS and 20 MHz BSS as follows:

- By changing the value of the Secondary Channel Offset field of the HT Operation element in the Beacon frame, and/or
- By changing the value of the Secondary Channel Offset field of the Secondary Channel Offset element, and/or
- Through the New Operating Class field of transmitted Extended Channel Switch Announcement elements.

In order to maintain existing associations and/or minimize disruption to communications with other STAs while making a channel width change or while performing a channel pair relocation, an AP may inform HT STAs within its BSS that it is making the change by including an Extended Channel Switch Announcement element in Beacon, Probe Response, and Extended Channel Switch Announcement frame transmissions until the intended channel switch time. A DO may inform HT STAs within its BSS that it is performing a channel pair relocation by including an Extended Channel Switch Announcement element in Beacon, Probe Response, and Extended Channel Switch Announcement frame transmissions until the intended channel switch time. The New Channel Number field of the Extended Channel Switch Announcement element represents the new channel (when the BSS after relocation/width change will be a 20 MHz BSS) or the primary channel of the new pair of channels (when the BSS after relocation/width change will

be a 20/40 MHz BSS). When changing to a new pair of channels, the New Operating Class field specifies the position of the secondary channel relative to the new primary channel, i.e., either above or below.

When transmitting HT Operation elements, Channel Switch Announcement elements, and/or Extended Channel Switch Announcement elements, the AP moving the BSS or changing its channel width selects a combination of operating parameters from any single row of any one of the tables in Annex E that is appropriate for the current operating domain of the AP. Similarly, when transmitting HT Operation elements, Channel Switch Announcement elements, and/or Extended Channel Switch Announcement elements, the DO moving the BSS selects a combination of operating parameters from any single row of any one of the tables in Annex E that is appropriate for the current operating domain of the DO. The AP or DO selects one channel number from the “Channel set” column of the selected row. The AP or DO includes the selected information in subsequently transmitted frames that contain any combination of the following four elements:

- HT Operation element
- Channel Switch Announcement element
- Extended Channel Switch Announcement element
- Secondary Channel Offset element

The AP or DO shall set the Secondary Channel Offset field of transmitted HT Operation elements and transmitted Secondary Channel Offset elements to SCA if the Behavior limits set column of the selected row contains the value PrimaryChannelLowerBehavior. The AP or DO shall set the Secondary Channel Offset field of transmitted HT Operation elements and transmitted Secondary Channel Offset elements to SCB if the Behavior limits set column of the selected row contains the value PrimaryChannelUpperBehavior. The AP or DO shall set the Secondary Channel Offset field of transmitted HT Operation elements and transmitted Secondary Channel Offset elements to SCN if the Behavior limits set column of the selected row contains neither the value PrimaryChannelLowerBehavior nor the value PrimaryChannelUpperBehavior.

The AP or DO shall set the New Channel Number field of transmitted Channel Switch Announcement elements and Extended Channel Switch Announcement elements to the value of the selected channel from the selected row.

The AP or DO shall set the New Operating Class field of transmitted Extended Channel Switch Announcement elements to the value of the “Operating class” column of the selected row.

Movement of a 20/40 MHz BSS from one channel pair to a different channel pair and changing between 20 MHz and 20/40 MHz operation should be scheduled so that all STAs in the BSS, including STAs in power save mode, have the opportunity to receive at least one Extended Channel Switch Announcement element or Channel Switch Announcement element before the switch.

When the Extended Channel Switch Announcement element and Extended Channel Switch Announcement frame are transmitted in bands where dot11SpectrumManagementRequired is true, the Channel Switch Announcement element and Channel Switch Announcement frame may also be transmitted. A STA that announces a channel switch using both the Extended Channel Switch Announcement element and the Channel Switch Announcement element shall set the New Channel Number field of both elements to the same value. An HT STA that receives a channel switch announcement through both the Extended Channel Switch Announcement element and the Channel Switch Announcement element ignores the received Channel Switch Announcement element; this is called a *superseded* Channel Switch Announcement element.

For 20 MHz operation when the new operating class signifies 40 MHz channel spacing, the 20 MHz channel is the primary channel of the 40 MHz channel.

11.16.4 40 MHz PPDU transmission restrictions

11.16.4.1 Fields used to determine 40 MHz PPDU transmission restrictions

Several fields from various frames are used to convey information between STAs regarding the support for 40 MHz PPDU transmission and reception and regarding any current prohibition against the transmission and reception of 40 MHz PPDUs.

The rules defined in 11.16.4.2, 11.16.4.3, and 11.16.4.4 describe the behavior that accompanies those fields.

The fields that are used to determine the status of the transmission and reception of 40 MHz PPDUs are as follows:

- The Supported Channel Width Set subfield of the HT Capabilities element
- The Secondary Channel Offset field of the HT Operation element
- The STA Channel Width field of the HT Operation element
- The Channel Width field of the Notify Channel Width frame
- The Extended Channel Switch Announcement element

The Supported Channel Width Set subfield is used to indicate whether the transmitting STA is capable of transmitting and receiving 40 MHz PPDUs.

NOTE—The Supported Channel Width Set subfield transmitted by an AP is constant for the lifetime of its BSS as it is a parameter of the MLME-START.request primitive.

In addition to the restrictions on transmission of 40 MHz mask PPDUs found in 11.16.4.1 through 11.16.4.4, if a STA operating in the 2.4 GHz industrial, scientific, and medical (ISM) band has no means of determining the presence of non-IEEE-802.11 communication devices operating in the area, then the STA shall not transmit any 40 MHz mask PPDUs.

In addition to the restrictions on transmission of 40 MHz mask PPDUs found in 11.16.4.1 through 11.16.4.4, if a STA operating in the 2.4 GHz ISM band has a means of determining the presence of non-IEEE-802.11 communication devices operating in the area and determines either that no non-IEEE-802.11 communication device is operating in the area or that non-IEEE-802.11 communication devices are operating in the area but the STA implements a coexistence mechanism for these non-IEEE-802.11 communication devices, then the STA may transmit 40 MHz mask PPDUs; otherwise, the STA shall not transmit any 40 MHz mask PPDUs.

11.16.4.2 Infrastructure non-AP STA restrictions

A STA that is associated with an AP shall not transmit a value in the Supported Channel Width Set subfield that differs from a previously transmitted value during its current association.

The Secondary Channel Offset field is used to indicate whether the BSS is occupying a 40 MHz wide pair of channels and, when a secondary channel exists, whether it is above or below the primary channel in frequency. The Extended Channel Switch Announcement frame and the Extended Channel Switch Announcement element can each be used to indicate a transition from 20/40 MHz BSS operation to 20 MHz BSS operation and vice versa and to indicate whether a secondary channel, when it exists, is above or below the primary channel in frequency.

A 40MC HT STA shall maintain a local boolean variable *40MHzOperatingClass* as described here. The initial value of *40MHzOperatingClass* shall be false. The value of *40MHzOperatingClass* is recomputed according to the rules in this subclause at every TBTT and following the reception of a frame transmitted by the AP associated with the STA when that frame contains either of the following fields:

- Current Operating Class field
- New Operating Class field

The local boolean variable *40MHzOperatingClass* becomes true upon reception of a frame transmitted by the associated AP if the frame contained a Current Operating Class field with a value that corresponds to an operating class that corresponds to a channel spacing value of 40 MHz, as specified in Annex E.

The local boolean variable *40MHzOperatingClass* becomes false upon reception of a frame transmitted by the associated AP if the frame contained a Current Operating Class field with a value that corresponds to an operating class that does not correspond to a channel spacing value of 40 MHz.

The local boolean variable *40MHzOperatingClass* becomes true at the n^{th} TBTT following reception of a frame transmitted by the associated AP that contains an Extended Channel Switch Announcement element with a value of n in the Channel Switch Count field and a value in the New Operating Class field that corresponds to an operating class that corresponds to a channel spacing value of 40 MHz provided that the frame is the most recently received frame meeting the above conditions.

The local boolean variable *40MHzOperatingClass* becomes false at the n^{th} TBTT following reception of a frame transmitted by the associated AP that contains an Extended Channel Switch Announcement element with a value of n in the Channel Switch Count field and a value in the New Operating Class field that corresponds to an operating class that does not correspond to a channel spacing value of 40 MHz provided that the frame is the most recently received frame meeting the above conditions.

A STA can choose to dynamically constrain its operating channel width to 20 MHz while being a member of a 20/40 MHz BSS. Transitions to and from this constrained state are indicated using the transmission of a frame that carries the Channel Width field. A Channel Width field value of 0 indicates that the transmitting STA is not currently able to receive 40 MHz PPDUs, beginning at the end of the transmission of the frame that contained the Channel Width field.

A STA shall not transmit a frame containing a STA Channel Width field or a Channel Width field set to 1 if the value of its Supported Channel Width Set subfield is 0.

A STA that is associated with an infrastructure BSS (STA1) shall not transmit a 40 MHz PPDU containing one or more frames addressed to another STA (STA2) unless the following three conditions are true:

- The Supported Channel Width Set subfield of the HT Capabilities element of both STAs is equal to 1
- The Secondary Channel Offset field of the most recently received HT Operation element sent by the AP of the BSS has a value of SCA or SCB
- The local boolean variable *40MHzOperatingClass* is true.

If the above three conditions are met, STA1 should not transmit a 40 MHz PPDU containing one or more frames addressed to STA2 unless the following two conditions are true:

- Either STA1 has not received a Notify Channel Width frame that was transmitted by STA2, or the Channel Width field of the most recently received Notify Channel Width frame at STA1 that was transmitted by STA2 is nonzero.
- If STA2 is an AP, the STA Channel Width field of the most recently received HT Operation element that was transmitted by STA2 is equal to 1.

11.16.4.3 AP restrictions

An AP shall not transmit a 40 MHz PPDU containing one or more frames addressed to another STA unless the following three conditions are true:

- The Supported Channel Width Set subfield of the HT Capabilities element of the AP and all associated STAs are equal to a nonzero value.
- The Secondary Channel Offset field of the AP's most recently transmitted HT Operation element has a value of SCA or SCB
- The local boolean variable *40MHzOperatingClass* is true.

If the above three conditions are met, the AP should not transmit a 40 MHz PPDU containing frames addressed to another STA unless either the AP has not received a Notify Channel Width frame that was transmitted by the STA or the Channel Width field of the most recently received Notify Channel Width frame at the AP that was transmitted by the STA is nonzero.

An AP shall not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless the following three conditions are true:

- The Supported Channel Width Set subfield of the HT Capabilities element of the AP is equal to 1
- The Secondary Channel Offset field of the AP's most recently transmitted HT Operation element has a value of SCA or SCB
- The local boolean variable *40MHzOperatingClass* is true.

If the above three conditions are met, the AP should not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless either the AP has not received a Notify Channel Width frame from any STA in the BSS or the Channel Width field of the most recently received Notify Channel Width frame from each STA that transmitted a Notify Channel Width frame is nonzero.

11.16.4.4 Restrictions on non-AP STAs that are not infrastructure BSS members

An HT STA 2G4 that is not a member of an infrastructure BSS shall not transmit a 40 MHz mask PPDU.

An HT STA 5G that is not associated with an infrastructure BSS (STA1) shall not transmit a 40 MHz PPDU containing frames addressed to another STA (STA2) unless the following three conditions are true:

- The Supported Channel Width Set subfield of the HT Capabilities element of both STAs is equal to 1
- The Secondary Channel Offset field of the most recently received HT Operation element sent by STA2 has a value of SCA or SCB
- The Secondary Channel Offset field of the most recently transmitted HT Operation element sent by STA1 has a value of SCA or SCB

If the above three conditions are met, STA1 should not transmit a 40 MHz PPDU containing one or more frames addressed to STA2 unless STA1 has not received a STA Channel Width field that was transmitted by STA2 or the value of the most recently received STA Channel Width field at STA1 that was transmitted by STA2 is nonzero.

An HT STA 5G that is not associated with an infrastructure BSS (STA1) shall not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless the following two conditions are true:

- The Supported Channel Width Set subfield of the HT Capabilities element transmitted by STA1 is equal to 1.
- The Secondary Channel Offset field of the HT Operation element most recently transmitted by STA1 has a value of SCA or SCB.

If the above two conditions are met, STA1 should not transmit a 40 MHz PPDU containing one or more frames with a group address in the Address 1 field unless the most recently received STA Channel Width field for each other known member of the BSS of which STA1 is a member is equal to 1.

11.16.5 Scanning requirements for 40-MHz-capable STA

An OBSS scan operation is a passive or active scan of a set of channels that are potentially affected by 20/40 MHz BSS operation, i.e., the 20 MHz channels that wholly or partly overlap the 40 MHz signal. Each channel in the set may be scanned more than once during a single OBSS scan operation. OBSS scans are performed by STAs that are 40MC HT STA 2G4. STAs that are 40MC HT STA 5G are not required to perform OBSS scan operations.

NOTE—STAs that perform OBSS scans report discovered BSSs and received 20/40 BSS coexistence information to their associated AP (see 11.16.12).

During an individual scan within an OBSS scan operation, the minimum per-channel scan duration is `dot11OBSSScanPassiveDwell TU` (when scanning passively) or `dot11OBSSScanActiveDwell TU` (when scanning actively). During an OBSS scan operation, each channel in the set is scanned at least once per `dot11BSSWidthTriggerScanInterval seconds`, and the minimum total scan time (i.e., the sum of the scan durations) per channel within a single OBSS scan operation is `dot11OBSSScanPassiveTotalPerChannel TU` for a passive scan and `dot11OBSSScanActiveTotalPerChannel TU` for an active scan.

NOTE—The values provided in the previous paragraph indicate the minimum requirements. For some combinations of parameter values, it is necessary to exceed the minimum values of some parameters in order to meet the minimum value constraints of all parameters.

When an AP transmits an Overlapping BSS Scan Parameters element, the value of each of the fields of the element shall be set to the value of the MIB attribute from the transmitting AP's MIB according to the mapping between the frame fields and MIB attributes as defined in 9.4.2.59.

Upon receipt of a frame containing an Overlapping BSS Scan Parameters element from the AP with which a 40MC HT STA 2G4 is associated, the MLME of the receiving 40MC HT STA 2G4 shall update each of the values of the MIB attributes used during OBSS scanning operations according to the mapping between the frame fields and MIB attributes as defined in 9.4.2.59.

A 40MC HT AP 2G4 may transmit frames containing an Overlapping BSS Scan Parameters element to any or all associated STAs in order to provide OBSS scan parameter values that are different from the default values.

A 40MC HT STA 2G4 that is associated with a 40MC HT AP 2G4 shall perform at least one OBSS scan every `dot11BSSWidthTriggerScanInterval seconds`, unless the 40MC HT STA 2G4 satisfies the conditions described in 11.16.6.

11.16.6 Exemption from OBSS scanning

A 40MC HT STA 2G4 shall maintain a local variable *ActivityFraction*. The value of *ActivityFraction* is defined by Equation (11-3).

$$ActivityFraction = \frac{T_{ACTIVE}}{T_{MEASURE-ACTIVE}} \quad (11-3)$$

where

T_{ACTIVE} is the total duration of transmitted MSDUs and received individually addressed MSDUs during the previous $T_{MEASURE-ACTIVE}$ seconds

$T_{MEASURE-ACTIVE}$ is $\text{dot11BSSWidthChannelTransitionDelayFactor} \times \text{dot11BSSWidthTriggerScan-Interval}$ seconds.

A 40MC HT STA 2G4 may transmit to its associated AP a 20/40 BSS Coexistence Management frame with the Scanning Exemption Request field in the 20/40 Coexistence element set to 1.

If the last 20/40 BSS Coexistence Management frame received by a 40MC HT STA 2G4 in an individually addressed frame from its associated AP has the Scanning Exemption Grant field equal to 1, the STA is exempted from scanning whenever the value of its local variable *ActivityFraction* is less than $\text{dot11OBSSScanActivityThreshold}/10\,000$.

A 40MC HT AP 2G4 shall not transmit a 20/40 BSS Coexistence Management frame with the Scanning Exemption Grant field set to 1 addressed to a 40MC HT STA if the following condition is true:

- The 40MC HT STA has transmitted one or more channel report elements and is the only STA in the BSS that has indicated one or more channels on which a STA has found conditions that disallow the use of a 20/40 MHz BSS.

If there is more than one 40MC HT STA in the BSS that has indicated conditions that disallow the use of 20/40 MHz BSS on a specific channel, then the following apply:

- If all of the 40MC HT STAs that have indicated unavailability of a channel have also requested to be exempt from scanning, the AP shall disallow at least one of the 40MC HT STA to be exempt from scanning.
- If, from the group of 40MC HT STAs that have indicated unavailability of a channel, there is at least one 40MC HT STA that has not requested to be exempt from scanning, the AP may allow all of the STAs that have requested to be exempt from scanning to be exempted from scanning.

11.16.7 Communicating 20/40 BSS coexistence information

In addition to the 20/40 BSS Coexistence Management frame, a STA can include the 20/40 BSS Coexistence element in transmitted Beacon, Probe Request, Probe Response, (Re)Association Request, and (Re)Association Response frames.

11.16.8 Support of DSSS/CCK in 40 MHz

Transmission and reception of PPDU using DSSS/CCK by 40MC HT STAs is managed using the DSSS/CCK Mode in 40 MHz subfield of the HT Capability Information field in the HT Capabilities element (see 9.4.2.56.2).

An HT STA declares its capability to use DSSS/CCK rates while it has a 40 MHz operating channel width through the DSSS/CCK Mode in 40 MHz subfield of its (Re)Association Request frames.

If the DSSS/CCK Mode in 40 MHz subfield is equal to 1 in Beacon and Probe Response frames, an associated HT STA in a 20/40 MHz BSS may generate DSSS/CCK transmissions. If the subfield is equal to 0, then the following apply:

- An associated HT STA shall not generate DSSS/CCK transmissions.
- The AP shall not include an ERP element in its Beacon and Probe Response frames.
- The AP shall not include DSSS/CCK rates in the Supported Rates and BSS Membership Selectors element.
- The AP shall refuse association requests from a STA that includes only DSSS/CCK rates in its Supported Rates and BSS Membership Selectors element and Extended Supported Rates and BSS Membership Selectors element.

A STA not operating in the 2.4 GHz band shall set the DSSS/CCK Mode in 40 MHz subfield to 0.

11.16.9 STA CCA sensing in a 20/40 MHz BSS

This subclause defines CCA sensing rules for an HT STA that is not a VHT STA. For rules related to a VHT STA, see 10.3.2.6, 10.22.2.6, and 10.22.3.

A STA may transmit a 20 MHz mask PPDU in the primary channel following the rules in 10.22.2.

A STA transmitting a 40 MHz mask PPDU that begins a TXOP using EDCA as described in 10.22.2.4 or that is using a PIFS as permitted in 10.3.2.3.4 shall sense CCA on both the 20 MHz primary channel and the 20 MHz secondary channel before the 40 MHz mask PPDU transmission starts.

Unless explicitly stated otherwise, a STA may treat a PHY-CCA.indication(BUSY) primitive as a PHY-CCA.indication(IDLE) primitive in the following cases:

- If the channel-list parameter is present and equal to {secondary} and the STA is transmitting a 20 MHz mask PPDU on the primary channel, or
- If the channel-list parameter is present and equal to {primary} and the STA is transmitting a 20 MHz mask PPDU on the secondary channel.

NOTE—Transmission of PPDUs on the secondary channel is also subject to constraints in 11.16.2.

At the specific slot boundaries (see Figure 10-26) determined by the STA based on the 20 MHz primary channel CCA, when the transmission begins a TXOP using EDCA (as described in 10.22.2.4), the STA may transmit a pending 40 MHz mask PPDU only if the secondary channel has also been idle during the times the primary channel CCA is performed (defined in 10.22.2.4) during an interval of a PIFS for the 5 GHz band and DIFS for the 2.4 GHz band immediately preceding the expiration of the backoff counter. If a STA was unable to transmit a 40 MHz mask PPDU because the secondary channel was occupied during this interval, it may take one of the following steps:

- a) Transmit a 20 MHz mask PPDU on the primary channel.
- b) Restart the channel access attempt. In this case, the STA shall invoke the backoff procedure as specified in 10.22.2 as though the medium is busy as indicated by either physical or virtual CS and the backoff timer has a value of 0.

NOTE—As a result of this rule, the STA selects a new random number using the current value of CW[AC], and the retry counters are not updated.

When a TXOP is obtained for a 40 MHz PPDU, the STA may transmit 40 MHz PPDUs and/or 20 MHz PPDUs during the TXOP. When the TXOP is obtained by the exchange of 20 MHz PPDUs only in the primary channel, the STA shall not transmit 40 MHz PPDUs during the TXOP.

11.16.10 NAV assertion in 20/40 MHz BSS

An HT STA shall update its NAV using the Duration/ID field value in any frame received in a 20 MHz PPDU in the primary channel or received in a 40 MHz PPDU and that does not have an RA matching the STA's MAC address.

NOTE—A STA need not set its NAV in response to 20 MHz frames received on the secondary channel or any other channel that is not the primary channel, even if it is capable of receiving those frames.

11.16.11 Signaling 40 MHz intolerance

An HT STA 2G4 shall set the Forty MHz Intolerant field to 1 in transmitted HT Capabilities elements if dot11FortyMHzIntolerant is true; otherwise, the field shall be set to 0.

A STA 2G4 shall set the Forty MHz Intolerant field to 1 in transmitted 20/40 BSS Coexistence fields if dot11FortyMHzIntolerant is true; otherwise, the field shall be set to 0. A STA 2G4 that is not an HT STA 2G4 shall include a 20/40 BSS Coexistence element in Management frames in which the element may be present if dot11FortyMHzIntolerant is present and dot11FortyMHzIntolerant is true.

A STA 5G shall set the Forty MHz Intolerant field to 0 in transmitted HT Capabilities elements and 20/40 BSS Coexistence fields.

11.16.12 Switching between 40 MHz and 20 MHz

A VHT STA is not required to perform any of the behavior described in this subclause associated with Information Request and 20 MHz BSS Width Request.

The following events are defined to be BSS channel width trigger events (TEs):

- **TE-A:** On any of the channels of the channel set defined in Clause 18, reception of a Beacon frame that does not contain an HT Capabilities element.
- **TE-B:** On any of the channels of the channel set defined in Clause 18, reception of a 20/40 BSS Coexistence Management, Beacon, Probe Request, or Probe Response frame that contains a value of 1 in a Forty MHz Intolerant field and that has the Address 1 field equal to the receiving STA's address or to a group address value, with no further addressing qualifications.
- **TE-C:** Reception of a 20/40 BSS Coexistence Management frame with the 20 MHz BSS Width Request field equal to 1 and with a value of the Address 1 field that matches the receiving STA using either individual or group addressing and with a value of the TA field that corresponds to the MAC address of a STA with which the receiver is associated.
- **TE-D:** Reception of a 20/40 BSS Coexistence Management frame containing at least one 20/40 BSS Intolerant Channel Report element with a nonzero length and with a value of the Address 1 field equal to the receiving STA's address or to a group address value, but with no qualification of the Address 3 value.

A 40MC HT AP 2G4 shall reevaluate the value of the local variable *20/40 Operation Permitted* (see 11.16.3.2) when either of the following events occurs:

- A BSS channel width trigger event TE-A is detected.
- A BSS channel width trigger event TE-D is detected.

A 40MC HT AP 2G4 may reevaluate the value of the local variable *20/40 Operation Permitted* (see 11.16.3.2) when either of the following situations occurs:

- No BSS channel width trigger events TE-A are detected for a period of time equal to dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds.
- No BSS channel width trigger events TE-D are detected for a period of time equal to dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds.

A 40MC HT AP 2G4 that detects either BSS channel width trigger event TE-B or TE-C or that determines that the value of its variable *20/40 Operation Permitted* has changed from true to false shall set the Secondary Channel Offset field to SCN in transmitted HT Operation elements beginning at the next DTIM or next TBTT if no DTIMs are transmitted to indicate that no secondary channel is present (i.e., that the BSS operating width is 20 MHz).

A 40MC HT AP 2G4 shall not set the Secondary Channel Offset field to a value of SCA or SCB in transmitted HT Operation elements unless the following two conditions have been met:

- A period of dot11BSSWidthChannelTransitionDelayFactor × dot11BSSWidthTriggerScanInterval seconds have elapsed during which no BSS channel width trigger events TE-B or TE-C are detected.
- The value of the local variable *20/40 Operation Permitted* (see 11.16.3.2) is true.

To request an update of the status of the 20 MHz BSS Width Request field, a 40MC HT AP 2G4 can transmit a 20/40 BSS Coexistence Management frame with a value of 1 in the Information Request field as described in 11.18.

A 40MC HT STA 2G4 that is associated with a 40MC HT AP 2G4 shall maintain a record of detected BSS channel width trigger events as follows:

- For each detected BSS channel width trigger event TE-A:
 - If a DSSS Parameter Set field is present in the received Beacon frame, the channel of the BSS channel width trigger event is the value of the Current Channel field of the DSSS Parameter Set field; otherwise, the channel of the BSS channel width trigger event is the channel on which the detecting STA received the Beacon frame.
 - If a Supported Operating Classes element is present in the received Beacon frame, the operating class of the BSS channel width trigger event is the value of the Current Operating Class field of the Supported Operating Classes element of the received Beacon frame; otherwise, the operating class of the BSS channel width trigger event is “unknown.”
- For each detected BSS channel width trigger event TE-A of a unique combination of operating class and channel, the 40MC HT STA 2G4 shall maintain a record containing two variables:
 - The operating class of the BSS channel width trigger event
 - The channel of the BSS channel width trigger event

NOTE—If a BSS channel width trigger event TE-A is detected for an operating class and channel combination for which no record exists, the STA creates such a record.

If a BSS channel width trigger event TE-A is detected for an operating class and channel combination for which a record already exists, the information in that record shall be updated with the information determined from the new trigger event.

For all BSS channel width trigger events TE-B, the 40MC HT STA 2G4 shall maintain a single record containing an indication of whether one or more trigger events TE-B have been detected.

At the completion of an OBSS scan operation (i.e., at the end of the period of time equal to dot11BSSWidthTriggerScanInterval) or when it receives a 20/40 BSS Coexistence Management frame from its associated AP that contains a value of 1 in the Information Request field, a 40MC HT STA 2G4 that is associated with a 40MC HT AP 2G4 shall create a 20/40 BSS Coexistence Management frame by including a value of 0 for all fields of a 20/40 BSS Coexistence Management frame and then transferring information from the BSS channel width trigger event TE-A and TE-B records to the frame according to the following four steps:

- For each unique operating class that is stored in the set of BSS channel width trigger event TE-A records, the STA shall create a 20/40 BSS Intolerant Channel Report element for inclusion in the frame and include all of the unique channels associated with the operating class in the channel list of that element.
- The STA sets the Forty MHz Intolerant field of the 20/40 BSS Coexistence element based on A STA’s FortyMHzIntolerant (see 11.16.11).
- The STA shall set to 1 the 20 MHz BSS Width Request field of the 20/40 BSS Coexistence element for inclusion in the frame if a record for BSS channel width trigger event TE-B exists and indicates that at least one trigger event TE-B has been detected.
- The STA may set to 1 the Information Request field.

Upon completion of these four steps, the 40MC HT STA 2G4 shall delete all records for trigger events TE-A and TE-B. Subsequently detected trigger events cause the creation of new records as necessary to be used in subsequently generated 20/40 BSS Coexistence Management frames. Following the record deletion, the

40MC HT STA 2G4 shall transmit to its associated 40MC HT AP 2G4 the 20/40 BSS Coexistence Management frame if any of the following conditions is true:

- At least one 20/40 BSS Intolerant Channel Report element with the Length field equal to a nonzero value is included.
- The Forty MHz Intolerant field is equal to 1.
- The 20 MHz BSS Width Request field is equal to 1.
- The Information Request field is equal to 1.
- The frame was created in response to the reception of an Information Request field that was equal to 1.

11.17 Phased coexistence operation (PCO)

11.17.1 General description of PCO

The PCO mechanism is obsolete. Consequently, this subclause might be removed in a later revision of this standard.

PCO is an optional coexistence mechanism in which a PCO active AP divides time into alternating 20 MHz and 40 MHz phases (see Figure 11-30). The PCO active AP reserves the 20 MHz primary channel and the 20 MHz secondary channel in turn to start the 40 MHz phase and resets the NAV in the 20 MHz channels in the opposite order to start the 20 MHz phase. Due to the protection of the 40 MHz period in both channels, it is tolerant of OBSSs on both 20 MHz halves of a 40 MHz channel.

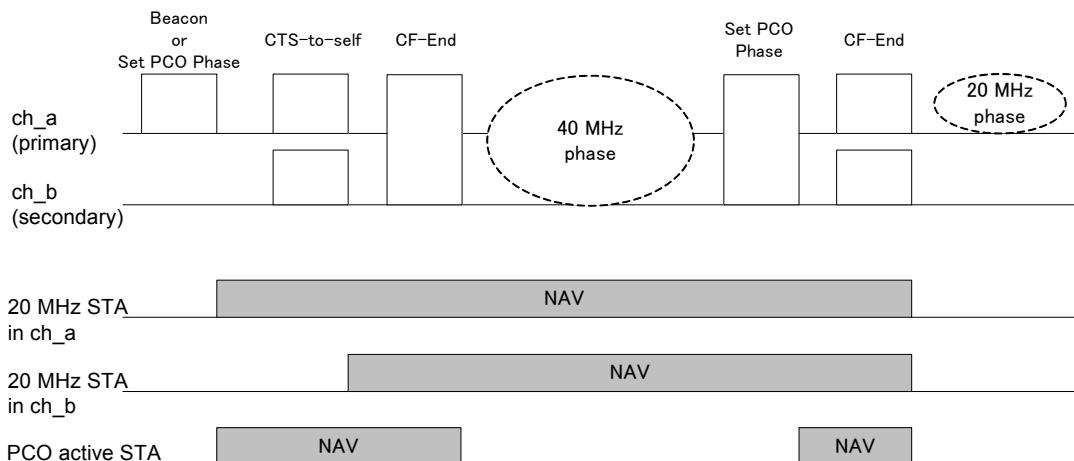

Figure 11-30—Phased coexistence operation (PCO)

A PCO active STA that does not know the current PCO phase shall transmit using a 20 MHz PPDU.

During the 40 MHz phase, a PCO active STA shall transmit Data frames using a 40 MHz HT PPDU and Control frames using a non-HT duplicate or a 40 MHz HT PPDU, with the following exceptions:

- Any CF-End frame shall be sent using only a 40 MHz HT PPDU.
- A PCO active AP may transmit 20 MHz group addressed frames as defined in 10.7.5.3.

A PCO active STA shall transmit Management frames in 20 MHz or 40 MHz PPDUs according to 10.7.5 during the 40 MHz phase, except that Set PCO Phase frames shall be sent following the rules specified in 11.17.2.

During the 40 MHz phase, a PCO active STA may act as though the HT Protection field were equal to no protection mode, as defined in 10.26.3.1.

During the 20 MHz phase, a PCO active STA shall not transmit frames using a 40 MHz (HT or non-HT duplicate) PPDU. The protection of a PCO active STA during the 20 MHz phase is the same as protection in a 20 MHz BSS.

During the 20 MHz phase, a STA may transmit a 40 MHz mask PPDU that is not also a 40 MHz PPDU.

NOTE—This rule allows a STA to transmit 20 MHz PPDUs without requiring it to change to a 20 MHz transmit mask.

A PCO-capable AP may set the PCO Active field to 1 only if it is in a 20/40 MHz BSS.

NOTE—A non-PCO-capable 20/40 STA regards the PCO active BSS as a PCO inactive BSS. A non-PCO-capable 20/40 STA that associates with a PCO active BSS protects its transmissions as though the BSS were a PCO inactive BSS.

The value indicated by the PCO Transition Time field in the HT Extended Capabilities field is measured from the end of the PPDU carrying the Set PCO Phase frame. The PCO active STA shall be able to receive a PPDU using the new channel width no later than the value specified by the PCO Transition Time field after the end of the PPDU carrying the Set PCO Phase frame.

A VHT STA shall not transmit VHT PPDUs during a PCO 40 MHz phase.

11.17.2 Operation at a PCO active AP

A PCO-capable AP activates PCO if it decides that PCO active BSS is more appropriate than either PCO inactive BSS or 20 MHz BSS in the current circumstances. The algorithm for making this decision is beyond the scope of this standard.⁴⁵

A PCO active AP shall set the PCO Active field in the HT Operation element to 1.

When a PCO active AP detects that PCO is not providing a performance benefit, the PCO active AP may deactivate PCO and operate in either a PCO inactive BSS or 20 MHz BSS. A PCO-capable AP shall set the PCO Active field in the HT Operation element to 0 when PCO operation is disabled. Since the AP advertises the current mode in its Beacon and Probe Response frames, its associated STAs are informed of the mode change.

Values of the PCO Transition Time field in the HT Extended Capabilities field from 1 to 3 indicate the maximum time the PCO active STA takes to switch between a 20 MHz channel width and a 40 MHz channel width. A PCO active AP may set the PCO Transition Time field to 0 when it requires the associated PCO active STAs to be able to receive 40 MHz frames and respond with 40 MHz frames during the 20 MHz phase.

The PCO active AP shall increase the value of the PCO Transition Time field if the PCO active AP accepts the association of a PCO-capable STA whose value of the PCO Transition Time field exceeds the one currently used by the PCO active AP. If the PCO active AP decides not to extend its transition time to meet the value of the requesting STA, the PCO active AP shall deny the association. The AP may choose to continue PCO when a non-PCO-capable 20/40 STA requests association, and in such cases, the PCO active AP shall be able to receive 40 MHz frames and respond using 40 MHz frames during the 20 MHz phase.

⁴⁵A PCO-capable AP might consider the performance impact, e.g., throughput and jitter, caused by and given to STAs based on their capabilities, traffic types, or load to determine the BSS's PCO mode. STAs under consideration might be not only associated STAs but also those that were detected in OBSSs.

A PCO active AP that indicates a switch to the 40 MHz phase by a PCO Phase field in a Beacon frame or by a PCO Phase Control field in a Set PCO Phase frame and that transmits a nonzero value of the PCO Transition Time field shall wait for at least the transition time specified by the PCO Transition Time field before sending a CF-End frame in the 40 MHz channel to start the 40 MHz operating phase.

When switching to the 40 MHz phase, a PCO active AP indicates a NAV duration either in the CF Parameter Set element of a Beacon frame or in the Duration/ID field of a Set PCO Phase frame sent on the primary channel that shall protect up to the end of the intended 40 MHz phase plus a transition time. A PCO active AP may continue the CFP after the 40 MHz phase by setting a longer duration for the CFP. The value of the Duration/ID field in a CTS-to-self frame sent to protect a 40 MHz phase shall be set to protect up to the intended end of the 40 MHz phase plus a transition time. The CTS-to-self frame shall be sent in a non-HT duplicate PPDU. The transmission of the CTS-to-self frame shall be delayed until the secondary channel CCA has indicated idle for at least a PIFS. It need not sense the primary channel because it is already reserved by a Beacon frame or a Set PCO Phase frame.

If the PCO Transition Time field is nonzero, a PCO active AP shall start a timer with a timeout value equal to the time specified by the PCO Transition Time field after transmitting a Beacon frame or a Set PCO Phase frame. If this timer expires while attempting to reserve the secondary channel, the AP shall transmit a Set PCO Phase frame indicating a switch back to the 20 MHz phase and shall transmit a CF-End frame on the primary channel.

NOTE—If this timer expires while attempting to reserve the secondary channel, the AP abandons switching to the 40 MHz phase to avoid an unexpectedly long delay.

A PCO active AP may transmit a Set PCO Phase frame in a non-HT duplicate PPDU followed by a CF-End frame in a 40 MHz HT PPDU to reserve both the primary and secondary channels again for the 40 MHz phase or to extend the 40 MHz phase. The value of the Duration/ID field in a Set PCO Phase frame contained in a non-HT duplicate PPDU for this intent shall protect up to the end of the intended 40 MHz phase plus the transition time.

To start the 20 MHz phase, a PCO active AP shall send a Set PCO Phase frame in a 40 MHz HT PPDU or in a non-HT duplicate PPDU with the Duration/ID field set to cover the transition time. It may also send a CF-End frame in both primary and secondary channels following the Set PCO Phase frame, where a CF-End frame in the primary channel shall be sent out at least after the transition time. The Duration/ID field of the Set PCO Phase frame for this case shall cover the transition time plus the duration of a CF-End frame.

A PCO active AP may broadcast a Set PCO Phase frame to advertise the current PCO phase to PCO active STAs.

Although PCO improves throughput in some circumstances, PCO might also introduce jitter. To minimize the jitter, the maximum duration of 40 MHz phase and 20 MHz phase is dot11PCOFortyMaxDuration and dot11PCOTwentyMaxDuration, respectively. Also in order for the PCO active AP to give opportunities for each STA to send frames, the minimum duration of 40 MHz phase and 20 MHz phase is dot11PCOFortyMinDuration and dot11PCOTwentyMinDuration, respectively.

11.17.3 Operation at a PCO active non-AP STA

If the PCO field in the Association Request frame to a PCO active AP is equal to 1 and the association succeeds, the STA shall operate in PCO mode. When requesting association, a PCO-capable STA shall set the PCO Transition Time field to 0 if the PCO active AP has set the PCO Transition Time field to 0. A PCO-capable STA may attempt to associate with a transition time that is larger than one currently advertised by the PCO active AP. If such an association fails, the PCO-capable non-AP STA may regard the BSS as a PCO inactive BSS and may attempt an association as a non-PCO-capable 20/40 STA.

NOTE—A STA that does not support the PCO transition time indicated by an AP might still attempt association with that AP. The AP will either refuse the association based on PCO transition time or respond by adjusting its PCO transition time to suit the STA.

A PCO active non-AP STA may transmit a Probe Request frame to the associated PCO active AP to determine the current PCO phase. A PCO active STA associated with a PCO active AP shall switch its operating phase from 20 MHz channel width to 40 MHz channel width when it receives from its AP a Beacon frame or a Probe Response frame that contains the PCO Phase field equal to 1 or a Set PCO Phase frame with the PCO Phase Control field equal to 1. The value of the CFP DurRemaining field in the CF Parameter Set element of a Beacon frame or the value of the Duration/ID field of a Set PCO Phase frame shall be interpreted as the duration of the PCO 40 MHz phase.

A PCO active STA associated with a PCO active AP shall switch its operating phase from 40 MHz channel width to 20 MHz channel width when it receives a Beacon frame or a Probe Response frame that contains the PCO Phase field equal to 0 or a Set PCO Phase frame with the PCO Phase Control field equal to 0. It also may switch from 40 MHz channel width to 20 MHz channel width based on the expiration of the value in the Duration/ID field of a Set PCO Phase frame that indicated a 40 MHz phase or based on the expiration of the value in the CFP DurRemaining field of the CF Parameter Set element of a Beacon frame that indicated a 40 MHz phase.

A PCO active STA shall halt PCO operation if it receives an HT Operation element from its AP with the PCO Active field equal to 0.

NOTE—An HT STA might change its PCO capabilities by disassociating followed by associating with an AP.

11.18 20/40 BSS Coexistence Management frame usage

A STA that supports the 20/40 BSS Coexistence Management frame type shall set the 20/40 BSS Coexistence Management Support field to 1 in transmitted Extended Capabilities elements.

A STA that supports the 20/40 BSS Coexistence Management frame type shall include an Extended Capabilities element in transmitted Beacon, (Re)Association Request, (Re)Association Response, Probe Request, and Probe Response frames.

A STA shall not transmit to another STA a 20/40 BSS Coexistence Management frame with an individual address in the Address 1 field if the Extended Capabilities element from the recipient STA contained a value of 0 in the 20/40 BSS Coexistence Management Support field. A STA that transmits a 20/40 BSS Coexistence Management frame may set the Address 1 field to a group address.

NOTE—A 20/40 BSS Coexistence Management frame is a Class 1 frame and, therefore, can be sent to a STA that supports reception of such frames and that is not a member of the same BSS as the transmitting STA. In such a case, the BSSID of the frame is set to the wildcard BSSID value, regardless of whether the Address 1 field contains an individual or group address value.

A STA may transmit a 20/40 BSS Coexistence Management frame that contains a value of 1 for the Request Information field to another STA that supports the transmission of and reception of the 20/40 BSS Coexistence Management frame, except when the frame is a response to a 20/40 BSS Coexistence Management frame that contains a value of 1 for the Request Information field.

A non-VHT STA that receives a 20/40 BSS Coexistence element with the Information Request field equal to 1, a value of the Address 1 field that matches the receiving STA using an individual address, and a nonwildcard BSSID field that matches the STA's BSS shall immediately queue for transmission a 20/40 BSS Coexistence Management frame with the transmitting STA as the recipient.

11.19 RSNA A-MSDU procedures

When `dot11RSNAActivated` is true, a STA indicates support for payload protected A-MSDUs (PP A-MSDUs) or signaling and payload protected A-MSDUs (SPP A-MSDUs) during (re)association. On either (re)association, the associating STA and its peer STA both determine and maintain a record of whether an encrypted A-MSDU sent to its peer is to be a PP A-MSDU or an SPP A-MSDU based on the value of the SPP A-MSDU Capable and SPP A-MSDU Required subfields of the RSN Capabilities field of the RSNE (see 9.4.2.25.4).

Table 11-12 defines behavior related to the transmission and reception of individually addressed A-MSDUs of a first HT STA (STA1) that has successfully negotiated an RSNA (re)association with a second HT STA (STA2). Reception and transmission of A-MSDUs using a non-RSN association is unaffected by the values of the SPP A-MSDU Capable and SPP A-MSDU Required subfields.

Table 11-12—A-MSDU STA behavior for RSN associations

| STA1 state | | STA2 state | | STA1 action with respect to STA2 |
|--------------------|---------------------|--------------------|---------------------|---|
| SPP A-MSDU capable | SPP A-MSDU required | SPP A-MSDU capable | SPP A-MSDU required | |
| 0 | 0 | X | 0 | May transmit PP A-MSDU. Shall not transmit SPP A-MSDU. Shall receive PP A-MSDU. Received SPP A-MSDU MIC fails. |
| 0 | 0 | X | 1 | Shall not transmit PP A-MSDU. Shall not transmit SPP A-MSDU. Shall discard received (PP and SPP) A-MSDU. |
| 0 | 1 | X | X | Shall not transmit PP A-MSDU. Shall not transmit SPP A-MSDU. Shall discard received (PP and SPP) A-MSDU. |
| 1 | 0 | 0 | 0 | May transmit PP A-MSDU. Shall not transmit SPP A-MSDU. Shall receive PP A-MSDU. Received SPP A-MSDU MIC fails. |
| 1 | 0 | 0 | 1 | Shall not transmit PP A-MSDU. Shall not transmit SPP A-MSDU. Shall discard received (PP and SPP) A-MSDU. |
| 1 | X | 1 | X | Shall not transmit PP A-MSDU. May transmit SPP A-MSDU. Received PP A-MSDU MIC fails. Shall receive SPP A-MSDU. |
| 1 | 1 | 0 | X | Shall not transmit PP A-MSDU. Shall not transmit SPP A-MSDU. Shall discard received (PP and SPP) A-MSDU. |

NOTE—X = Not significant.

An AP may transmit an SPP A-MSDU for a GCR group address if it has successfully negotiated RSNA (re)associations with all associated STAs that have an active GCR agreement for this group address.

11.20 Public Action frame addressing

A STA that is a member of a BSS and that transmits an individually addressed Public Action frame to a STA that is not a member of the same BSS shall set the BSSID field of the frame as follows:

- If the recipient STA is known to be a member of another BSS (including being an AP) and that BSS's BSSID is known, the BSSID field shall be set to the BSS's BSSID or the wildcard BSSID value.
- Otherwise, the BSSID field of the frame shall be set to the wildcard BSSID value.

A STA that is a member of a BSS and that transmits a group addressed Public Action frame shall set the BSSID field of the frame to the BSS's BSSID or the wildcard BSSID value.

A STA that is a member of a BSS and that transmits an individually addressed Public Action frame to a STA that is a member of the same BSS shall set the BSSID field of the frame to the BSS's BSSID.

A STA that is not a member of a BSS and that transmits a Public Action frame shall set the BSSID field of the frame as follows:

- If the frame is individually addressed, the recipient STA is known to be a member of a BSS (including being an AP), and that BSS's BSSID is known, the BSSID field shall be set to the BSS's BSSID or the wildcard BSSID value.
- Otherwise, the BSSID field of the frame shall be set to the wildcard BSSID value.

11.21 STAs communicating Data frames outside the context of a BSS

When dot11OCBActivated is true in a STA:

- a) Synchronization, authentication, association, and frame classes as defined in 11.1 and 11.3 are not used. Data confidentiality as defined in Clause 12 is not used. The STA may send Action frames and, if the STA maintains a TSF Timer, Timing Advertisement frames.
- b) The STA may send Control frames, except those of subtype PS-Poll, CF-End, and CF-End +CF-Ack.
- c) The STA may send Data frames of subtype Data, Null, QoS Data, and QoS Null.
- d) The STA shall set the BSSID field in all Management and Data frames to the wildcard BSSID value.

A STA with dot11OCBActivated equal to true shall not join or start a BSS.

Whenever MAC sublayer and PHY parameters are changed in a STA in which dot11OCBActivated is true, MAC sublayer and PHY operation shall resume with the appropriate MIB attributes in less than 2 TU.

A STA shall use information from the CF Parameter Set element of all received Beacon frames, without regard for the BSSID, to update its NAV as specified in 10.4.3.3.

11.22 Timing Advertisement

11.22.1 Introduction

A STA that sends a Timing Advertisement frame shall maintain a TSF Timer in order to set the Timestamp field in this frame. When a STA transmits the Timing Advertisement, Probe Response, or Beacon frame, the Timestamp shall be set to the value of the STA's TSF timer at the time that the data symbol containing the first bit of the Timestamp is transmitted to the PHY plus the transmitting STA's delays through its local PHY from the MAC-PHY interface to its interface with the WM (e.g., antenna).

A STA may advertise a time standard by transmitting a Timing Advertisement element in one of the following frames: Timing Advertisement, Probe Response, or Beacon. As defined in 9.4.2.61 the Time Advertisement element contains two estimates. The Time Value field contains an estimate of the difference between a time standard and the timestamp included in the same frame. The Time Error field contains an estimate of the standard deviation of the error in the estimate in the Time Value field. The time standard might be derived from an external time source. A STA with an external time source might implement an estimator in a variety of ways, which are beyond the scope of this standard.

11.22.2 Timing advertisement frame procedures

The SME provides the Time Advertisement element to the MLME when it requests the MLME to send a Timing Advertisement frame. When a Timing Advertisement frame is received by a STA, its MLME reports the Timestamp, Local Time, Time Advertisement element, and estimates of propagation delay to the SME. For a STA that maintains a TSF Timer and receives a Timing Advertisement frame, Local Time is the value of the STA's TSF timer at the start of reception of the first octet of the Timestamp field of the frame. Otherwise, the Local Time is unspecified. The receiving STA's SME might use the Timestamp, Local Time, and Time Advertisement element to align its estimate of the time standard to the transmitting STA's estimate of the corresponding time standard.

11.22.3 UTC TSF Offset procedures

When dot11UTCTSFOffsetActivated is true, the Time Advertisement and Time Zone elements shall be included in all Probe Response frames, and the Time Advertisement element shall be included in the Beacon frame every dot11TimeAdvertisementDTIMInterval DTIMs. When the dot11UTCTSFOffsetActivated is false, the Time Advertisement and Time Zone elements shall not be included in Beacon and Probe Response frames.

The AP should periodically synchronize to a UTC reference clock [B51] so that the UTC TSF offset can account for drift. The AP shall increment the Time Update Counter field value in the Time Advertisement element each time the synchronization occurs. The method the AP uses to synchronize with a UTC reference clock is out of scope of the standard.

11.23 Tunneled direct-link setup

11.23.1 General

Tunneled direct-link setup (TDLS) is characterized by encapsulating setup frames in Data frames, which allows them to be transmitted through an AP transparently. Therefore, the AP does not need to be direct-link capable, nor does it have to support the same set of capabilities that are used on the direct link between the two TDLS peer STAs. TDLS also includes power saving, in the form of TDLS peer PSM (scheduled) and TPU (unscheduled). STAs that set up a TDLS direct link remain associated with their BSS, but have the option of transmitting frames directly to the other TDLS peer STA.

Transmitting a TDLS frame through the AP means that the frame's RA is set to the BSSID. Transmitting a frame over the direct path means that the frame's RA is set to the MAC address of the TDLS peer STA.

To set up and maintain a direct link, both TDLS peer STAs shall be associated with the same infrastructure BSS.

A DMG STA shall not use the TDLS protocol.

A TDLS peer STA may be involved in direct links with multiple TDLS peer STAs at the same time. Simultaneous operation of DLS and TDLS between the same pair of STAs is not allowed. A DLS Request

frame shall not be transmitted to a STA with which a TDLS direct link is currently active. A DLS Request frame received from a STA with which a TDLS direct link is currently active shall be discarded.

The channel on which the AP operates is referred to as the *base channel*. If the AP operates in a 40 MHz channel, then the base channel refers to the primary channel. If the direct link is switched to a channel that is not the base channel, then this channel is referred to as the *off-channel*.

Features, excluding PCO, that are not supported by the BSS but that are supported by both TDLS peer STAs may be used on a TDLS direct link between those STAs. An example is the use of an HT MCS on a TDLS direct link between HT STAs when these STAs are associated with a non-HT BSS. Features that are supported by the BSS shall follow the BSS rules when they are used on a TDLS direct link on the base channel. The channel width of a TDLS direct link on the base channel shall not exceed the channel width of the BSS to which the TDLS peer STAs are associated, except when the TDLS Wider Bandwidth subfield in the Extended Capabilities element of the TDLS Setup Request frame or the TDLS Setup Response frame is 1 for both TDLS peer STAs.

A VHT STA with a TDLS link that is not an off-channel direct link shall use as its primary channel the primary channel or the only channel of its BSS. The channel width of a VHT TDLS link shall not be wider than the maximum channel width supported by either the TDLS initiator STA or the TDLS responder STA.

A 160 MHz bandwidth is defined to be identical to an 80+80 MHz bandwidth (i.e., one bandwidth is not wider than the other).

A STA shall not participate in a TDLS direct link with the same primary 80 MHz channel as the infrastructure BSS or another TDLS direct link of the STA but with a different secondary 80 MHz channel.

When admission control is required for an AC on the base channel, then the TDLS peer STA that intends to use this AC for direct-link transmissions on the base channel is responsible for setting up a TS with Direction of ‘Direct Link’ with the AP, as defined in 10.22.4.2.

A non-AP STA may act as TDLS initiator STA or TDLS responder STA when dot11TunneledDirectLinkSetupImplemented is true.

TDLS frames shall use the formatting as specified in 11.23.2 when they are transmitted through the AP and when they are transmitted over the TDLS direct link. A STA shall not transmit a TDLS Action field in a frame with the Type field of the frame set to Management. A received TDLS Action field in a frame with the Type field equal to Management shall be discarded. Note that the TDLS Discovery Response frame is not a TDLS frame but a Public Action frame.

TDLS shall not be used in an IBSS.

TDLS shall not be used in an MBSS.

Security is available on the TDLS direct link only when both TDLS peer STAs have an RSNA with the BSS.

TDLS shall not be used when the TDLS Prohibited subfield included in the Extended Capability element of the Association Response frame or Reassociation Response frame that led to the current association is equal to 1.

The HT Operation element shall be present in a TDLS Setup Confirm frame when both STAs are HT capable.

The VHT Operation element shall be present in a TDLS Setup Confirm frame when both STAs are VHT capable and the TDLS direct link is not established in the 2.4 GHz band. When the TDLS Setup Confirm frame includes a VHT Operation element, the Basic VHT-MCS And NSS Set field is reserved.

11.23.2 TDLS payload

TDLS uses Ethertype 89-0d frames, as defined in Annex H. The TDLS payload contains a TDLS Action field as is specified in 9.6.13. The UP shall be AC_VI, unless otherwise specified.

11.23.3 TDLS Discovery

To discover TDLS capable STAs in the same BSS, a TDLS initiator STA may send a TDLS Discovery Request frame to an individual DA, through the AP. The TDLS responder STA Address field contained in the Link Identifier element of the TDLS Discovery Request frame shall be set to the Destination Address of the TDLS Discovery Request frame. A TDLS capable STA that receives a TDLS Discovery Request frame with a matching BSSID in the Link Identifier element shall send a TDLS Discovery Response frame to the requesting STA, via the direct path. The TDLS responder STA Address field contained in the Link Identifier element of the TDLS Discovery Response frame shall be set to the MAC address of the STA sending the TDLS Discovery Response frame. A TDLS Discovery Request frame shall not be sent within dot11TDLSDiscoveryRequestWindow DTIM intervals after transmitting TDLS Discovery Request frame.

A TDLS STA may send an individually addressed TDLS Discovery Response frame via the direct path without prior reception of a TDLS Discovery Request frame. A TDLS STA that receives such an unsolicited TDLS Discovery Response frame may respond with an individually addressed TDLS Discovery Response frame.

A TDLS Discovery Request frame shall not be sent to a group address. A TDLS Discovery Response frame shall not be sent to a group address.

A TDLS STA may also send a TDLS Setup Request frame to a STA in the same BSS to discover whether the TDLS peer STA is TDLS capable or not. A TDLS Setup Response frame transmitted in response to TDLS Setup Request frame indicates that the TDLS peer STA sending the TDLS Setup Response frame is TDLS capable.

An alternative mechanism to discover TDLS capable STAs in the same BSS, is provided by the TDLS Capability ANQP-element, as described in 11.25.3.3.10. This mechanism allows the ANQP request/response frames to use the direct path between the peer STAs.

11.23.4 TDLS direct-link establishment

To establish a TDLS direct link, the TDLS initiator STA shall send a TDLS Setup Request frame to the intended TDLS responder STA.

TDLS Setup Request frames, TDLS Setup Response frames, and TDLS Setup Confirm frames shall be transmitted through the AP and shall not be transmitted to a group address.

Upon receipt of a TDLS Setup Request frame, the following options exist at the TDLS responder STA:

- a) The TDLS responder STA accepts the TDLS Setup Request frame, in which case the TDLS responder STA shall respond with a TDLS Setup Response frame with status code SUCCESS.
- b) The TDLS responder STA declines the TDLS Setup Request frame, in which case the TDLS responder STA shall respond with a TDLS Setup Response frame with status code REQUEST_DECLINED. A TDLS setup request shall be declined when the BSSID in the received Link Identifier does not match the BSSID of the TDLS responder STA.

- c) The TDLS Setup Request frame is received after sending a TDLS Setup Request frame and before receiving the corresponding TDLS Setup Response frame, and the source address of the received TDLS Setup Request frame is higher than its own MAC address, in which case the TDLS responder STA shall discard the frame and the TDLS responder STA shall send no TDLS Setup Response frame.
- d) The TDLS Setup Request frame is received after sending a TDLS Setup Request frame and before receiving the corresponding TDLS Setup Response frame, and the source address of the received TDLS Setup Request frame is lower than its own MAC address. In this case, the TDLS responder STA shall terminate the TDLS setup it initiated. The TDLS responder STA shall send a response according to item a) or item b) above in this case.
- e) If a TDLS Setup Request frame is received from a TDLS responder STA with which a currently active TDLS session exists, then the receiving STA shall tear down the existing TDLS direct link as if a TDLS Teardown frame was received, and respond with a TDLS Setup Response frame.

If no TDLS Setup Response frame is received within `dot11TDLSResponseTimeout`, or if a TDLS Setup Response frame is received with a status code not equal to `SUCCESS`, the TDLS initiator STA shall terminate the setup procedure and discard the TDLS Setup Response frame. Otherwise, the TDLS initiator STA shall send a TDLS Setup Confirm frame to the TDLS responder STA to confirm the receipt of the TDLS Setup Response frame.

When the BSS does not support EDCA, EDCA may be used on the direct link (on the base channel and on the off-channel), with the default EDCA Parameter Set, per 10.2.4.2.

If the STA has security enabled on the link with the AP, then the TPK handshake messages are included in the TDLS Setup frames, as follows:

- TPK handshake message 1 shall be included in the TDLS Setup Request frame.
- TPK handshake message 2 shall be included in the TDLS Setup Response frame.
- TPK handshake message 3 shall be included in the TDLS Setup Confirm frame.

When the TDLS setup handshake has been completed, the TDLS initiator STA and the TDLS responder STA are TDLS peer STAs. A TDLS peer STA shall accept Data frames received from the respective TDLS peer STA directly and Data frames destined for the respective TDLS peer STA may be transmitted over the direct link.

Subsequent to the successful completion of the TPK handshake, all frames transmitted and received on the TDLS direct link shall be protected using the TPKSA, per the procedures defined in Clause 12.

To avoid possible reordering of MSDUs, a TDLS initiator STA shall cease transmitting MSDUs to the TDLS responder STA through the AP after sending a TDLS Setup Request frame, and a TDLS responder STA shall cease transmitting MSDUs to the TDLS initiator STA through the AP after sending a TDLS Setup Response frame indicating status code `SUCCESS`.

The TDLS Setup Request frame and the TDLS Setup Response frame shall be transmitted using the lowest AC that was used for transmitting MSDUs to the respective TDLS peer STA during the previous `dot11TDLSACDeterminationInterval` seconds, or at `AC_BK`. When no MSDUs were transmitted during the previous `dot11TDLSACDeterminationInterval` seconds, then the TDLS Setup Request frame and the TDLS Setup Response frame may be sent at any AC, subject to applicable Admission Control rules.

If no TDLS Setup Response frame is received within `dot11TDLSResponseTimeout`, or if a TDLS Setup Response frame is received with status code other than `SUCCESS`, the TDLS initiator STA may resume transmitting MSDUs to the TDLS responder STA through the AP.

If a TDLS Setup Confirm frame is transmitted with a status code other than SUCCESS, the TDLS initiator STA may resume transmitting MSDUs to the TDLS responder STA through the AP.

If a TDLS Setup Confirm frame is received with a status code other than SUCCESS, the TDLS responder STA may resume transmitting MSDUs to the TDLS initiator STA through the AP.

A TDLS peer STA shall not transmit MSDUs over the direct link before transmitting or receiving a TDLS Setup Confirm frame with status code SUCCESS.

11.23.5 TDLS direct-link teardown

To tear down a direct link, a TDLS peer STA shall send a TDLS Teardown frame to the respective TDLS peer STA. A TDLS peer STA shall disable the direct link and delete the related security parameters after successfully transmitting TDLS Teardown frame. If the STA has security enabled on the link with the AP, then the FTE shall be included in the TDLS Teardown frame.

The TDLS Teardown frame shall be sent over the direct path and the reason code shall be set to TDLS_UNSPECIFIED_REASON except when the TDLS peer STA is unreachable via the TDLS direct link, in which case, the TDLS Teardown frame shall be sent through the AP and the reason code shall be set to TDLS_PEER_UNREACHABLE. If the direct link is on an off-channel when this condition occurs, then the TDLS peer STA may switch back to the base channel without initiating a channel switch frame exchange, before transmitting the TDLS Teardown frame.

If present, the contents of the FTE in the TDLS Teardown frame shall be the same as that included in the TPK handshake message 3 with the exception of the MIC field. The MIC shall be calculated on the concatenation, in the following order, of:

- Link Identifier element
- Reason Code
- Dialog token that was used in the MIC calculation for TPK handshake message 3
- Transaction Sequence number (1 octet) which shall be set to the value 4
- FTE, with the MIC field of the FTE set to 0

The MIC shall be calculated using the TPK-KCK and the AES-128-CMAC algorithm. The output of the AES-128-CMAC shall be 128 bits.

If the TPK handshake was successful for this TDLS session, then a receiving STA shall validate the MIC in the TDLS Teardown frame prior to processing the TDLS Teardown frame; a TDLS Teardown frame in which the MIC validation fails is called an *invalid* TDLS Teardown frame. A TDLS peer STA that receives a TDLS Teardown frame that is not an invalid TDLS Teardown frame shall disable the direct link and delete the related security parameters.

When a TDLS direct link gets torn down, any related TSs shall be deleted by the TDLS peer STAs.

A TDLS Teardown frame with Reason Code LEAVING_NETWORK_DEAUTH shall be transmitted to all TDLS peer STAs (via the AP or via the direct path) prior to transmitting a Disassociation frame or a Deauthentication frame to the AP. After receiving a Deauthentication frame or a Disassociation frame from the AP, a Deauthentication frame with Reason Code LEAVING_NETWORK_DEAUTH shall be transmitted via the direct path to all TDLS peer STAs that are in the awake state, if robust management frame protection has not been negotiated on the TDLS direct link.

11.23.6 TDLS channel switching

11.23.6.1 General

When a STA enables support for TDLS channel switching, it shall set dot11TDLSChannelSwitchingActivated, dot11MultiDomainCapabilityActivated and dot11ExtendedChannelSwitchActivated to true. When TDLS channel switching is enabled, the STA may set TDLS Channel Switching capability field to 1. The STA shall include a Supported Channels element and a Supported Operating Classes element in all TDLS Setup Request and TDLS Setup Response frames that have a TDLS Channel Switching capability field equal to 1. The STA shall include only channels in the Supported Channels element for which it can adhere to the local power constraint. A channel switch shall not be initiated by a STA when the TDLS peer STA did not set the TDLS Channel Switching capability field to 1 in the transmitted TDLS Setup Request frame or the TDLS Setup Response frame that caused the TDLS direct link to be set up.

TDLS Channel Switch Request frames and TDLS Channel Switch Response frames shall be transmitted over the TDLS direct link.

TDLS channel switching is different from (I)BSS channel switching as defined in 11.9.8.

The target channel is the destination channel of an intended channel switch. The target channel is specified by the STA that initiates a channel switch, from the set of operating classes supported by both TDLS peer STAs. The target channel and operating class are specified in the TDLS Channel Switch Request frame. The Country and Coverage Class settings on the target channel are the same as in the BSS to which both TDLS peer STAs are currently associated. Both STAs are entitled to request a channel switch. The events occurring for a channel switch are illustrated in Figure 11-31.

In Figure 11-31, the TDLS peer STAs (STA1 and STA2) are operating on an initial channel. After contending for the medium, STA1 transmits a TDLS Channel Switch Request frame to STA2, via the direct link, indicating a requested switch to a target channel. STA2 transmits an Ack frame (denoted ACK1 in Figure 11-31) after SIFS, and processes the TDLS Channel Switch Request frame. After contending for the medium, STA2 transmits a TDLS Channel Switch Response frame to STA1, possibly also after entering power save mode with the AP. STA1 responds with an Ack frame (denoted ACK2 in Figure 11-31) after SIFS. If the TDLS Channel Switch Response frame indicated with status code REQUEST_DECLINED, then both STAs continue to operate on the current channel. If the TDLS Channel Switch Response frame indicated with status code SUCCESS, then both STAs shall be listening on the target channel not later than SwitchTime after the end of the last symbol of ACK2, as measured on the WM. After switching channels, each TDLS peer STA shall perform a clear channel assessment (CCA) on the target channel, until a frame is detected by which it can set its NAV, or until a period of time equal to at least dot11TDLSSNavSync has transpired (this combined event is indicated as “ProbeTime” in Figure 11-31). The first transmission on the target channel shall be preceded by a random backoff, which shall start at the end of the ProbeTime. The first transmission on the new channel shall not start before the end of SwitchTime. The initiator of the channel switch shall transmit a Data frame on the target channel, unless the SwitchTimeout has expired or the responder to the channel switch transmitted a Data frame on the target channel.

If no successful frame exchange has occurred on an off-channel within SwitchTimeout after the end of the last symbol of ACK2, as measured on the WM, a STA shall go back to the base channel, where they shall be listening not later than SwitchTime after the end of the SwitchTimeout. After changing channels (either from the base channel to the off-channel or from the off-channel to the base channel), a TDLS peer STA shall perform CCA until a frame is detected by which it can set its NAV, or until a period of time equal to the ProbeTime has transpired.

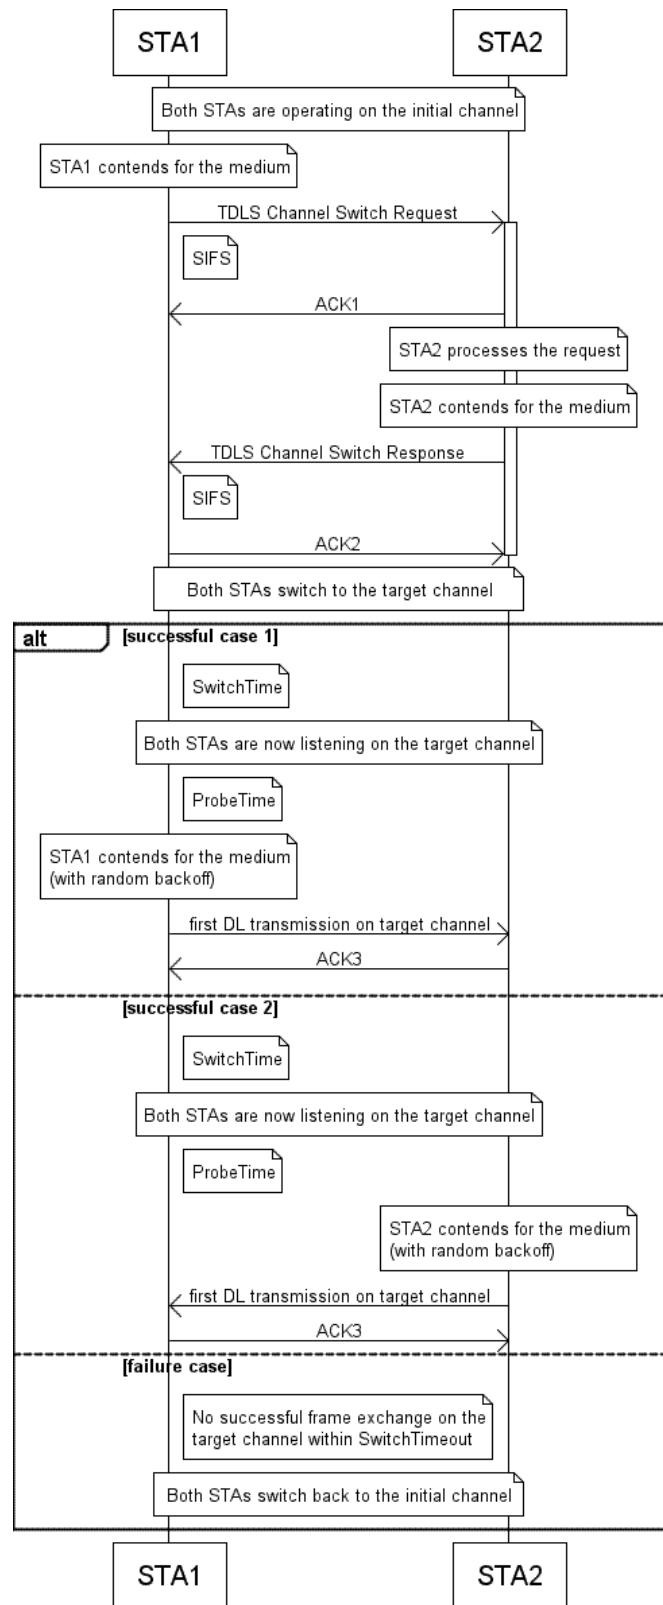

Figure 11-31—Events occurring for a TDLS direct-link channel switch

Both the TDLS Channel Switch Request frame and the TDLS Channel Switch Response frame shall contain a Channel Switch Timing element. The SwitchTime and SwitchTimeout values in the TDLS Channel Switch Timing element included in the TDLS Channel Switch Request frame shall specify the values required at the STA sending the TDLS Channel Switch Request frame. The SwitchTime and SwitchTimeout values specified in the TDLS Channel Switch Timing element included in the TDLS Channel Switch Response frame shall meet the requirements at the STA sending the TDLS Channel Switch Response frame and shall be equal to or larger than the values specified in the TDLS Channel Switch Request frame. The timing parameters specified in the Channel Switch Timing element included in the TDLS Channel Switch Response frame shall be used for the TDLS channel switching procedure. This procedure causes the larger of the two switch times to become the value that is transmitted in the TDLS Channel Switch Response frame.

The TDLS peer STA shall be in PS mode with the AP and shall not be involved in an active Service Period with the AP before sending a TDLS Channel Switch Request frame or a TDLS Channel Switch Response frame with Status Code set to SUCCESS. The TDLS peer STA that receives a TDLS Channel Switch Request frame may enter PS mode with the AP prior to sending the TDLS Channel Switch Response frame.

Because there is at least a backoff between the TDLS Channel Switch Request frame and the TDLS Channel Switch Response frame, there is a (small) probability that two STAs issue a TDLS Channel Switch Request frame at more or less the same time. To reduce the probability for this event to occur, a TDLS peer STA should not transmit a TDLS Channel Switch Request frame when a TDLS Channel Switch Request frame is received and no TDLS Channel Switch Response has been transmitted in response. If a TDLS Channel Switch Request frame is received from the TDLS peer STA to which a pending TDLS Channel Switch Request frame was previously sent before receiving TDLS Channel Switch Response, the TDLS initiator STA shall not reply to the TDLS Channel Switch Request frame and the TDLS responder STA shall reply to the TDLS Channel Switch Request frame.

If a TDLS Channel Switch Response frame does not imply a channel switch because the STAs already are on the requested channel, then the SwitchTime and ProbeTime may be skipped and both TDLS peer STAs continue to operate on the requested channel. To cross means that a TDLS Channel Switch Request frame is received from a peer STA after transmitting a TDLS Channel Switch Request frame to the TDLS peer STA, instead of the expected TDLS Channel Switch Response frame.

When a TDLS peer STA does not receive an acknowledgment to a TDLS Channel Switch Response frame, it may retransmit the frame but the number of retransmissions shall be lesser of the maximum retry limit and dot11TDLSPeerSTAMissingAckRetryLimit.

A channel switch from an off-channel to the base channel may be accomplished by sending a TDLS Channel Switch Response frame indicating the base channel as the target channel, without prior TDLS Channel Switch Request frame. The Channel Switch Timing element shall be the same as contained in the Channel Switch Response frame that caused the switch to the off-channel.

TDLS Channel Switching shall not be used when the TDLS Channel Switching Prohibited subfield included in the Extended Capability element of the Association Response frame or Reassociation Response frame that led to the current association is equal to 1.

11.23.6.2 General behavior on the off-channel

If dot11SpectrumManagementRequired is true, a TDLS peer STA shall not transmit a TDLS Channel Switch request specifying an off-channel where radar detection is required, unless the STA has tested that channel for the presence of radar, according to regulatory requirements. If a TDLS peer STA that is operating in such a channel detects radar, the TDLS peer STA shall discontinue transmissions according to regulatory requirements, and it shall send a TDLS Channel Switch Request frame indicating a switch to the base channel. The channel switch avoids an interruption on the direct link.

The TDLS peer STA initiating the switch to the channel where radar detection is required by regulation shall be the DFS owner.

The secondary channel of an existing 40 MHz network shall not be selected as an off-channel.

On an off-channel, the TDLS peer STAs remain associated with their BSS, so the BSSID remains the same.

It is recommended that in general TDLS STAs propose target channels that have no detectable medium occupancy. If no such channel is available, then it is recommended that the TDLS STA propose a target channel where beacons are detected but with little or no additional medium occupancy. It is further recommended that TDLS STAs do not propose a target channel where the presence of beacons indicate that ACM bits are set, unless little or no additional medium occupancy is detected.

11.23.6.3 Setting up a 40 MHz direct link

11.23.6.3.1 General

A 40 MHz off-channel direct link may be started if both TDLS peer STAs indicated 40 MHz support in the Supported Channel Width Set field of the HT Capabilities element (which is included in the TDLS Setup Request frame and the TDLS Setup Response frame).

Switching to a 40 MHz off-channel direct link is achieved by including the following information in the TDLS Channel Switch Request frame:

- Operating Class field indicating 40 MHz Channel Spacing
- Secondary Channel Offset field indicating SCA or SCB

A 40 MHz off-channel direct link shall not be established in the 2.4 GHz band.

The TDLS peer STA initiating the switch to the 40 MHz off-channel shall be the DO.

11.23.6.3.2 Basic 40 MHz functionality

TDLS peer STAs may transmit 40 MHz PPDU on a 40 MHz direct link. A TDLS peer STA shall not transmit a 20 MHz PPDU in the secondary channel of its 40 MHz direct link.

11.23.6.3.3 Channel selection for a 40 MHz direct link

If a TDLS peer STA chooses to start a 40 MHz direct link that occupies the same two channels as an existing 40 MHz network (i.e., a 20/40 MHz BSSs or a 40 MHz direct link), then it shall select primary and secondary channels of the new direct link that are identical to the primary and secondary channels of the existing 40 MHz network, unless the TDLS peer STA discovers that on these two channels there are existing 40 MHz networks with different primary and secondary channels.

If a TDLS peer STA chooses to start a 40 MHz direct link, the selected secondary channel should correspond to a channel on which no beacons are detected.

11.23.6.3.4 Switching from a 40 MHz to a 20 MHz direct link

Switching from a 40 MHz off-channel direct link to a 20 MHz off-channel direct link is established through a TDLS channel switch. When on a 40 MHz off-channel direct link, a requested switch to a 20 MHz direct link shall always be accepted.

11.23.6.3.5 CCA sensing and NAV assertion in a 40 MHz direct link

When active on a 40 MHz direct link, a TDLS peer STA shall follow the CCA rules as defined in 11.16.9 and the NAV rules as defined in 11.16.10.

11.23.6.4 TDLS channel switching and power saving

A TDLS direct link shall not be switched to an off-channel during a TPU service period. While on an off-channel, a TDLS peer STA shall not enter TPU power save mode.

A TDLS direct link may be switched to an off-channel when TDLS peer PSM is active on the link. The wakeup windows occur on the off-channel in the same way they would have occurred had the STAs remained on the base channel. Suspension of the wakeup windows implies a switch back to the base channel.

11.23.6.5 Setting up a wide bandwidth off-channel direct link

11.23.6.5.1 General

A wideband off-channel TDLS direct link is a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz off-channel TDLS direct link.

A wideband off-channel TDLS direct link may be started if both TDLS peer STAs indicated wideband support in the VHT Capabilities element VHT Capabilities Information field included in the TDLS Setup Request frame or the TDLS Setup Response frame.

Switching to a wideband off-channel direct link is achieved by including any of the following information in the TDLS Channel Switch Request frame:

- An Operating Class element indicating 40 MHz Channel Spacing and a Secondary Channel Offset element indicating SCA or SCB
- A Wide Bandwidth Channel Switch element indicating 80 MHz, 160 MHz, or 80+80 MHz channel width

The operating class in TDLS Channel Switch Request frame shall have a value representing 5 GHz for the channel starting frequency.

A TDLS peer STA that is extended spectrum management capable and that announces new TPC parameters that come into effect at the same time as the switch to an off-channel direct link, shall include at least one Transmit Power Envelope element in the transmitted the TDLS Channel Switch Request frame. The recipient TDLS peer STA that is extended spectrum management capable and that has dot11SpectrumManagementRequired or dot11RadioMeasurementActivated equal to true shall use the parameters in these received element(s) in the recipient STA's TPC calculations for the off-channel direct link.

When announcing new operating classes or both a new operating class table index and new operating classes that come into effect at the same time as the switch to the direct link and that express new regulatory requirements, the TDLS peer VHT STA initiating the switch shall include a Country element in a transmitted TDLS Channel Switch Request frame. The Country element shall contain all of the Operating Classes for the off-channel direct link in Operating Triplet fields and zero Subband Triplet fields. The Country element shall include one Operating Triplet field that contains the same Operating Class as the Operating Class field in the same frame. The country indicated by the Country string in the TDLS Channel Switch Request frame shall be equal to the country indicated by the Country string of the BSS. The recipient TDLS peer VHT STA that has dot11MultiDomainCapabilityActivated,

dot11SpectrumManagementRequired, or dot11RadioMeasurementActivated equal to true shall use the parameters in the received Country element in the TDLS Channel Switch Request frame in order to maintain regulatory compliance.

The TDLS peer STA initiating the switch to the wideband off-channel shall be the DO on that channel.

11.23.6.5.2 Basic wideband functionality

TDLS peer STAs may transmit up to 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz PPDUs on a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz direct link, respectively. A TDLS peer STA shall not transmit a 20 MHz PPDU in the nonprimary channel of its 80 MHz, 160 MHz, or 80+80 MHz direct link.

A TDLS peer STA shall not transmit a 40 MHz PPDU that does not use the primary 40 MHz channel of its 80 MHz, 160 MHz, or 80+80 MHz direct link. A TDLS peer STA shall not transmit an 80 MHz PPDU that does not use the primary 80 MHz channel of its 160 MHz or 80+80 MHz direct link.

11.23.6.5.3 Channel selection for a wideband off-channel direct link

If a TDLS peer STA chooses to start a wideband direct link, the TDLS peer STA shall follow the primary channel selection rules defined in 11.40.2 and 11.24.15 and the secondary 80 MHz channel rule defined in 11.23.1.

11.23.6.5.4 Switching from a wideband to a 20 MHz direct link

Switching from a wideband off-channel direct link to a 20 MHz off-channel direct link is established through a TDLS channel switch. A STA operating on a wideband off-channel direct link shall accept a requested switch to a 20 MHz direct link.

11.23.6.5.5 CCA sensing and NAV assertion in a 20 MHz, 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz direct link

TDLS peer VHT STAs shall follow the CCA rules defined in 10.3.2.6, 10.22.2.7, and 10.22.3 and the NAV rules defined in 11.40.5.

11.24 Wireless network management procedures

11.24.1 Wireless network management dependencies

When dot11WirelessManagementImplemented is true, the STA is a WNM STA and dot11ExtendedChannelSwitchActivated and dot11RadioMeasurementActivated shall be true. This subclause describes WNM procedures for requesting and reporting WNM capabilities between STAs that support WNM procedures.

When dot11WirelessManagementImplemented is true, and one or more of bit 7 to bit 27 in the Extended Capabilities element have the value 1, the Extended Capabilities element shall be included in Beacon frames, Association Request and Response frames, Reassociation Request and Response frames, and Probe Request and Response frames. When dot11WirelessManagementImplemented is true, for each bit 7 to bit 27 in the received Extended Capabilities element that is 0, a STA shall not request the corresponding feature from the sending STA. A WNM STA receiving a request for a WNM feature from another STA shall reject the request if the receiving WNM STA has not advertised support for the corresponding WNM feature.

11.24.2 Event request and report procedures

11.24.2.1 Event request and event report

The Event Request and Event Report frames enable network real-time diagnostics. A STA whose dot11EventsActivated is true shall support event requests and reports and shall set to 1 the Event field of the Extended Capabilities elements that it transmits. If dot11EventsActivated is true, a STA shall log all Transition, RSNA, peer-to-peer, and WNM log events, including the corresponding TSF, UTC Offset and Event Time Error.

The STA log of events shall not be cleared as a result of BSS transitions. However, if the STA moves to a different ESS or IBSS, the STA shall delete all event log entries.

A STA that supports event reporting may send an Event Request or Event Report frame to a STA within the same infrastructure BSS or the same IBSS whose last received Extended Capabilities element contained a value of 1 for the Event bit in the Extended Capabilities field; it shall not send an Event Request or Event Report frame otherwise. If the STA receives an Event Request frame without error and it supports event reporting, it shall respond with an Event Report frame that includes a value of the Dialog Token field that matches the one in the Event Request frame.

The permitted source and destination STAs for an Event Request frame are shown in Table 11-9.

An AP may include zero or more Event Request elements in an Event Request frame. Each Event Request element contains an Event Token that associates this Event Request with any subsequent Event Report elements. When sending Event Report elements, a STA shall use the same Event Token that was included in the original request.

Only a single Event Request frame from a STA is outstanding at a given STA at any time. If a STA that supports event reporting receives a subsequent Event Request frame with a different dialog token before completing the Event Report for the previous request from the requesting STA, the receiving STA may respond to the most recent request frame; it shall not respond to a request frame that is not the most recent one.

Upon a BSS transition, the STA shall cancel any event requests in the latest Event Request frame.

The Event Request elements can contain conditions that specify events to be reported and conditions that establish event reporting when a STA experiences problems or failures. A STA sends an Event Request frame containing one or more Event Request elements, each of which contains zero or more subelements. Subelements are defined for each event type. A STA shall include in the corresponding Event Report element only those events that meet the specified event conditions within the current ESS or IBSS.

In each Event Report element, a STA shall include a Status field that indicates the result of the event request/report transaction. If the STA is able to return one or more Event Report elements, then the STA shall return a value of “Successful” in the Event Report element. If the STA has no logged events of the requested type, the STA shall return a value of Successful in the Event Report element without an event included in the Event Report field. If the STA is unable to process the request at that time, the STA shall return a value of “Request failed” in the Event Report element. If a STA refuses an event request, the STA shall return a value of “Request refused” in the Event Report element. The reasons for refusing an event request are outside the scope of this standard but may include reduced quality of service, unacceptable power consumption, measurement scheduling conflicts, or other significant factors. If the STA is incapable of generating an Event Report of the type specified in the Event Request frame, the STA shall return a value of “Request incapable” indicating that the requester should not request again.

If the Event Report elements do not fit into a single MMPDU, the reporting STA shall send the remaining elements in additional Event Report frames until all Event Report elements have been returned to the requesting STA. In any subsequent Event Report frame and for all remaining Event Report elements a reporting STA shall include the same values of the Dialog Token and Event Token fields, respectively, that was sent in the corresponding Event Request frame. When multiple MMPDUs are required, the non-AP STA shall include complete Event Report elements and shall not fragment an element across multiple MMPDUs.

A STA shall transmit both the Event Request frame and the Event Report frame only with an individually addressed destination address. In an infrastructure BSS, only an AP shall transmit an Event Request frame to a non-AP STA. An AP that supports event reporting shall discard received Event Request frames.

When a STA transmits an Event Request frame to another STA it shall indicate the types of events requested by setting the Event Type field and shall indicate the maximum number of logged events to report by using the Event Response Limit field in each included Event Request element. If the number of available logged events of the requested type exceeds the Event Response Limit, the STA shall report an Event Response Limit number of the most recent events. If there are no available logged events of the type specified in the Event Request frame, the STA shall send the Event Report frame without any Event Report element. The reporting STA shall send all available Event Report elements for the requested Event Type when the Event Request field is not present in the Event Request element.

A STA may include a Destination URI element in the Event Request frame. The AP includes the URI in the Destination URI element that the reporting non-AP STA may use to send Event Reports, upon the loss or interruption of connectivity to the BSS.

On receipt of an Event Request frame with an Destination URI element, the reporting non-AP STA SME may send the Event Report to the AP using the Destination URI with another network interface (if available). The non-AP STA SME shall not send the Event Report to the URI contained in the Destination URI element except after detecting loss of BSS connection.

The non-AP STA shall determine loss of connection to the AP that issued the Event Request frame when it has not detected any Beacon frames from the AP for a period no less than the ESS Detection Interval.

If the BSS connection is reestablished to the AP that transmitted the Event Request frame, the non-AP STA shall transmit the corresponding Event Report frame to the AP without using the Destination URI.

When the non-AP STA uses the Destination URI mechanism, it shall transport the Frame Body field of the Event Report frame using the URI given in the Destination URI Element. An example use of the Destination URI is given in Annex Q.

11.24.2.2 Transition event request and report

The Transition Event report provides information on the previous transition events for a given non-AP STA. The Transition Event request and report are only permitted in the infrastructure BSS.

Each STA supporting the Transition Event shall log up to the last five Transition events occurring since the STA associated to the ESS. A STA may log more than five of the most recent Transition events.

Upon receipt of an Event Request frame containing an Event Request element including a Transition Event request, the non-AP STA shall respond with an Event Report frame that includes available Event Report elements within the current ESS for the Transition event type.

Transition Event Request subelements are used to specify conditions for reporting of transition events. If any Transition Event Request subelements are present in the Event Request frame, the reporting non-AP

STA shall include in the Event Report frame only those available Transition Event Report elements that meet the transition event reporting condition(s) specified in the Event Request frame. If no transition event subelements are present in the Event Request field, the reporting STA shall include all available Transition Event Report elements.

A Frequent Transition subelement in an Event Request frame defines conditions for frequent transition. Frequent transition occurs when the number of BSS transitions exceeds the value of the Frequent Transition Count Threshold within the indicated Time Interval value as defined in the Frequent Transition subelement in 9.4.2.67.2. A STA that receives a Frequent Transition subelement shall, at each BSS transition, apply the conditions for frequent transition to the log of transition events. If the logged transition events meet the conditions for frequent transition, the STA shall send an Event Report frame including a Transition Event Report element with Event Report Status set to Detected Frequent Transition and include in that Event Report element the last logged transition event.

For transition logging and reporting purposes, the transition time is defined as the time difference between the starting time and the ending time of a transition between APs, even if the transition results in remaining on the same AP.

The starting time is one of the following items:

- The start of a search for an AP, when the transition reason is 4 (first association to WLAN).
- The latest time that a frame could have been transmitted or received on the source BSS.
- The start of a search for an AP, after determination that a transition has failed.

The ending time is one of the following items:

- The earliest time that a Data frame can be transmitted or received on the target BSS, after completion of RSN, IEEE 802.1X, or other authentication and key management transmissions, when such are required by the target BSS.
- The time that a determination is made that the transition has failed.

11.24.2.3 RSNA event request and report

The RSNA Event Report provides authentication events for a given non-AP STA. The RSNA Event Request and Report are only permitted in an infrastructure BSS.

Each STA supporting the RSNA Event shall log up to the last five RSNA events occurring since the STA associated to the ESS. A STA may log more than five of the most recent RSNA events.

Upon receipt of an Event Request frame containing an Event Request element including an RSNA Event request, the non-AP STA shall respond with an Event Report frame that includes available Event Report elements within the current ESS for the RSNA event type.

If an RSNA Event Request subelement is present in the Event Request field, the reporting non-AP STA shall include available Event Report elements that meet the specified condition for the RSNA event type. If no RSNA Event Request subelement is present in the Event Request field, the reporting STA shall include all available RSNA Event Report elements.

11.24.2.4 Peer-to-peer link event request and report

The peer-to-peer link event report provides peer-to-peer connectivity events for a given non-AP STA. A peer-to-peer event occurs when a peer-to-peer link is initiated or terminated.

Each STA supporting the peer-to-peer event shall log up to the last five peer-to-peer events occurring since the STA associated to the ESS or IBSS. A STA may log more than five of the most recent peer-to-peer events. When a link is initiated, a STA shall log and record the TSF time of the peer-to-peer event without a connection time. When a peer-to-peer link is terminated, a STA shall log the peer-to-peer link event including the connection time for the terminated link and shall delete from the log any initiation event for the same peer-to-peer link.

Upon receipt of an Event Request frame containing an Event Request element including a peer-to-peer link event request, the non-AP STA shall respond with an Event Report frame that includes available Event Report elements within the current ESS or IBSS for the peer-to-peer event type. When a STA includes a Peer-to-Peer Event Report element for a link initiation, the STA shall include a connection time for the event report element which indicates the time difference from the event timestamp to the current time.

If a Peer-to-Peer Link Event Request subelement is present in the Event Request field, the reporting non-AP STA shall include available Event Report elements that meet the specified condition for the Peer-to-Peer event type. If no Peer-to-Peer Link Event Request subelements are present in the Event Request field, the reporting STA shall include all available Peer-to-Peer Event Report elements.

11.24.2.5 WNM log event request and report

The WNM log event report is intended to capture PHY and MAC layer events related to the operation of those layers in vendor-specific, human-readable (ASCII text) form. The WNM log is a general reporting mechanism that can apply to configuration or monitoring behavior for PHY and MAC. The WNM log is particularly useful for logging success or failure events across areas such as driver status, IEEE 802.11 or IEEE 802.1X authentication, authorization, status changes while associated or unassociated.

For example:

```
<0>Oct 03 17:47:00 00:01:02:03:04:05 Adapter DLL Service initialized
<1>Oct 03 17:48:40 00:01:02:03:04:05 Authentication started
<1>Oct 03 17:48:46 00:01:02:03:04:05 IEEE 802.1X Authentication Failed, credential failure
<1>Oct 03 17:49:00 00:01:02:03:04:05 Authentication success
```

A non-AP STA that supports event reporting may be queried at any time for its current set of WNM log messages. The WNM log messages returned by the non-AP STA may provide insight into the trouble being experienced by non-AP STA.

Upon receipt of an Event Request frame containing an Event Request element including a WNM log event request, the non-AP STA shall respond with an Event Report frame that includes WNM Log Event Report elements.

11.24.2.6 Vendor Specific event request and report

The procedures for use of the Vendor Specific Event Request and Report are vendor specific and are not part of this standard.

11.24.3 Diagnostic request and report procedures

11.24.3.1 Diagnostic request and diagnostic report

The Diagnostic Request and Diagnostic Report protocol provides a tool to diagnose and debug complex network issues. A STA whose dot11DiagnosticsActivated is true shall support diagnostic reporting and shall set to 1 the Diagnostics field of the Extended Capabilities elements that it transmits.

A STA that supports diagnostics reporting shall send a Diagnostics Request or Diagnostics Report frame to a STA within the same infrastructure BSS or the same IBSS whose last received Extended Capabilities element contained a value of 1 for the Diagnostics bit in the Extended Capabilities field; it shall not send a Diagnostics Request or Diagnostics Report frame otherwise.

The Diagnostic Request frame contains a unique Dialog Token. A value of the Dialog Token field of 0 is a reserved value and shall not be used. The source and destination of a Diagnostic Request frame shall both be members of the same BSS. The permitted source and destination STAs for a Diagnostic Request frame are shown in Table 11-9. A STA may include one or more Diagnostic Request elements in a Diagnostic Request frame. Each Diagnostic Request element contains a unique Diagnostic Token that identifies the element within the Diagnostic Request frame.

If a STA that supports diagnostic reporting receives a Diagnostic Request frame without error, the STA shall respond with a Diagnostic Report frame that includes a value of the Dialog Token field that matches the one in the Diagnostic Request frame. Each Diagnostic Report element that corresponds to the Diagnostic Request element shall contain the same Diagnostic Token that was included in the original request.

Only a single Diagnostic Request frame from a STA is outstanding at a given STA at any time. If a STA receives a subsequent Diagnostic Request frame with a different dialog token before completing the Diagnostic Report for the previous request from the requesting STA, the STA shall respond to the most recent Diagnostic Request frame; the STA shall not respond to a Diagnostic Request frame that is not the most recent one.

All outstanding diagnostic requests, as indicated by received MLME-DIAGREQUEST.indication primitives, are canceled upon a BSS transition, except when the BSS transition occurs as a result of responding to or initiating a diagnostic request. All outstanding diagnostic requests, as indicated by received MLME-DIAGREQUEST.indication primitives, are canceled after the time indicated in the Diagnostic Timeout field, in the Diagnostic Request frame. When a STA that supports diagnostic reporting receives a Diagnostic Request frame with a Diagnostic Request Type of Cancel Diagnostic Request, the STA cancels all outstanding diagnostic requests, and discards all pending diagnostic reports, as indicated by received MLME-DIAGREQUEST.indication primitives.

All Diagnostic Report elements shall include a Status field that indicates the overall result of the transaction. If the STA is able to complete the diagnostic request made in the Diagnostic Request element, then a value of “Successful” shall be returned. If the STA is unable to process the request at that time a value of “Fail” shall be returned. If the STA is incapable of generating a report of the type specified, it shall return a value of “Incapable.” If the STA cannot support the request for any other reason, the value of Refused shall be returned.

A STA shall transmit both the Diagnostic Request frame and the Diagnostic Report frame with an individually addressed destination address.

A STA may include a Destination URI element in the Event Request frame. The AP includes the URI in the Destination URI element that the reporting non-AP STA may use to send Diagnostic Reports, upon the loss or interruption of connectivity to the BSS.

On receipt of an Diagnostic Request frame with an Destination URI element, the reporting non-AP STA SME may send the Diagnostic Report to the AP using the Destination URI with another network interface (if available).

The non-AP STA shall determine loss of connection to the AP that issued the Diagnostic Request frame when it has not detected any Beacon frames from the AP for a period no less than the ESS Detection Interval.

If the BSS connection is reestablished to the AP that transmitted the Diagnostic Request frame, the non-AP STA shall transmit the corresponding Diagnostic Report frame to the AP without using the Destination URI.

When the non-AP STA uses the Destination URI mechanism, it shall transport the payload of the Diagnostic Report frame using the URI given in the Destination URI Element. An example use of the Destination URI is given in Annex Q.

If a non-AP STA that receives an Destination URI subelement in an Diagnostic Request fails to detect any Beacon frames, belonging to the AP that issued the request for a Diagnostic report, for the period specified by the ESS detection interval, it may use the URI specified in the Destination URI subelement to transport the Diagnostic Report to the AP.

If the Diagnostic Report elements do not fit into a single MMPDU, the reporting STA shall send the remaining elements in additional frames until all Diagnostic Report elements have been returned to the requesting STA. A STA shall include the same values of the Dialog Token and Diagnostic Token fields that were transmitted in the corresponding Diagnostic Request frame in each subsequent Diagnostic Report frame and Diagnostic Report elements. When multiple MMPDUs are required, the STA shall include complete Diagnostic Report elements and shall not fragment an element across multiple MMPDUs.

A STA that supports diagnostic reporting may cancel a previously sent Diagnostic Request frame for which it has not yet received a Diagnostic Report frame by sending a Diagnostic Request frame with the Diagnostic Request Type field value of 0, indicating “Canceled,” to the STA to which it previously sent the Diagnostic Request frame. A STA that supports diagnostic reporting shall inform a STA from which it has previously received a Diagnostic Request frame that the request has been locally canceled by sending a Diagnostic Report frame with the Diagnostic Status field set to a value of 4, indicating “Canceled,” to the requesting STA. In a Diagnostic Request frame with the Diagnostic Request Type field value of 0, and a Diagnostic Report frame with the Diagnostic Status field set to a value of 4, no Diagnostic subelements are included in the Diagnostic Request or Response element.

11.24.3.2 Configuration Profile report

The Configuration Profile report enables an AP to discover the current profile in use for an associated device, and additional profiles for the current ESS. A non-AP STA that supports diagnostic reporting and receives a Configuration Profile report request type shall respond with a Diagnostic Report frame that includes all available Diagnostic elements allowed for the type.

Devices that support multiple configuration profiles for an ESS may include multiple Diagnostic Report elements in a single Diagnostic Report frame (or multiple frames if required). Each Diagnostic Report element shall contain a Profile ID element that uniquely identifies the configuration profile(s) for the current ESS that are available on the device.

11.24.3.3 Manufacturer information STA report

The Manufacturer Information STA Report enables an AP to discover static manufacturer specific data about an associated STA device. A non-AP STA that supports diagnostic reporting and receives a Manufacturer Information STA Report request type shall respond with a Diagnostic Report frame that includes all available Diagnostic elements allowed for the type.

When more than one Antenna Type/Antenna Gain pair is enabled, multiple Antenna Type subelements shall be included in the Manufacturer Information STA Report Diagnostic Report element.

When more than one Collocated Radio Type, or Device Type is supported, multiple Collocated Radio Type subelements, or Device Type subelements shall be included in the Manufacturer Information STA Report

Diagnostic Report element. If the existence or the type of collocated radio is unknown, no Collocated Radio Type subelements shall be included.

11.24.3.4 Association diagnostic

The purpose of the association diagnostic is to determine that a STA is able to associate with a designated BSS. This test directs an association to be completed with a specific AP.

To initiate the test, an AP that supports diagnostic reporting shall send a Diagnostic Request frame containing a Diagnostic Request Type field set to 3 (i.e., Association Diagnostic) to a STA that supports diagnostic reporting. The AP shall not send an association diagnostic request with a designated BSS that is not part of the ESS and the STA receiving an association diagnostic request shall reject requests to perform diagnostics on a BSS that is not part of the ESS. All parameters required to complete the association are included in the Diagnostic Request element.

Upon receipt of the Diagnostic Request frame containing a Diagnostic Request element specifying an association request, the STA determines whether to accept the request. If the STA declines the request, it shall send a Diagnostic Report frame with the Status field of a Diagnostic Report element set to Refused. If the STA accepts the request, it shall cause an authentication to occur to the AP indicated in the Diagnostic Request element and the STA's SME shall issue an MLME-DIAGREPORT.request primitive, indicating the results of the diagnostic.

One means to cause an authentication to occur is for the STA's SME to issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the current AP, and an MLME-AUTHENTICATE.request primitive to authenticate to the AP indicated in the Diagnostic Request element. If successful, the STA shall issue an MLME-(RE)ASSOCIATE.request primitive to associate with the AP indicated in the Diagnostic Request element. If successful, the STA's SME shall then issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the AP indicated in the Diagnostic Request element, reassociate with the AP from which it received the Diagnostic Request, and issue an MLME-DIAGREPORT.request primitive, indicating the results of the diagnostic.

11.24.3.5 IEEE 802.1X authentication diagnostic

The purpose of the IEEE 802.1X authentication diagnostic is to determine that the STA is able to complete an IEEE 802.1X authentication with a designated BSS. This test directs an association and IEEE 802.1X authentication to be completed with a specific AP. If a STA that supports diagnostic reporting also supports RSN, the STA shall support the IEEE 802.1X authentication diagnostic.

To initiate the test, an AP that supports diagnostic reporting shall send a Diagnostic Request frame containing a Diagnostic Request Type field set to 4 (i.e., IEEE 802.1X Authentication Diagnostic) to a STA that supports diagnostic reporting. A STA that supports diagnostic reporting in an IBSS or an AP that supports diagnostic reporting shall not send an IEEE 802.1X authentication diagnostic request with a designated BSS that is not part of the ESS, or IBSS and a STA that supports diagnostic reporting which receives a diagnostic request shall reject requests to perform diagnostics on other networks. The AP, EAP method and credential type values included in the AP Descriptor, EAP Method and Credential Type subelements in the Diagnostic Request element shall be used to complete the association and IEEE 802.1X authentication.

Upon receipt of the Diagnostic Request frame containing a Diagnostic Request element specifying an IEEE 802.1X Authentication Diagnostic request, the STA determines whether to accept the request. If the STA declines the request, it shall send a Diagnostic Report frame with the Status field of a Diagnostic Report element set to Refused. If the STA accepts the request, it shall cause an IEEE 802.1X authentication to occur to the AP indicated in the Diagnostic Request element and the STA's SME shall issue an MLME-DIAGREPORT.request primitive indicating the results of the diagnostic.

One means to cause an authentication to occur is for the STA's SME to issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the current AP, and an MLME-AUTHENTICATE.request primitive to authenticate to the AP indicated in the Diagnostic Request element. If successful, the STA shall issue an MLME-(RE)ASSOCIATE.request primitive to the AP indicated in the Diagnostic Request element. If (re)association succeeds, the STA shall try to complete IEEE 802.1X authentication using parameters specified in the Diagnostic Request element. The STA shall then issue an MLME-DEAUTHENTICATE.request primitive to deauthenticate from the AP indicated in the Diagnostic Request element, reassociate with the AP from which it received a diagnostic request, and issue an MLME-DIAGREPORT.request primitive, indicating the results of the diagnostic.

11.24.4 Location track procedures

11.24.4.1 Location track configuration procedures

A STA whose dot11LocationTrackingActivated is true shall support location tracking and shall set to 1 the Location field of the Extended Capabilities elements that it transmits.

In an infrastructure BSS, a non-AP STA shall not transmit Location Configuration Request frames.

A STA that supports location may configure another STA to transmit Location Track Notification frames for the purpose of tracking the receiving STA's location by sending Location Indication Channels, Location Indication Interval and Location Indication Broadcast Data Rate subelements in a Location Parameters element in a Location Configuration Request frame. The minimum Normal and In-Motion Report Interval in a Location Configuration Request frame is 500 ms.

A STA may transmit the Location Configuration Request frame as a broadcast or individually addressed frame. A STA that supports location and receives a broadcast Location Configuration Request frame shall send a Location Configuration Response frame if the STA does not accept the parameters included in the Location Configuration request; the STA shall not send a Location Configuration Response frame if it accepts the parameters included in the Location Configuration request.

A STA that supports location and receives an individually addressed Location Configuration Request frame shall respond with a Location Configuration Response frame. Upon reception of a new Location Configuration Request frame, the STA shall override any information from a previously received Location Configuration Request frame with the new frame. If all Location Parameter subelements included in the Location Configuration Request frame are successfully configured on the receiving STA, then the STA shall include in the Location Configuration Response frame a single Location Status subelement indicating success. Upon successful configuration, the receiving STA shall start transmitting the Location Track Notification frames based on the Location Configuration Request frame parameters, as described in 11.24.4.2. If one or more Location Parameter subelements are unsuccessfully configured, then the STA shall include in the Location Configuration Response frame a Location Status subelement for each failed subelement indicating the subelement ID, the status value and the corresponding Location Parameter subelement as described in the paragraphs that follow.

The Location Status subelement has four possible status values: Success, Fail, Refused and Incapable. When the requesting STA receives a Location Configuration Response frame with Location Status indicating anything other than Success, the requesting STA shall assume the original request was not processed and no configuration took effect on the receiving STA and the requesting STA should take appropriate action based on the status value returned.

For Location Status Fail:

- If the receiving STA has been configured successfully prior to the current Location Configuration Request and continues to transmit Location Track Notification frames based on those parameters, the STA shall respond with its current Location Parameters subelements values.
- If the STA has no previously configured value, the STA shall respond with its minimum Location Parameters subelements that it is capable of supporting.
- The configuring STA may either retry the original request or send an alternate request.

For Location Status Incapable:

- The STA responding to the configuration request may include the minimum Location Parameters subelements that it is capable of supporting.
- The configuring STA shall not send another configuration request matching the previous configuration request while the reporting STA is associated to the same BSS.
- The configuring STA may send an alternate request.

For Location Status Refuse:

- The STA responding to the configuration request may include the minimum Location Parameters subelements that it is capable of supporting.
- The configuring STA may send an alternate request.

The location configuration methods, from highest to lowest precedence, are as follows: 1) an individually addressed Location Configuration Request frame, 2) broadcast Location Configuration Request frame. When a STA receives a new Location Configuration frame at the same or higher precedence than the previous it shall cancel the previous configuration and begin using the newest configuration.

The Location Indication Broadcast Data Rate subelement included in Location Configuration Request frames indicates the target data rate at which the STA shall transmit Location Track Notification frames. The Location Indication Broadcast Data Rate included in the Location Configuration Request frame should be a data rate defined in the basic data rate set.

The Indication Multicast Address field configured in the Location Indication Parameters subelement shall be a multicast locally administered IEEE MAC address as defined in IEEE Std 802 that is shared across all APs in the same ESS. The STA shall transmit Location Track Notification frames to the Indication Multicast Address with the BSSID field set to the wildcard BSSID. An AP shall discard Location Track Notification frames that are not addressed to the Indication Multicast Address field configured for the ESS.

A non-AP STA shall terminate the transmission of Location Track Notification frames for any of the following reasons:

- The non-AP STA receives a Location Configuration Request frame from the STA to which it is currently associated that includes a Location Parameters element with a Location Indication Parameters subelement specifying an interval of 0.
- The non-AP STA fails to detect any Beacon frames, belonging to the same ESS that originally configured the non-AP STA, for the period specified by the essDetectionInterval value included in the Location Parameters element transmitted in the Location Configuration Request frame.
- dot11LocationTrackingActivated is false.
- The non-AP STA is disassociated for any reason from the ESS that configured it, including power off, or is configured by a different ESS.
- In an IBSS when the STA detects that it is no longer connected to the other STA that formed the IBSS.

NOTE—All Public Action frames, including the Location Track Notification frames, are Class 1 frames and the treatment of Public Action frames upon reception by STAs is defined in 11.3.

11.24.4.2 Location track notification procedures

Implementation of location track notification is optional for a WNM STA. A STA that implements location track notification has `dot11LocationTrackingImplemented` equal to true. When `dot11LocationTrackingImplemented` is true, `dot11WirelessManagementImplemented` shall be true. A STA in which `dot11LocationTrackingActivated` is true is defined as a STA that supports location track notification. When location track notification is supported, a STA configured by another STA as described in the previous subclause shall transmit Location Track Notification frames as shown in the informative diagram in Figure 11-32.

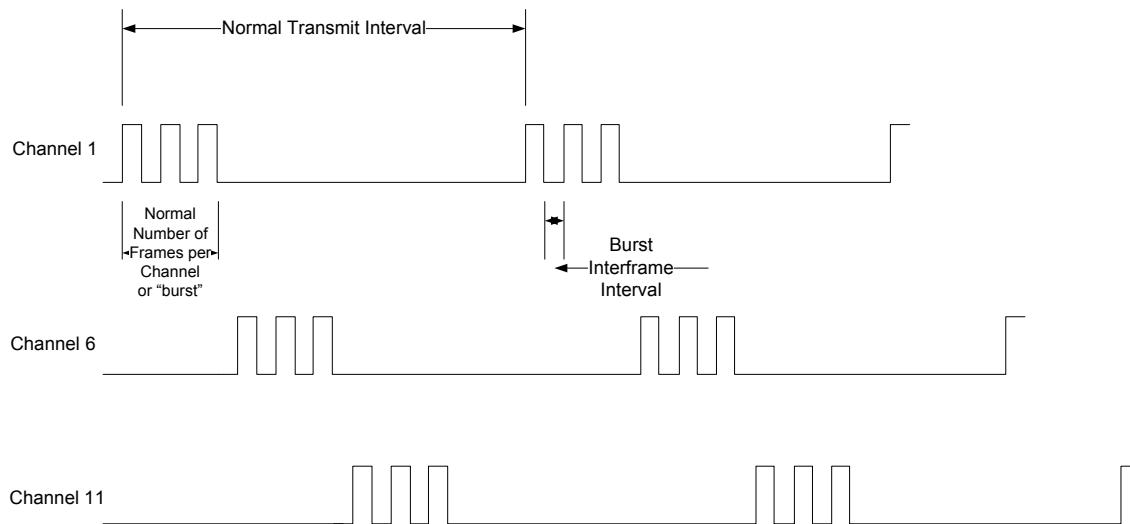

Figure 11-32—STA transmission on three channels, three frames per channel with Normal Report Interval

Implementation of Motion Detection or the Time of Departure reporting is optional for a WNM STA. A STA that implements motion detection shall set `dot11MotionDetectionImplemented` to true. When `dot11MotionDetectionImplemented` is true, `dot11WirelessManagementImplemented` shall be true. A STA whose `dot11MotionDetectionActivated` is true shall support motion detection. A STA that implements the time of departure capability shall set its `dot11TODImplemented` to true. When `dot11TODImplemented` is true, `dot11WirelessManagementImplemented` shall be true. A STA whose `dot11TODActivated` is true shall support time of departure for location tracking.

The STA transmits Location Track Notification frames based on the following parameters and procedures described in 11.24.4.1:

- Location Indication Channels. This subelement indicates the channels on which the STA shall transmit Location Track Notification frames.
- Indication Multicast Address
 - A non-IBSS STA shall transmit the Location Track Notification frames to the Indication Multicast Address field in the Location Indication Parameters subelement configured by the Location Configuration Request frame.
 - An AP shall discard any Location Track Notification frame received from a STA that does not match the Indication Multicast Address field value for the AP's ESS.

- 3) An IBSS STA shall transmit the Location Track Notification frames to the destination address of the STA that configured the STA using Location Configuration Request frames.
- c) Location Indication Interval
 - 1) When the STA is stationary or dot11MotionDetectionActivated is false, the STA shall transmit a sequence of groups of Location Track Notification frames on each channel. Each group of frames shall contain Normal Number of Frames Per Channel field frames. The first frame in each group of Location Track Notification frames shall be separated from the first frame in the previous group of Location Track Notification frames by a minimum time duration indicated by the value of the Normal Report Interval field times the value of the Normal Report Interval Units field.
 - 2) When the STA is in motion and dot11MotionDetectionActivated is true, the STA shall transmit a sequence of groups of Location Track Notification frames on each channel. Each group of frames shall contain In-Motion Number of Frames Per Channel field frames. The first frame in each group of Location Track Notification frames shall be separated from the first frame in the previous group of Location Track Notification frames by a minimum time duration indicated by the value of the In-Motion Report Interval times the value of the In-Motion Report Interval Units field.
 - 3) If a STA is configured to transmit on multiple channels, the STA shall transmit the frames on a single channel before continuing onto the next channel in the configured list of channels.
 - 4) All Location Track Notification frames transmitted on a single channel shall be transmitted with a minimum gap specified by the Burst Interframe Interval field.
 - 5) A STA can never be stationary and in-motion at the same time, and therefore only the Normal Interval field or the In-Motion Interval field apply at any given moment.
- d) Tracking Duration
 - 1) The STA shall transmit Location Track Notification frames until the Tracking Duration duration is reached.
 - 2) The duration starts as soon as the STA sends a Configuration Location Response frame with a Location Status value of Success.
 - 3) If the Tracking Duration is a nonzero value the STA shall transmit Location Track Notification frames, based on the Normal and In-Motion Report Interval field values, until the duration ends or is configured to terminate transmission as described in 11.24.4.1.
 - 4) If the Tracking Duration is 0 the STA shall continuously transmit Location Track Notification frames as defined by Normal and In-Motion Report Interval field values until configured to terminate transmission as described 11.24.4.1.
- e) ESS Detection
 - 1) The ESS Detection Interval field is specified in the Location Indication Parameters subelement configured by the Location Configuration Request frame. The ESS Detection Interval defines how often the STA should check for beacons transmitted by one or more APs belonging to the same ESS that configured the STA.
 - 2) If no beacons from the ESS are received during this interval, the STA shall terminate transmission of Location Track Notification frames.
- f) Location Indication Options
 - 1) The RM Enabled Capabilities element contained in (Re)Association Request frames indicates the STA's ability to perform radio measurements as described in 9.4.2.45. The Location Indication Options subelement Options Used field Beacon Measurement Mode Used bit shall be set to 0 by the AP when the RM Enabled Capabilities element bits (defined in Table 9-157), Beacon Passive Measurement Capability Enabled, Beacon Active Measurement Capability Enabled and Beacon Table Measurement Capability Enabled are all set to 0. If any of RM Enabled Capabilities element bits Beacon Passive Measurement capability enabled, Beacon Active Measurement Capability Enabled or Beacon Table Measurement Capability Enabled are

equal to 1 then the Location Indication Options subelement Options Used field Beacon Measurement Mode Used bit may be set to 1.

- 2) If the Location Indication Options subelement is included and the Options Used field with the Beacon Measurement Mode Used bit equal to 1 in the most recently received Location Configuration Request frame, the STA shall include in the Location Track Notification frames, the result of the most recent successful beacon measurement that was performed using the requested Beacon Measurement Mode contained in the Location Indications Options subelement.
 - 3) If the STA has never performed a successful beacon measurement using the requested Beacon Measurement Mode prior to transmission of the Location Track Notification frame, the STA shall perform the beacon measurement using the requested Beacon Measurement Mode and include the results of that measurement in Location Track Notification frames.
 - 4) After a successful Location Configuration Request frame that included the Location Indication Options subelement and Options Used field with Beacon Measurement Mode Used bit equal to 1, a STA should continue to perform beacon measurement as defined by the Beacon Measurement Mode periodically. How often and under what circumstances the STA performs this measurement is out of scope of this standard.
 - 5) Whenever a STA includes the beacon measurement in the Location Track Notification frames, the STA shall set the Measurement Token field in the Measurement Report element to the same value as the Dialog Token field in the Location Configuration Request frame that initiated the transmission of the location track notification frames by the STA.
 - 6) If the Location Indication Options subelement is not included in the most recently received Location Configuration Request frame or the Location Indication Options subelement is included with the Options Used field with Beacon Measurement Mode Used bit equal to 0, the STA shall not include any beacon measurements in the Location Track Notification frame
- g) Location Indication Broadcast Data Rate. The STA shall transmit Location Track Notification frames at the data rate specified in this subelement.
- h) Time of Departure
- 1) If dot11TODActivated is true, the STA shall transmit this subelement in the Location Track Notification frame.
 - 2) In all location tracking frames transmitted by a STA following a successful configuration, the Time of Departure subelement TOD Clock Rate field shall be set to the same value.
 - 3) If the STA has multiple antennas, it shall transmit using an approximation to an omnidirectional pattern.

NOTE—The values of the fields in the Time of Departure subelement are measured by the PHY in real time, then passed without real-time requirements to the MAC via the TXSTATUS parameter of the PHY-TXSTART.confirm primitive.

The diagram in Figure 11-32 shows an example of Location Track Notification frame transmission, for a STA configured to transmit on three channels, with three frames per channel. In this example, a Normal Transmit Interval and Normal number of frames per channel are shown. When a STA is capable of motion detection and is in motion, the In-Motion Report Interval and In-Motion number of frames per channel would apply.

11.24.5 Timing measurement procedure

Implementation of timing measurement is optional for a WNM STA. A STA in which dot11TimingMsmtActivated is true is defined as a STA that supports timing measurement.

A STA in which dot11TimingMsmtActivated is true shall set the Timing Measurement field of the Extended Capabilities element to 1.

A STA in which dot11TimingMsmtActivated is false shall set the Timing Measurement field of the Extended Capabilities element to 0.

A STA that supports the timing measurement procedure may transmit a Timing Measurement Request frame to a peer STA to request it to initiate or to stop an ongoing timing measurement procedure, depending on the value of the Trigger field in the request frame. See Figure 11-33.

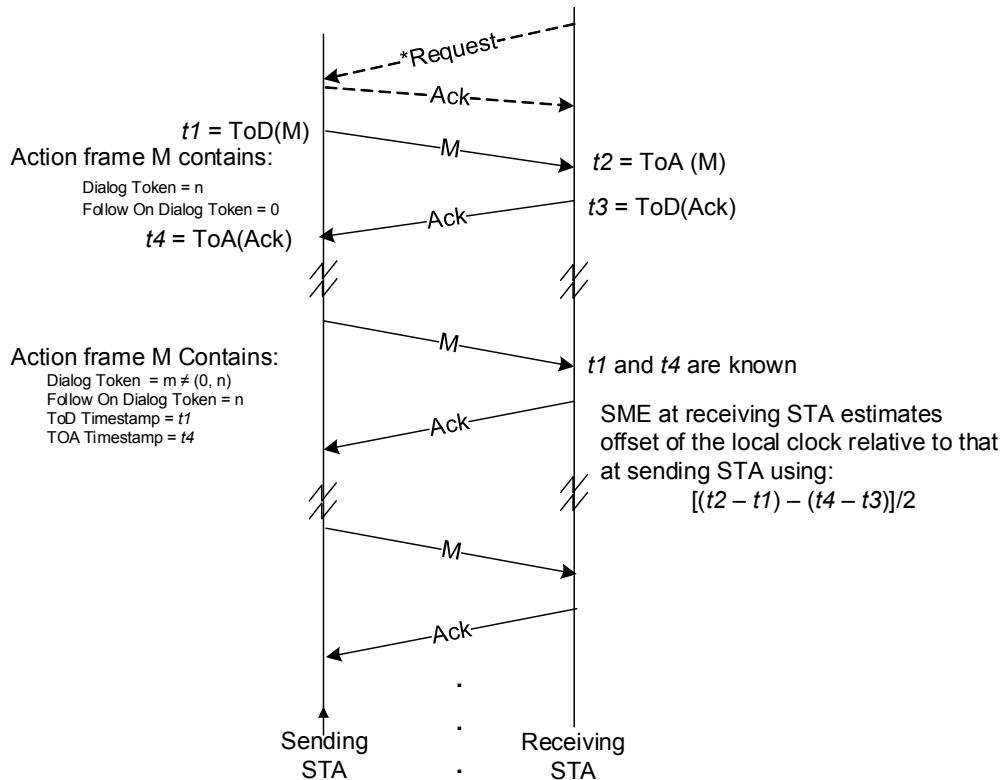

Figure 11-33—Timing measurement procedure

A STA that supports the timing measurement procedure may transmit Timing Measurement frames addressed to a peer STA that also supports the timing measurement procedure. One higher-layer protocol for synchronizing a local clock time between STAs using this feature is specified in IEEE Std 802.1AS.

For non-DMG STAs, both the Timing Measurement frame and the corresponding Ack frame shall be transmitted using a single transmit chain.

A sending STA transmits Timing Measurement frames in overlapping pairs. The first Timing Measurement frame of a pair contains a nonzero value in the Dialog Token field. The follow up Timing Measurement frame contains a Follow Up Dialog Token field set the value of the Dialog Token field in the first frame of the pair. With the first Timing Measurement frame, both STAs capture timestamps. The sending STA captures the time at which the Timing Measurement frame is transmitted ($t1$). The receiving STA captures the time at which the Timing Measurement frame arrives ($t2$) and the time at which the Ack frame response is transmitted ($t3$). The sending STA captures the time at which the Ack frame arrives ($t4$). See Figure 6-16 in 6.3.57. In the follow up Timing Measurement frame, the sending STA transfers the timestamp values it captured ($t1$ and $t4$) to the receiving STA.

NOTE—A Timing Measurement frame can contain nonzero values in both the Dialog Token and Follow Up Dialog Token fields, meaning that the Action frame contains follow up information from a previous measurement, and new Timestamp values are captured to be sent in a future follow up Timing Measurement frame.

The offset of the clock at the receiving STA with respect to the clock at the sending STA is calculated using Equation (11-4) (assuming a symmetric wireless channel). See Figure 6-16 in 6.3.57.

$$\text{Clock offset at receiving STA relative to sending STA} = [(t_2 - t_1) - (t_4 - t_3)]/2 \quad (11-4)$$

NOTE—An example of state machines and other computations for synchronizing a local clock time between IEEE 802.11 STAs using the values of t_1 , t_2 , t_3 , and t_4 provided by the Timing Measurement feature is found in Clause 12 of IEEE Std 802.1AS.

The acknowledgment procedure for Timing Measurement frames is the same as that for other Management frames (see 10.3.2.9). If the Ack frame for a transmitted Timing Measurement frame is not received, the sending STA may retransmit the frame. The sending STA shall capture a new set of timestamps for the retransmitted frame and its Ack frame.

On receiving a Timing Measurement frame with a Dialog Token for which timestamps have previously been captured, the receiving STA shall discard previously captured timestamps and capture a new set of timestamps.

11.24.6 Fine timing measurement (FTM) procedure

11.24.6.1 Overview

The FTM procedure allows a STA to determine its distance from another STA. In order for a STA to obtain its location, the STA may perform this procedure with multiple STAs whose locations are known.

An FTM session is an instance of a FTM procedure between an initiating STA and a responding STA along with the associated scheduling and operational parameters of that instance (see 9.4.2.168). An FTM session is composed of a negotiation, measurement exchange and termination. A STA might have multiple concurrent FTM sessions. Concurrent FTM sessions might occur with responding STAs that are members of different BSSs and possibly different ESSs, or possibly outside of a BSS, each session using its own scheduling, channel and operational parameters.

A responding STA might be required to establish overlapping FTM sessions with a large number of initiating STAs (e.g., an AP providing measurements to STAs at a mall or a store). On the other hand, an initiating STA might have multiple ongoing FTM sessions on the same or different channels with different responding STAs, while being associated with an AP for the exchange of data or signaling.

To support the constraints of both the initiating and responding STAs, during the negotiation phase the initiating STA initially requests a preferred periodic time window allocation. The responding STA subsequently responds by accepting or overriding the allocation request based on its resource availability and capability.

Since some of the initiating STA's activities may be nondeterministic and might have higher precedence than the FTM session (e.g., data transfer interaction with an associated AP), a conflict might prevent the initiating STA from being available at the beginning of the burst instance determined by the responding STA.

Figure 11-34 shows an example of such scheduling conflicts.

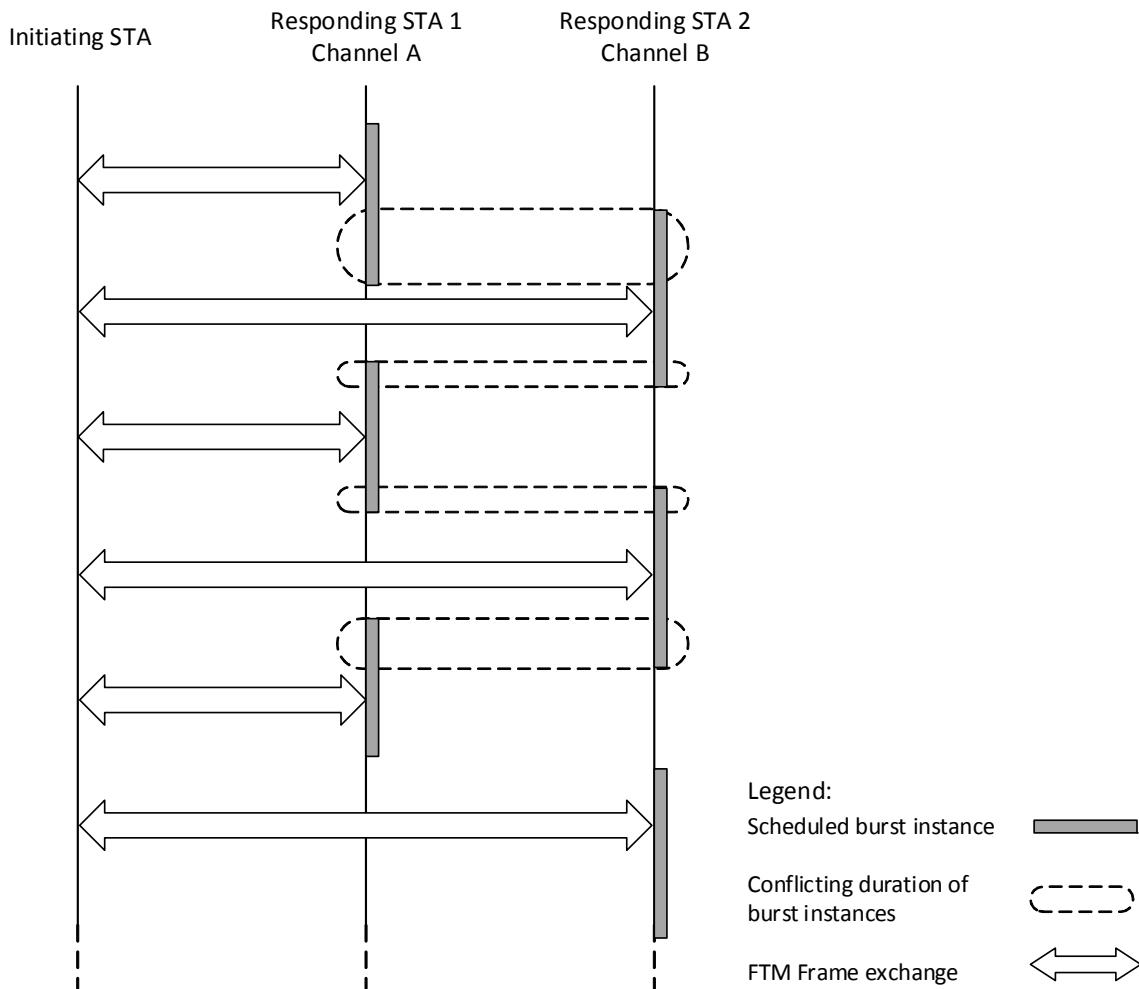

Figure 11-34—Concurrent FTM sessions

The initiating STA in Figure 11-34 establishes sessions with responding STA 1 and responding STA 2 on different channels. The sessions' burst instance periodicity might be different as well as the STAs' clock offsets and thus, over time, some temporal conflicts may occur. To overcome this, during each burst instance the initiating STA indicates its availability by transmitting a Fine Timing Measurement Request frame (see 11.24.6.4). During each burst instance, the responding STA transmits one or more Fine Timing Measurement frames as negotiated.

11.24.6.2 FTM capabilities

Implementation of FTM is optional for a WNM STA. A STA in which `dot11FineTimingMsmtRespActivated` is true is defined as a STA that supports FTM as a responder. A STA in which `dot11FineTimingMsmtInitActivated` is true is defined as a STA that supports FTM as an initiator.

When `dot11FineTimingMsmtRespActivated` is true, `dot11WirelessManagementImplemented` shall be true. When `dot11FineTimingMsmtInitActivated` is true, `dot11WirelessManagementImplemented` shall be true.

A STA in which `dot11FineTimingMsmtRespActivated` is true shall set the Fine Timing Measurement Responder field of the Extended Capabilities element to 1.

A STA in which dot11FineTimingMsmtInitActivated is true shall set the Fine Timing Measurement Initiator field of the Extended Capabilities element to 1.

A STA in which dot11FineTimingMsmtRespActivated is false shall set the Fine Timing Measurement Responder field of the Extended Capabilities element to 0.

A STA in which dot11FineTimingMsmtInitActivated is false shall set the Fine Timing Measurement Initiator field of the Extended Capabilities element to 0.

11.24.6.3 Fine timing measurement procedure negotiation

In order to initiate a FTM procedure, a STA that supports the FTM procedure as an initiator (referred to as an *initiating STA*) shall transmit a Fine Timing Measurement Request frame. This frame is called the *initial* Fine Timing Measurement Request frame. After transmission of this frame, the initiating STA shall be ready to receive a Fine Timing Measurement frame.

A STA that supports the FTM procedure as a responder (referred to as a *responding STA*) shall not transmit Fine Timing Measurement frames addressed to a peer STA unless the responding STA has received an initial Fine Timing Measurement Request frame from the peer STA.

The initial Fine Timing Measurement Request frame shall have:

- the Trigger field set to 1,
- a set of scheduling parameters in a Fine Timing Measurement Parameters element that describe the initiating STA's availability for measurement exchange.

The first Fine Timing Measurement frame in the FTM session is called the *initial* Fine Timing Measurement frame. The responding STA should transmit an initial Fine Timing Measurement frame within 10 ms in response to the initial Fine Timing Measurement Request frame. This initial Fine Timing Measurement frame shall include the Fine Timing Measurement Parameters element. The value of the Status Indication field indicates the outcome of the request.

NOTE—In an initial Fine Timing Measurement frame, the responding STA might indicate that the request for an FTM session is successful, even if the initial Fine Timing Measurement frame includes at least one of

- A Measurement Report element that indicates an unknown LCI or
- A Measurement Report element that indicates an unknown civic location.

In the case of requests for 160 MHz bandwidth, the initiating STA shall indicate in the Format And Bandwidth field whether it uses a single or two separate RF LOs. In the cases when the responding STA indicates use of 160 MHz bandwidth, the responding STA shall indicate in the Format And Bandwidth field whether it uses a single or two separate RF LOs.

The initiating STA shall indicate, in the Format and Bandwidth field, a format and bandwidth that it supports. The responding STA shall indicate, in the Format and Bandwidth field, a format and bandwidth that it supports. The responding STA should indicate the same format and bandwidth in the Format and Bandwidth field as that requested by the initiating STA, if the responding STA supports this. The responding STA shall not indicate a bandwidth wider than requested. The responding STA shall not indicate a VHT format if DMG, HT-mixed or non-HT format was requested. The responding STA shall not indicate an HT format if DMG or non-HT format was requested. The responding STA shall not indicate a DMG format if VHT, HT-mixed or non-HT format was requested.

If the request was successful

- The initiating STA shall indicate, in the Format and Bandwidth field, a format and bandwidth it supports. The responding STA shall indicate, in the Format and Bandwidth field, a format and

bandwidth that it supports. The responding STA should indicate the same format and bandwidth in the Format and Bandwidth field as that requested by the initiating STA, if the responding STA supports this. The responding STA shall not indicate a bandwidth wider than requested. The responding STA shall not indicate a VHT format if DMG, HT-mixed or non-HT format was requested. The responding STA shall not indicate a DMG format if VHT, HT-mixed or non-HT format was requested.

- An initiating STA performing a FTM procedure with a responding STA that is an AP shall support non-ASAP operation.
- A responding STA that is an AP shall support and select non-ASAP operation when so requested by an initiating STA.
- An initiating STA performing a FTM procedure with a responding STA that is not an AP shall support ASAP operation.
- A responding STA that is not an AP shall support and select ASAP operation when so requested by an initiating STA.
- If the responding STA is ASAP capable, the responding STA’s selection of ASAP should be the same as that requested by the initiating STA.
- The responding STA’s selection of the Min Delta FTM field value shall be greater than or equal to the value requested by the initiating STA.
- The responding STA’s selection of the Number of Bursts Exponent field value shall be 0 if the initiating STA requested it to be 0.
- The responding STA’s selection of the Burst Duration field value should be less than or equal to the one requested by the initiating STA if the requested FTMs per Burst field value is set to a value indicating no preference, subject the recommendations below and the responding STA’s policy on the maximum and minimum Burst Duration field values.
 - If the Number of Bursts Exponent field is set to 0 and the ASAP field is set to 1, the Burst Duration field value should be set to indicate the value BD_1 , defined as follows:

$$BD_1 = ((N_{FTMPB} \times (K + 1)) - 1) \times T_{MDFTM} + T_{FTM} + aSIFSTime + T_{Ack}$$

where

N_{FTMPB} is the value of the FTMs per Burst field

K is the maximum number of Fine Timing Measurement frame retransmissions the responding STA might attempt

T_{MDFTM} is the duration indicated by the Min Delta FTM field of the Fine Timing Measurement Parameters field of the initial Fine Timing Measurement frame (FTM_1)

T_{FTM} is the duration of the initial Fine Timing Measurement frame if the FTMs per Burst field of the Fine Timing Measurement Parameters field of FTM_1 is set to 1, and the duration of the non initial Fine Timing Measurement frame otherwise

T_{Ack} is the duration of the Ack frame expected as a response

- Otherwise, the Burst Duration field value should be set to indicate a value greater than or equal to the following value:

$$BD_1 + T_{FTMR} + aSIFSTime + T_{Ack} + T_{ACCESS_FTM}$$

where

T_{FTMR} is the duration of a Fine Timing Measurement Request frame without a Measurement Request element and without a Fine Timing Measurement Parameters element

T_{ACCESS_FTM} is the estimated medium access time for the first FTM frame in a burst

- The responding STA's selection of the value of the FTMs per Burst field should be the same as the one requested by the initiating STA if the requested value of the Burst Duration field is set to a value indicating no preference (see Table 9-257), subject to the responding STA's policy on the maximum value of the FTMs per Burst field.
- The responding STA's selection of Burst Period shall be greater than or equal the responding STA's selection of Burst Duration.

NOTE—Apart from the Status Indication, Value, ASAP, Number of Bursts Exponent, Min Delta FTM, and Burst Period fields, the other fields in the Fine Timing Measurement Parameters element in the initial Fine Timing Measurement frame have no constraints.

When the responding STA cannot support the initiator's Min Delta FTM or Number of Bursts Exponent constraints, the responding STA shall set the Status Indication field to Request incapable and the FTM session ends. When the responding STA is unable to fulfill the request by the initiating STA, the responding STA shall set the Status Indication field to Request failed and the FTM session ends.

11.24.6.4 Measurement exchange

Fine Timing Measurement frames are sent during time windows called *burst instances*. The timing of the burst instances is defined by the following parameters:

- Partial TSF Timer – The partial TSF timer, as defined in 9.4.2.168, at the beginning of the first burst instance
- Burst Duration – The duration of each burst instance starting at the boundary of a burst period
- Burst Period – The interval from the beginning of one burst instance to the beginning of the following burst instance.

The initiating STA shall transmit a Fine Timing Measurement Request frame without a Measurement Request element, without a Fine Timing Measurement Parameters element and with the Trigger field set to 1 as soon as it is available on channel during a burst instance. This indicates to the responding STA its availability for the remainder of the burst instance. In response, the responding STA shall transmit an Ack frame and should transmit FTMs per Burst Fine Timing Measurement frames before the end of the burst instance. In addition, the initiating STA shall be ready to receive a Fine Timing Measurement frame. The first Fine Timing Measurement frame and its retransmissions in the burst instance from the responding STA shall include an FTM Synchronization Information element in the FTM Synchronization Information field. The TSF Sync Info field in the FTM Synchronization Information element contained in the Fine Timing Measurement frame might be used by the initiating STA to synchronize its TSF with the responding STA's in order to determine the start of subsequent burst instances. Subsequent Fine Timing Measurement frames within the burst instance shall not include a Fine Timing Measurement Parameters element and shall not include an FTM Synchronization Information field (for additional constraints on the Fine Timing Measurement frame see 11.24.6.7). Consecutive Fine Timing Measurement frames to a given peer STA shall be spaced at least Min Delta FTM apart. Within a burst instance the initiating STA shall perform FTM on each Fine Timing Measurement frame addressed to it, except the last Fine Timing Measurement frame. The initiating STA may perform FTM on the last Fine Timing Measurement frame in a burst instance.

NOTE—If the initiating STA successfully transmits a non-initial Fine Timing Measurement Request frame late in a burst instance, fewer than FTMs per burst might be successfully transmitted by the responding STA in the burst instance. If a Fine Timing Measurement frame, except for the initial Fine Timing Measurement frame in the ASAP=0 case, is sent outside a burst instance, it might not be acknowledged.

The first burst instance shall start at the value indicated by the value of the Partial TSF Timer field in the initial Fine Timing Measurement frame, regardless of the ASAP field's value. When ASAP is set to 1 by the responding STA, the Partial TSF Timer field value shall be set to a value less than 10 ms from the reception of the most recent initial Fine Timing Request frame.

The scheduling parameters of an FTM session are illustrated in Figure 11-35.

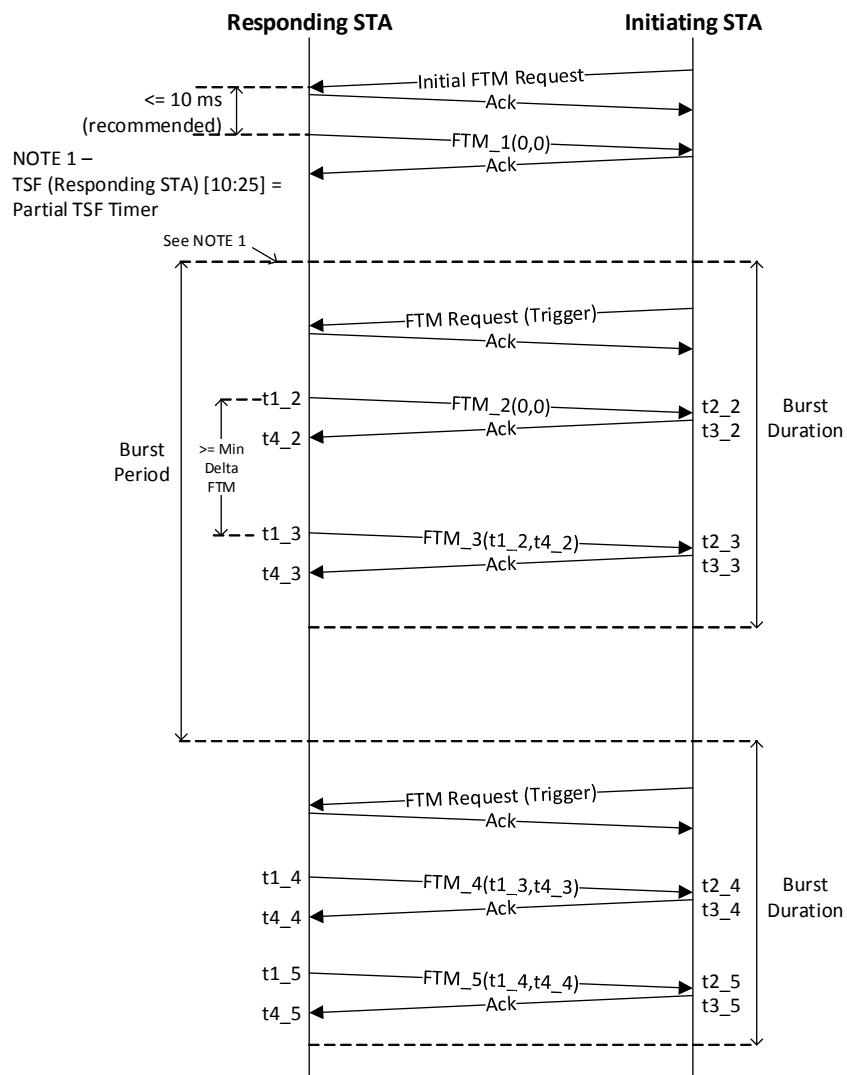

Figure 11-35—Example negotiation and measurement exchange sequence, ASAP=0, and FTM_s per Burst = 2

The initiating STA can request the responding STA to start the burst instances “as soon as possible” by setting the ASAP field to 1. The scheduling in this case is illustrated in Figure 11-36.

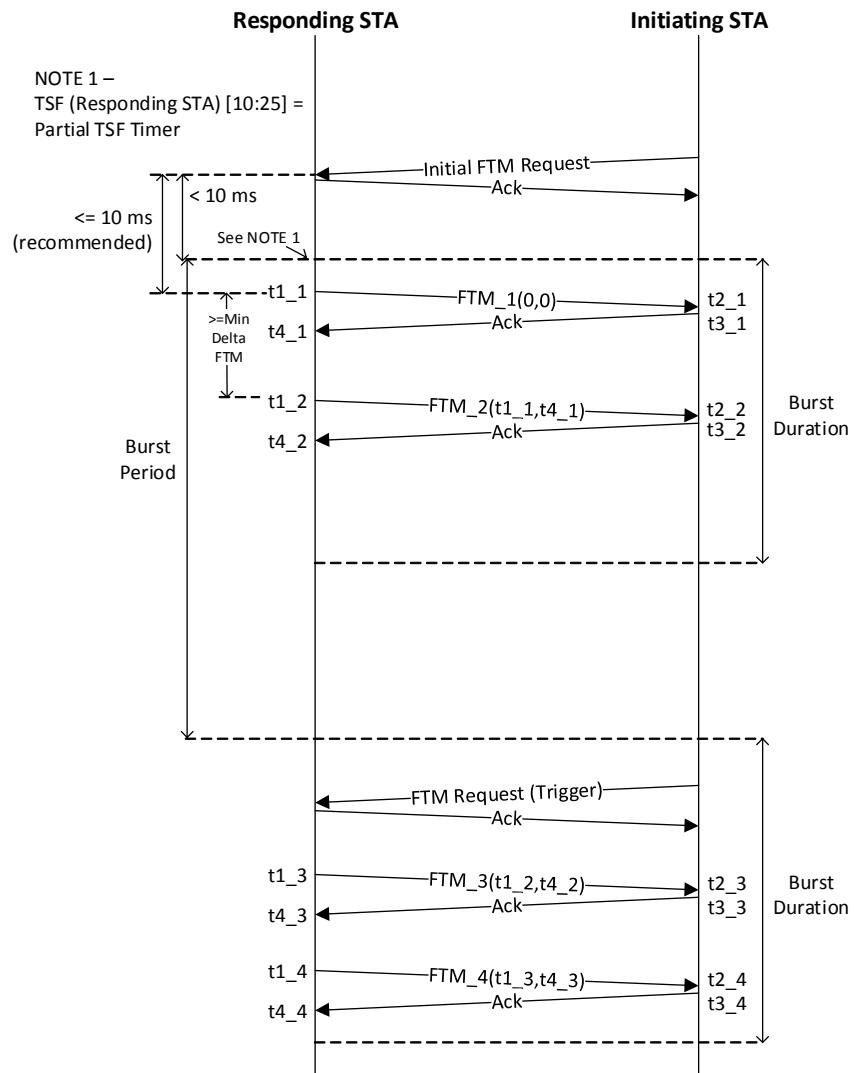

Figure 11-36—Example negotiation and measurement exchange sequence, ASAP=1, and FTMs per Burst = 2

The initiating STA may also request a single burst of FTM to be taken as soon as possible, in which case it sets the Number of Bursts Exponent field to 0 and the ASAP field to 1. This is illustrated in Figure 11-37.

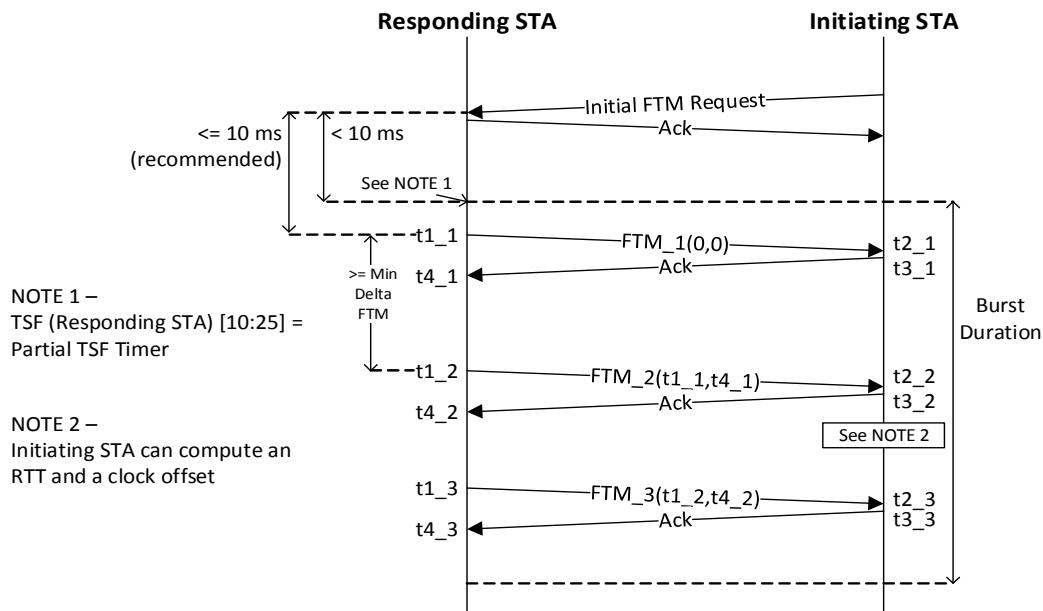

Figure 11-37—Example negotiation and measurement exchange sequence for a single burst instance, ASAP=1, and FTM per Burst = 3

For non-DMG STAs, both the Fine Timing Measurement frame and the corresponding Ack frame shall be transmitted using a single transmit chain.

The responding STA shall not transmit Fine Timing Measurement frames using Clause 15 or Clause 16 formats, MCS 32 format, or HT-greenfield format.

The responding STA should transmit Fine Timing Measurement frames with the format and bandwidth it indicated.

For the Fine Timing Measurement frames transmitted during the FTM session:

- The responding STA shall not use a bandwidth wider than that indicated by the STA in the initial Fine Timing Measurement frame.
- The responding STA shall not use a VHT format if the STA indicated HT-mixed or non-HT format in the initial Fine Timing Measurement frame.
- The responding STA shall not use an HT format if the STA indicated non-HT format in the initial Fine Timing Measurement frame.

The ASAP Capable field shall be set to 1 in the initial Fine Timing Measurement frame if a responding STA is ASAP-capable; otherwise it shall be set to 0.

A responding STA transmits Fine Timing Measurement frames in overlapping pairs of consecutive frames. For example, in Figure 11-36, FTM_1 and FTM_2, FTM_2 and FTM_3, and FTM_3 and FTM_4 are overlapping pairs of consecutive frames. The first Fine Timing Measurement frame of a pair of consecutive Fine Timing Measurement frames contains a nonzero value in the Dialog Token field. The follow up Fine Timing Measurement frame contains a Follow Up Dialog Token field set to the value of the Dialog Token field in the first frame of the consecutive pair. Dialog Token field values of consecutive Fine Timing

Measurement frames shall be consecutive, except when the value wraps around to 1 or in the last Fine Timing Measurement frame in an FTM session. With the first Fine Timing Measurement frame, both STAs capture timestamps. The responding STA captures the time at which the Fine Timing Measurement frame is transmitted ($t1$). The initiating STA captures the time at which the Fine Timing Measurement frame arrives ($t2$) and the time at which the Ack response is transmitted ($t3$). The responding STA captures the time at which the Ack frame arrives ($t4$). See Figure 6-17. In the follow up Fine Timing Measurement frame, in the same or the subsequent burst, the responding STA transfers the timestamp values it captured ($t1$ and $t4$) to the initiating STA. In this follow up Fine Timing Measurement frame, the timestamp values ($t1$ and $t4$) shall be the measurement according to the responding STA’s clock (i.e., without applying any frequency offset correction to the time bases).

NOTE—A Fine Timing Measurement frame can contain nonzero values in both the Dialog Token and Follow Up Dialog Token fields, meaning that the Action frame contains follow up information from a previous measurement, and new Timestamp values are captured to be sent in a future follow up Fine Timing Measurement frame.

When the ASAP field is set to 0 by a responding STA, the Follow Up Dialog Token, TOD, TOA, TOD Error, and TOA Error fields in the Fine Timing Measurement frame following the initial Fine Timing Measurement frame shall be reserved.

When the ASAP field is set to 1 by a responding STA, the timestamps for the initial Fine Timing Measurement frame shall be captured and sent in the following Fine Timing Measurement frame. In the Fine Timing Measurement frame following the initial Fine Timing Measurement frame, the TOD and TOA fields shall be set to the timestamps associated with the initial Fine Timing Measurement frame.

The round trip time (RTT) is defined by Equation (11-5).

$$RTT = [(t4' - t1') - (t3 - t2)] \quad (11-5)$$

where $t1'$ and $t4'$ are the time at which the Fine Timing Measurement frame was transmitted and the time at which the Ack was received, respectively, as determined by the initiating STA.

At the initiating STA, the mechanism by which $t1'$ and $t4'$ are derived from the TOD and TOA fields is implementation dependent.

The Fine Timing Measurement protocol can also be used to synchronize a local clock between STAs. One higher-layer protocol for synchronizing a local clock time between STAs is specified in IEEE Std 802.1AS.

The SME at the initiating STA may estimate the offset of the local clock relative to that at the responding STA using clock offset as defined by Equation (11-6).

$$\text{clock offset} = [(t2 - t1') - (t4' - t3)]/2 \quad (11-6)$$

NOTE—The initiating STA might track this clock offset over time to derive an estimate of the difference between the initiating STA’s time base and the responding STA’s time base, and thereby improve the accuracy of its derivation of $t1'$ and $t4'$ from the TOD and TOA fields.

If the Ack frame for a transmitted Fine Timing Measurement frame is not received, the responding STA shall not retry the frame. In order to send the frame again, the responding STA shall send a Fine Timing Measurement frame with the same Action frame body as the Fine Timing Measurement frame for which the Ack was not received, except for updating the Dialog Token if it was nonzero. The Sequence Number in the MAC header is also updated. This is called an *FTM retransmission*.

A responding STA that transmits a Fine Timing Measurement frame with the ASAP field set to 0 shall set the Partial TSF Timer field to an offset value D_{TSF} from the partial value of the responding STA’s TSF timer at the time of the transmission of the Ack to the last Fine Timing Measurement Request frame from the initiating STA, subject to

$$D_{TSF} \geq K_I \times T_{MDFTM_I} + T_{FTM_I} + aSIFSTime + T_{Ack} + T_{ACCESS_FTM1}$$

where

| | |
|--------------------|--|
| K_I | is the maximum number of initial Fine Timing Measurement frame (FTM_1) retransmissions the responding STA might attempt. |
| T_{MDFTM} | is the value of the Min Delta FTM field of the Fine Timing Measurement Parameters field of FTM_1. |
| T_{FTM_I} | is the duration of the FTM_1. |
| T_{Ack} | is the duration of the Ack frame expected as a response. |
| T_{ACCESS_FTM1} | is the estimated medium access time for FTM_1. |

NOTE—This value of the Partial TSF Timer field ought to result in the Fine Timing Measurement Request frame not being transmitted before a successful transmission of FTM_1.

When neither an Ack to the initial Fine Timing Measurement frame nor a Fine Timing Measurement Request frame has been received by the responding STA, the responding STA shall not terminate the FTM session before the time indicated by the Partial TSF timer plus the Burst Duration.

The responding STA shall set the Follow Up Dialog Token field to 0 in the initial Fine Timing Measurement frame and its FTM retransmissions.

The responding STA shall set the Dialog Token field to 0 in the last Fine Timing Measurement frame and its FTM retransmissions.

11.24.6.5 Fine timing measurement parameter modification

During an FTM session, an initiating STA may terminate the current session and request a new session with modified session parameters by transmitting a Fine Timing Measurement Request frame with Trigger field set to 1 and including a new Fine Timing Measurement Parameters element. The existing FTM session is terminated upon reception of such a Fine Timing Measurement Request frame. This Fine Timing Measurement Request frame is an initial Fine Timing Measurement Request frame for the new FTM session, which follows the behavior described in 11.24.6.3.

11.24.6.6 Fine timing measurement termination

An FTM session terminates after the last burst instance, as indicated in the Number of Bursts Exponent, Burst Duration, FTMs per Burst and Burst Period fields in the initial Fine Timing Measurement frame.

An FTM session may be terminated before then through one of the following:

- At any time during the FTM session when the responding STA is permitted to transmit a Fine Timing Measurement frame (see 11.24.6.4), the responding STA sends a Fine Timing Measurement frame with the Dialog Token field set to 0.
- At any time during the FTM session when the initiating STA is permitted to transmit a Fine Timing Measurement frame (see 11.24.6.4), the initiating STA sends a Fine Timing Measurement Request frame with the Trigger field set to 0. This frame shall not include:
 - a Measurement Request element
 - a Fine Timing Measurement Parameters element
- At any time during the FTM session when the initiating STA is permitted to transmit a Fine Timing Measurement frame (see 11.24.6.4), the initiating STA terminates the current session and requests a new session with modified Fine Timing Measurement parameters (see 11.24.6.5).

- After the number of burst instances indicated in the Number of Bursts Exponent field in the initial Fine Timing Measurement frame has been reached.

11.24.6.7 LCI and Location Civic retrieval using FTM procedure

Within the FTM procedure, a STA, to request the LCI of a responding STA that transmits an Extended Capabilities element with the Fine Timing Measurement Responder field set to 1, shall include a Measurement Request element with Measurement Type field equal to LCI within the Fine Timing Measurement Request frame.

Within the FTM procedure, a STA, to request the Location Civic of a responding STA that transmits an Extended Capabilities element with the Fine Timing Measurement Responder field set to 1, shall include a Measurement Request element with Measurement Type field equal to Location Civic within the Fine Timing Measurement Request frame.

A Measurement Request element with Measurement Type field equal to LCI shall not be included in a Fine Timing Measurement Request frame unless the Fine Timing Measurement Request frame also includes a Fine Timing Measurement Parameters element. A Measurement Request element with Measurement Type field equal to Location Civic shall not be included in a Fine Timing Measurement Request frame unless the Fine Timing Measurement Request frame also includes a Fine Timing Measurement Parameters element.

When a responding STA that has both dot11FineTimingMsmtRespActivated and dot11RMLCIConfigured equal to true receives a Measurement Request element with Measurement Type field equal to LCI within an initial Fine Timing Measurement Request frame, the responding STA shall include a Measurement Report element with Measurement Type field equal to LCI in the initial Fine Timing Measurement frame. If the maximum horizontal or vertical location error of the responding STA relative to a reference STA is known and this relative error is smaller than the absolute error indicated in the LCI subelement, then the responding STA may include a Relative Location Error subfield in the Measurement Report field. The responding STA shall not include a Measurement Report element with Measurement Type field equal to LCI in the Fine Timing Measurement frame in the current FTM session unless the responding STA's LCI has changed since the last time it was reported to the initiating STA.

When a responding STA that has at least one of dot11FineTimingMsmtRespActivated and dot11RMLCIConfigured equal to false receives a Measurement Request element with Measurement Type field equal to LCI within a Fine Timing Measurement Request frame, the responding STA shall include a Measurement Report element with the Incapable field set to 1 in the initial Fine Timing Measurement frame.

When a responding STA that has both dot11FineTimingMsmtRespActivated and dot11RMCCivicConfigured equal to true receives a Measurement Request element with Measurement Type field equal to Location Civic within an initial Fine Timing Measurement Request frame, the responding STA shall include a Measurement Report element with Measurement Type field equal to Location Civic in the initial Fine Timing Measurement frame. The responding STA shall not include a Measurement Report element with Measurement Type field equal to Location Civic in the Fine Timing Measurement frame in the current FTM session unless the responding STA's civic location has changed since the last time it was reported to the initiating STA.

When a responding STA that has at least one of dot11FineTimingMsmtRespActivated and dot11RMCCivicConfigured equal to false receives a Measurement Request element with Measurement Type field equal to Location Civic within a Fine Timing Measurement Request frame, the responding STA shall include a Measurement Report element with the Incapable field set to 1 in the initial Fine Timing Measurement frame.

Each Measurement Report element returned shall have the same Measurement Token value as in the Measurement Token field of the corresponding Measurement Request element. The Fine Timing

Measurement frame containing the Measurement Report element(s) should be returned without undue delay to the STA.

A STA that receives an LCI report that contains a Usage Rules/Policy subelement shall process the LCI information in compliance with the retransmission and retention permissions in the Usage Rules/Policy subelement.

11.24.7 BSS transition management for network load balancing

11.24.7.1 BSS transition capability

The BSS transition capability enables improved throughput, effective data rate and/or QoS for the aggregate of STAs in a network by shifting (via transition) individual STA traffic loads to more appropriate points of association within the ESS. In addition, the BSS transition capability provides accounting session control information to a non-AP STA, which might be used to provide an alert to the non-AP STA's user that the STA's session is almost over and the STA will be disassociated from the ESS.

The BSS Transition Management Query, BSS Transition Management Request, BSS Transition Management Response frames provide a means and a protocol to exchange the information needed to enable an AP to inform associated STAs that the BSS will be terminated and to enable a network to manage BSS loads by influencing STA transition decisions. A STA may provide neighbor report information to its associated AP for BSSs that it considers to be transition targets. This information enables the AP to request that the STA transition to a BSS that the STA also prefers.

Implementation of BSS transition management is optional for a WNM STA. A STA that implements BSS transition management has dot11BSSTransitionImplemented equal to true. When dot11BSSTransitionImplemented is true, dot11WirelessManagementImplemented shall be true. A STA whose dot11BSSTransitionActivated is true shall support BSS transition management and shall set to 1 the Transition field of the Extended Capabilities elements that it transmits.

The provisions in this clause for BSS transition management and network load balancing do not apply in an IBSS.

11.24.7.2 BSS transition management query

A non-AP STA supporting BSS transition management may request a BSS Transition Candidate list by sending a BSS Transition Management Query frame to its associated AP if the associated AP indicates that it supports the BSS Transition capability in the Extended Capabilities element. A non-AP STA should include the BSS Transition Candidate List Entries field in the BSS Transition Management Query frame to indicate the non-AP STA's transition preferences. If the non-AP STA transmits a BSS Transition Query frame only to provide transition preferences to the AP, then the BSS Transition Query Reason field of the BSS Transition Management Query frame shall be set to a value of 19, indicating "Preferred BSS Transition Candidate List Included."

The BSS Transition Candidate List Entries field of a BSS Transition Management Query frame contains zero or more Neighbor Report elements describing the non-AP STA's preferences for target BSS candidates. The Preference field value of a Neighbor Report element used in a BSS Transition Management Query frame shall be between 1 and 255. The value of 0 is reserved. The values between 1 and 255 provide the indication of order, with 255 indicating the most preferred BSS within the given candidate list, decreasing numbers representing decreasing preference relative only to entries with lower values of the Preference field, and equal numbers representing equal preference.

11.24.7.3 BSS transition management request

An AP that supports BSS transition management shall respond to a BSS Transition Management Query frame with a BSS Transition Management Request frame. The AP may send an unsolicited BSS Transition Management Request frame to a non-AP STA at any time if the non-AP STA indicates in the Extended Capabilities element that it support BSS transition management; otherwise the AP shall not send an unsolicited BSS Transition Management Request frame to the STA. The AP may transmit a group addressed BSS Transition Management Request frame to associated non-AP STAs if all associated non-AP STAs support the BSS transition management; otherwise the AP shall not transmit a group addressed BSS Transition Management Request frame. When the BSS Transition Management Request frame is transmitted as a group addressed frame, a receiving non-AP STA shall not respond with a BSS Transition Management Response frame. A non-AP STA that supports BSS transition management shall respond to an individually addressed BSS Transition Management Request frame with a BSS Transition Management Response frame.

The AP shall include the BSS Transition Candidate List Entries field in the BSS Transition Management Request frame if the AP has information in response to the BSS Transition Management Query frame. The BSS Transition Candidate List Entries field contains zero or more Neighbor Report elements describing the preferences for target BSS candidates. A Preference field value of 0 indicates that the BSS listed is an excluded BSS. The STA should refrain from associating to an AP corresponding to an excluded BSS. The Preference field values are used to establish the relative order of entries within the given list at the given time, and for the given AP.

The values between 1 and 255 provide the indication of order, with 255 indicating the most preferred BSS within the given candidate list, decreasing numbers representing decreasing preference relative only to entries with lower values of the Preference field, and equal numbers representing equal preference. The Preference field value is valid only before the validity interval has expired. The AP may include zero or more subelements in the BSS Transition Candidate List Entries field.

Upon reception of a BSS Transition Management Query frame or BSS Transition Response frame from a non-AP STA that contains a nonempty BSS Transition Candidate List Entries field, the AP should include at least one BSS candidate from that list with a nonzero Preference field value in the BSS Transition Candidate List Entries field of any subsequent BSS Transition Management Request frame with the Preferred Candidate List Included field set to 1 transmitted to the non-AP STA. The AP shall evaluate the BSSs indicated in the BSS Transition Candidate List Entries field in the latest BSS Transition Management Query frame or BSS Transition Management Response frame received from the non-AP STA as BSS transition candidate(s) for the non-AP STA. The means by which the AP evaluates and determines BSS transition candidates is outside the scope of this standard.

A STA that receives a BSS Transition Management Request frame with the Preferred Candidate List Included subfield of the Request Mode field equal to 0 may ignore the BSS Transition Candidate List Entries field of the frame.

A non-AP STA that receives the Abridged bit with a value of 1 shall treat any BSSID in the current ESS that does not appear in the BSS Transition Candidate List as if it were present in the BSS Transition Candidate List with a Preference value of 0.

The AP may include one BSS Termination Duration subelement for each BSS in the BSS Transition Candidate List Entry field, including the BSS Termination Duration value and a BSS Termination TSF value. The BSS Termination Duration value may be different for each BSS.

When the AP transmits a BSS Transition Management Request frame with the Disassociation Imminent field set to 1 to a non-AP STA, the Disassociation Timer field in the BSS Transition Management Request frame shall be set to 0 or set to the number of TBTTs that will occur prior to the AP disassociating the

non-AP STA. The AP shall start a timer for the non-AP STA with the initial timer value set to the Disassociation Timer field value. The AP shall decrement the timer by one after transmitting each Beacon frame until the timer has value of 0. In subsequent BSS Transition Management Request frames that the AP transmits to the non-AP STA, the Disassociation Timer field shall be set to the value of the timer.

If the most recent BSS Transition Management Request frame that an AP has transmitted to a non-AP STA has the Disassociation Imminent field set to 1, then the AP shall not transmit a Disassociation frame to the non-AP STA unless the timer for the non-AP STA has value of 0.

An AP's SME may have accounting session control information, such as a notice of session expiration. The means by which the AP's SME obtains accounting session control information is out of scope of this standard. Accounting session control information might include a time duration after which the non-AP STA will be disassociated from the ESS and an optional session information URL at which information may be obtained to extend the accounting session. When an AP's SME has accounting session control information, it shall issue an MLME-BTM.request primitive to the AP's MLME and shall encode the time to session expiration in the Disassociation Timer parameter and shall encode the URL, if available, in the SessionInformationURL parameter. A non-AP STA's SME that has received an MLME-BTM.indication primitive forwards the MLME-BTM.indication parameters to the appropriate entity within the device (e.g., web browser) to inform the end user; the means and protocol by which the SME accomplishes this is outside the scope of this standard.

A STA's SME receiving an MLME-BTM.indication primitive containing the BSS Transition Candidate List Entries field should use this list of candidates, with individual transition preference values, to make BSS transition decisions. Upon receiving an MLME-BTM.indication primitive, the STA's SME shall disregard any previous MLME-BTM.indication primitive received from the same AP. The STA shall not use the corresponding BSS Transition Candidate List Entries field information after the indicated validity interval. The STA may send a BSS Transition Management Query frame at any time to obtain an updated BSS Transition Candidate List Entries field or to indicate the STA's BSS transition candidates.

A STA's SME receiving an MLME-BTM.indication primitive containing a nonzero value of the Disassociation Timer field should attempt to find a suitable AP with which to reassociate before the indicated disassociation time.

11.24.7.4 BSS transition management response

When the STA's SME receives an MLME-BTM.indication primitive, it may issue an MLME-BTM.response primitive.

The STA's SME may include the result of its BSS transition decision in the Target BSSID field and BTM Status Code field in the MLME-BTM.response primitive. A BTM Status Code field set to a value of 0 (i.e., Accept) indicates the STA will transition from the current BSS. The STA's SME receiving an MLME-BTM.indication primitive may issue an MLME-BTM.response primitive with a valid status code not equal to a value of 0 (i.e., Accept) indicating rejection if it is unable to comply with this BSS transition management request.

When a non-AP STA's SME receives an MLME-BTM.indication primitive with the BSS Termination Included field in the Request Mode field equal to 1 it may issue an MLME-BTM.response primitive with the BTM Status Code field set to one of the following values:

- 0 – Accept. Accept the BSS Termination request.
- 4 – Reject, BSS Termination Undesired. Request for deferral of BSS Termination, interval not specified.
- 5 – Reject, BSS Termination Delay. Request for deferral of BSS Termination interval specified in the BSS Termination Delay field in the BSS Transition Management Response frame.

The AP's SME may terminate or delay BSS Termination based on policies that are out of the scope of this standard. The MLME-RESET.request primitive is invoked to terminate the BSS. The AP shall disassociate all STAs immediately prior to termination of the BSS.

When a non-AP STA's SME receives an MLME-BTM.indication primitive with both the Disassociation Imminent and Preferred Candidate List Included fields equal to 0, the non-AP STA's SME shall issue an MLME-BTM.response primitive with the BTM Status Code field set to one of the following values:

- 0 – Accept.
- 2 – Reject, Insufficient Beacon or Probe Response frames received from all candidates.
- 3 – Reject, Insufficient available capacity from all candidates.
- 6 – Reject, STA BSS Transition Candidate List provided.
- 7 – Reject, No suitable BSS transition candidates.
- 8 – Reject, Leaving ESS.

When an AP's SME receives an MLME-BTM.confirm primitive with the BTM Status Code field equal to a value of 2, indicating “Reject, Insufficient Beacon or Probe Response frames received from all candidates,” the AP's SME should generate an MLME-BTM.request primitive with both the Disassociation Imminent and Preferred Candidate List Included fields set to 0 after providing sufficient time for the non-AP STA to perform its scanning procedures.

If the BTM Status Code field is a value of 6, indicating “Reject, STA BSS Transition Candidate List provided,” the non-AP STA shall include a nonempty BSS Transition Candidate List Entries field in the BSS Transition Management Response frame to indicate the non-AP STA's transition preferences. The BTM Status Code field is a value of 8, indicating “Reject, Leaving ESS” if the non-AP STA intends to disassociate from the ESS.

The BSS Transition Candidate List Entries field of a BSS Transition Management Response frame contains zero or more Neighbor Report elements describing the non-AP STA's preferences for target BSS candidates. The Preference field value of a Neighbor Report element used in a BSS Transition Management Response frame shall be between 1 and 255. The value of 0 is reserved. The values between 1 and 255 provide the indication of order, with 255 indicating the most preferred BSS within the given candidate list, decreasing numbers representing decreasing preference relative only to entries with lower values of the Preference field, and equal numbers representing equal preference. The non-AP STA should not list any BSS that is not considered as a target BSS candidate.

When a non-AP STA receives a BSS Transition Management Request frame that has both the Disassociation Imminent and Preferred Candidate List Included fields equal to 1 and a nonempty BSS Transition Candidate List Entries field, if the non-AP STA transmits a BSS Transition Management Response frame to the AP with the BTM Status Code field set to 0 (Accept), then the non-AP STA shall either disassociate from the AP or attempt to (re)associate with an AP corresponding to one of the nonexcluded BSSs in the BSS Transition Candidate List Entries field of the received BSS Transition Management Request frame.

Prior to transitioning to an excluded BSS listed in the BSS Transition Candidate List Entries field of a received BSS Transition Management Request frame, the non-AP STA shall transmit a BSS Transition Management Response frame to the AP indicating the reject reason.

11.24.8 FMS multicast rate processing

An AP that supports FMS indicates its ability to deliver group addressed frames at alternate delivery intervals by its advertisement of the FMS capability. A STA that supports FMS includes the FMS Request element in FMS Request frames to indicate a request to use the FMS service, including use of a higher

multicast rate. The AP selects the TXVECTOR parameters to use with the STA and indicates the rate that these parameters produce and the multicast address in the FMS Response element in the FMS Response frame.

The AP selects TXVECTOR parameters that will be used for transmission to the currently associated STAs requesting FMS service from the AP for the same FMS stream identified by FMSID (the “existing STAs”), and to the requesting STA subject to the following constraints:

- The rate shall not be higher than the lowest rate value provided by the existing STAs and the requesting STA
- The selection of the following TXVECTOR parameters shall be compatible with capabilities declared by the existing STAs and the requesting STA:
 - FORMAT
 - NON_HT_MODULATION
 - PREAMBLE_TYPE
 - MCS
 - CH_BANDWIDTH
 - STBC
 - FEC_CODING
 - GI_TYPE

The STA’s SME may request membership in a multicast group or changes in multicast data rate by issuing an MLME-FMS.request primitive. Upon receipt of an FMS Request frame at the AP’s SME as indicated by reception of the MLME-FMS.indication primitive the AP’s SME shall issue an MLME-FMS.response primitive, indicating the FMS Request element, including the multicast address. The AP may send an FMS Response frame to the STA to change the STA’s multicast rate. When the AP sends an FMS Response frame to the STA with an Element Status field, indicating “Multicast rate changes not allowed,” the STA shall not send further FMS Request frames to request a change in the multicast rate while the STA is associated to the AP.

11.24.9 Collocated interference reporting

Collocated interference may cause degradation of IEEE 802.11 STA performance either periodically or continuously. Collocated interference reporting allows a requesting STA to receive information concerning the collocated interference being experienced by another STA that is operating on the same channel as the requesting STA. Such interference might be due to an interaction between radios where a reporting STA is collocated with another radio device. Collocated interference information might be used by the requesting STA to manage communication to the reporting STA such that the effect of the interference might be limited.

Implementation of Collocated interference reporting is optional for a WNM STA. A STA that implements Collocated Interference reporting has dot11CoLocIntfReportingImplemented equal to true. When dot11CoLocIntfReportingImplemented is true, dot11WirelessManagementImplemented shall be true. A STA whose dot11CoLocIntfReportingActivated is true shall support collocated interference reporting and shall set to 1 the Collocated Interference Reporting field of the Extended Capabilities elements that it transmits.

A requesting STA may request that collocated interference reporting is enabled at another STA that has indicated support for the interference reporting capability. To enable collocated interference reporting, the STA shall send a Collocated Interference Request frame with Automatic Response Enabled bit set to the value representing the requested reporting type; see 9.6.14.13. A STA accepting a request for collocated interference reporting shall send the first report when it has knowledge of collocated interference.

Subsequently, a STA accepting a request with the Automatic Response Enabled subfield equal to 1 shall send a colocated interference report when the temporal characteristics of the interference or the level of the interference caused by colocated interferer significantly change to provide updated information, subject to meeting the Report Timeout requirement. A STA accepting a request with the Automatic Response Enabled subfield equal to 2 or 3 shall send the colocated interference reports periodically using the period included in the Report Period field in the Collocated Interference Reporting element in the report frames. In addition to sending reports periodically, a STA accepting a request with the Automatic Response Enabled field equal to 3 shall send a colocated interference report when the temporal characteristics of the interference or the level of the interference caused by colocated interferer significantly change, subject to meeting the Report Timeout requirement.

The criteria a reporting STA uses for determining significant changes are internal to the reporting STA and outside the scope of this standard. When the reporting STA sends a colocated interference report, it shall restart the Report Period timer for periodic reporting. For either periodic reporting or reporting due to the changes in colocated interference, the reporting STA shall not generate colocated interference reports more frequently than indicated by the Report Timeout field in Interference Request field in the Collocated Interference Request frame.

The requesting STA may disable reporting by sending a Collocated Interference Request frame with the Automatic Response Enabled subfield set to 0. The colocated interference reporting shall be terminated on receipt of a Collocated Interference Request frame with the Automatic Response Enabled subfield equal to 0. All outstanding colocated interference requests are canceled upon a BSS transition and/or channel switch. A new colocated interference request included in the new colocated Interference Request frame supersedes any previously received requests sent by the same STA.

A STA that supports colocated interference reporting may send a Collocated Interference Request frame to another STA that supports colocated interference reporting immediately after they are associated, so that the reporting STA can send a colocated interference report as soon as it has knowledge of colocated interference. The Dialog Token field is the nonzero value received in the corresponding Collocated Interference Request frame which was used to enable reporting.

The reporting STA shall use the Interference Index field in the Collocated Interference Report frame to indicate different types of interference. The reporting STA shall select a unique interference index value for each colocated interference source. For example if the reporting STA has knowledge of colocated interference originating from two interference sources the reporting STA shall report both type of interference using separate Collocated Interference Report elements having separate Interference Index field. Both Collocated Interference Report elements can be sent in the same Collocated Interference Report frame and both can have the same report period. A report with the Interference Index field in the Collocated Interference Report element equal to 0 indicates that no colocated interference is present.

The characteristics of the interference are known a priori without requiring interference detection, measurement, and characterization by the IEEE 802.11 STA. The methods used by a reporting STA to know the periodicity, level of interference, accuracy of the reported interference level, interference center frequency and interference bandwidth are outside the scope of this standard.

11.24.10 QoS Traffic capability procedure

Implementation of the QoS Traffic capability is optional for a WNM STA. A STA that implements QoS Traffic capability has dot11QoSTrafficCapabilityImplemented equal to true. When dot11QoSTrafficCapabilityImplemented is true, dot11WirelessManagementImplemented shall be true. A STA whose dot11QoSTrafficCapabilityActivated is true shall support QoS traffic capability and shall set to 1 the QoS Traffic Capability field of the Extended Capabilities elements that it transmits.

If `dot11QoSTrafficCapabilityActivated` is true, a QoS AP may use the QoS Traffic Capability field values received from a non-AP QoS STA as one of the factors when determining association, reassociation, and the BSS transition of the STA. A non-AP STA in which `dot11QoSTrafficCapabilityActivated` is true may send an Association Request, a Reassociation Request or QoS Traffic Capability Update frame to an AP whose last received Extended Capabilities element contained a value of 1 for the QoS Traffic Capability bit in the Extended Capabilities field.

If `dot11QoSTrafficCapabilityActivated` is true, a non-AP QoS shall construct the QoS Traffic Capability Flags as specified in 9.4.2.78 and 9.6.14.23. QoS Traffic Capability Flags are constructed at the SME of the non-AP QoS STA, from application requirements supplied to the SME. The QoS Traffic Capability Flags are constructed from two application requirements: whether generation of traffic is required for applications and whether a specific UP is required for the generated traffic. If such requirements are supplied to the SME, the SME shall set the flag corresponding to the specific UP to 1.

NOTE—The requirements might be known before the traffic is actually generated. For example, a phone application might be configured to generate UP 6 traffic upon the initiation of a voice session.

Unless application requirements for a specific UP are supplied to the SME, the SME shall set the flag corresponding to the UP to 0.

If `dot11QoSTrafficCapabilityActivated` is true, a non-AP QoS STA shall include the QoS Traffic Capability element in an Association Request frame or in a Reassociation Request frame when it is sending such a frame to associate or reassociate with an AP. If there is any change in QoS Traffic Capability Flags while associated with an AP, the non-AP STA shall send a QoS Traffic Capability Update frame (see 9.6.14.23) including the updated QoS Traffic Capability Flags to the AP.

11.24.11 AC Station Count

Implementation of AC Station Count is optional for a WNM STA. A STA that implements AC Station Count has `dot11ACStationCountImplemented` equal to true. When `dot11ACStationCountImplemented` is true, `dot11WirelessManagementImplemented` and `dot11QoSTrafficCapabilityImplemented` shall be true. When `dot11ACStationCountActivated` is true, the STA shall set the AC Station Count field to 1 in the Extended Capabilities element to indicate that the STA supports the AC station count capability. When `dot11ACStationCountActivated` is false, the STA shall set the AC Station Count field in the Extended Capabilities element to 0 to indicate that the STA does not support this capability.

If `dot11ACStationCountActivated` is true, a QoS AP shall construct the QoS Traffic Capability Bitmask and AC STA Count list as specified in 9.4.2.78. The AP shall construct the STA Count List value based on the UP-to-AC mappings as defined in Table 10-1, the QoS Traffic Capability Bitmask/Flags of the non-AP STAs that are currently associated with it, and additional information. If `dot11ACStationCountActivated` is true, a QoS AP shall include the QoS Traffic Capability element in a Probe Response frame and in a Beacon frame.

If `dot11ACStationCountActivated` is true, a non-AP QoS STA may use the STA Count field values as one of the factors when determining association, reassociation, and the BSS transition. If `dot11ACStationCountActivated` is false, a non-AP QoS STA shall not use the STA Count field values as one of the factors when determining association, reassociation, and the BSS transition.

11.24.12 TFS procedures

11.24.12.1 TFS capability

Implementation of the TFS capability is optional for a WNM STA. A STA that implements TFS shall set `dot11TFSImplemented` to true. If `dot11TFSImplemented` value is true, then

dot11WirelessManagementImplemented shall be true. A STA whose dot11TFSActivated is true shall support TFS and shall set to 1 the TFS field in the Extended Capabilities elements that it transmits.

A STA in which dot11TFSActivated is true may send a TFS Request, TFS Response, TFS Notify frame, or TFS Notify Response frame to a STA within the same infrastructure BSS whose last received Extended Capabilities element contained a value of 1 for the TFS bit in the Extended Capabilities field. The traffic filtering service is not supported in an IBSS.

A traffic filtering agreement is established using a TFS Request frame transmitted from a non-AP STA to an AP STA and a TFS Response frame transmitted from the AP STA to the non-AP STA. At most one traffic filtering agreement can exist at any one time between a STA and its associated AP.

A traffic filtering agreement comprises one or more traffic filter sets, with a logical OR operation on the match conditions of each traffic filter set.

A traffic filter set contains one or more traffic filters, with a logical AND operation on the match conditions of each traffic filter, and also includes a traffic filter set action. The traffic filter set action defines the actions taken at the AP when a frame match occurs. A frame match occurs when a frame matches to the filtering parameters for a TFS traffic filter set.

NOTE—The frame match can occur when the matched frames are either individually addressed or group addressed.

A TFS Request frame contains one or more TFS Request elements. Each traffic filter set is conveyed by one TFS Request element, within a TFS Request frame.

One TFS Request element contains one or more TFS Request subelements. A TFS Request subelement might be a TFS subelement, in which case it contains the filtering parameters for one traffic filter.

A TFS subelement contains one or more TCLAS elements and an optional TCLAS Processing element that defines the relationship among multiple TCLAS elements within the TFS subelement. The TCLAS Processing element shall be present if more than one TCLAS element is included in the TFS subelement.

A TFS Response frame contains the status of the traffic filters requested in the corresponding TFS Request frame.

An AP may propose alternative filtering parameters by returning a TFS subelement in the corresponding TFS Response subelement. (See 11.24.12.2 and 11.24.12.3). When an AP proposes alternative filtering parameters it shall ensure that the TFS subelements related to the traffic filter set specified by a single TFS Request element all fit within a single TFS Response element.

When an AP transmits a TFS Response frame to a STA in which the Status for all traffic filter requests is “Accept”, it shall enable TFS for the STA. The previously established filter parameters, if any, remain in effect when the AP transmits a TFS Response frame with any other Status.

When a traffic filter for group addressed frames is enabled at the AP, the group addressed frames are still delivered, without regard to the frames matching the traffic filter, since other associated STAs may also receive these frames. Because a STA using TFS can be in power save mode for an extended period of time, group addressed frames that match the traffic filter might be delivered before the STA is aware that the traffic filter has been matched. It is likely (but not guaranteed) that the STA does not receive those group addressed frames matching the traffic filter at the scheduled group addressed delivery time. To detect when this might have happened, the STA can request a notification frame be sent when requesting the establishment of the traffic filter. If negotiated with the AP, a frame match is indicated to the non-AP STA via a notification frame.

11.24.12.2 TFS non-AP STA operation

To use the TFS, the non-AP STA's SME that supports TFS shall issue an MLME-TFS.request primitive to send a TFS Request frame. The MLME-TFS.request primitive shall include a valid TFSRequest parameter as defined in the TFS Request elements.

The receipt of an MLME-TSF.confirm primitive with a valid TFSResponse parameter indicates to the STA's SME that the AP has processed the corresponding TFS request. The content of the TFSResponse parameter provides the status of each of the TFS Request elements processed by the AP. A TFSResponse parameter optionally contains modified filtering parameters for the corresponding TFS request.

A TFS Response frame in which the Status for all traffic filter requests is “Accept” indicates to the non-AP STA that the filtering operation at the AP has started. Otherwise, the STA might use the information in the TFS Response frame to form a new TFS request.

In order to request the AP to delete a traffic filter set (identified by a unique TFS ID) when a frame matches to the traffic filter set, a non-AP STA shall set the Delete After Match subfield of the TFS Action Code field of the TFS Request element in the TFS Request frame to 1.

In order to request a TFS Notify frame to be sent by the AP upon a frame match, a non-AP STA shall set the Notify subfield of the TFS Action Code field of the TFS Request element in the TFS Request frame to 1.

After receiving a TFS Notify frame, in order to request the AP to resume generation of the TFS Notify frame upon a future frame match, a non-AP STA shall transmit to the AP a TFS Notify Response frame containing one or more TFS IDs.

The non-AP STA may indicate that it is no longer using a particular TFS Request element by transmitting a TFS Request frame without that TFS Request element. The AP shall send a TFS Response frame with the corresponding Status field value set to Accept, upon receipt of the TFS Request frame.

The non-AP STA may choose to terminate use of the TFS service by sending a TFS Request frame with no TFS Request elements in the request thereby canceling all traffic filters at the AP.

11.24.12.3 TFS AP operation

When an AP's SME receives an MLME-TFS.indication primitive with a valid TFSRequest parameter, it shall issue an MLME-TFS.response primitive with a TFSResponse parameter indicating the status of the associated request.

An AP establishes a traffic filtering agreement and starts the filtering operation defined by that traffic filtering agreement when it receives a MLME-TFS.response primitive in which the Status for all traffic filter requests is “Accept”.

When the AP establishes a traffic filtering agreement for a requesting STA, the AP shall add to the traffic filtering agreement a traffic filter set that matches individually addressed EAPOL-Key frames addressed to the requesting STA, with bits 0 and 1 of the TFS Action Code field set to 0, without any status indication for this traffic filter set in the TFS Response frame.

When an AP's SME receives an MLME-TFS.indication primitive with a valid TFSRequest parameter having a requested TCLAS-based classifier which it is unable to provide, the SME shall issue an MLME-TFS.response primitive indicating the status of the corresponding request and may include a TFSResponse parameter having a suggested alternative TCLAS-based classifier.

When a traffic filtering agreement is established for a STA, the AP shall discard all individually addressed frames destined for the STA until a frame is found that matches one or more traffic filter sets within the traffic filtering agreement. When a frame is found that matches one or more of the traffic filter sets within the traffic filtering agreement (a matching frame), the AP shall perform the following actions:

- If the traffic filter set action specifies both Delete After Match and Notify, then the AP shall generate a single individually addressed TFS Notify frame for the frames matching to the traffic filter set identified by the corresponding TFS ID. Subsequently, the AP shall delete the traffic filtering agreement.
- If the traffic filter set action specifies Notify but not Delete After Match, then the AP shall generate a single individually address TFS Notify frame for all frames matching to the traffic filter set identified by the corresponding TFS ID. All traffic filter sets established at the AP for the non-AP STA remain to be effective upon a match. If the AP receives a TFS Notify Response frame from the corresponding non-AP STA, the AP resumes generation of a single individually addressed TFS Notify frame for the next frame matching to the traffic filter sets identified by the TFS IDs included in the TFS Notify Response frame. Otherwise, the AP shall not send additional TFS Notify frames upon frame matches.

NOTE—Due to the operation of group addressed frame delivery, a group addressed frame that matches a traffic filter might result in the STA receiving indication of the group addressed frame either before or after the group addressed frame is transmitted by the AP, if the TFS Notify frame is queued in the STA's power save queue. This might result in the STA receiving the group addressed frame in some cases and not receiving it in other cases.

Upon receiving an MLME-TFS.indication primitive, the AP's SME shall disregard any previous MLME-TFS.indication primitive received from the same STA.

The AP shall terminate any TFS operation for a STA when no traffic filters remain for a STA or if the AP's SME receives an MLME-TFS.indication primitive with a null TFSRequest.

11.24.13 BSS max idle period management

If dot11BssMaxIdlePeriod is a nonzero, the STA shall include the BSS Max Idle Period element in the Association Response frame or the Reassociation Response frame. Otherwise, the STA shall not include the BSS Max Idle Period element in the Association Response frame or the Reassociation Response frame. A STA may send protected or unprotected keepalive frames, as indicated in the Idle Options field.

The Max Idle Period field of the BSS Max Idle Period element indicates the time period during which a STA can refrain from transmitting frames to its associated AP without being disassociated. A non-AP STA is considered inactive if the AP has not received a Data frame, PS-Poll frame, or Management frame (protected or unprotected as specified in this paragraph) of a frame exchange sequence initiated by the STA for a time period greater than or equal to the time specified by the Max Idle Period field. If the Idle Options field requires protected keepalive frames, then the AP may disassociate the STA if no protected frames are received from the STA for a period indicated by the Max Idle Period field of the BSS Max Idle Period element. If the Idle Options field allows unprotected or protected keepalive frames, then the AP may disassociate the STA if no protected or unprotected frames are received from the STA for a duration indicated by the Max Idle Period field of the BSS Max Idle Period element.

NOTE—The AP can disassociate or deauthenticate the STA at any time for other reasons even if the STA satisfies the keep-alive frame transmission requirements.

11.24.14 Proxy ARP (including Proxy Neighbor Discovery) service

Implementation of the proxy ARP service is optional for a WNM STA. A STA that implements the proxy ARP service has dot11ProxyARPImplemented equal to true. When dot11ProxyARPImplemented is true, dot11WirelessManagementImplemented shall be true. When dot11ProxyARPActivated is true, the Proxy ARP Service bit in the Extended Capabilities field shall be set to 1 to indicate that the AP supports the proxy

ARP service. When `dot11ProxyARPAactivated` is false, the Proxy ARP Service bit shall be set to 0 to indicate that the AP does not support the proxy ARP service.

When the AP sets the Proxy ARP field to 1 in the Extended Capabilities element, the AP shall maintain a Hardware Address to Internet Address mapping for each associated station, and shall update the mapping when the Internet Address of the associated station changes. When the IPv4 address being resolved in the ARP request packet (IETF RFC 826) is used by a non-AP STA currently associated to the BSS, the proxy ARP service shall respond on behalf of the STA to an ARP request (IETF RFC 925) or an ARP Probe (IETF RFC 5227).

When an AP receives an ARP Request from one associated STA or from the DS with a Target IP Address that corresponds to a second associated STA, the AP shall insert the second STA MAC address as the Sender's MAC Address in the ARP Response packet.

When an IPv6 address is being resolved, the Proxy Neighbor Discovery service shall respond with a Neighbor Advertisement message (Section 4.4, IETF RFC 4861) on behalf of an associated STA to an Internet Control Message Protocol version 6 (ICMPv6) Neighbor Solicitation message (Section 4.3, IETF RFC 4861). When MAC address mappings change, the AP may send unsolicited Neighbor Advertisement Messages on behalf of a STA.

NOTE—The Neighbor Solicitation message is used for both address discovery and duplicate address detection (IETF RFC 4862).

11.24.15 Channel usage procedures

Channel Usage information is a set of channels provided by an AP to non-AP STAs for operation of a noninfrastructure network or an off-channel TDLS direct link. The Channel Usage information provided by the AP to the non-AP STA is to advise the STA on how to co-exist with the infrastructure network.

Implementation of Channel Usage is optional for a WNM STA. A STA that implements Channel Usage has `dot11ChannelUsageImplemented` equal to true. When `dot11ChannelUsageImplemented` is true, `dot11WirelessManagementImplemented` shall be true, or the STA shall be capable of acting as an S-AP within a CCSS. A STA whose `dot11ChannelUsageActivated` is true shall support channel usage and shall set to 1 the Channel Usage field of the Extended Capabilities elements that it transmits.

A non-AP STA that supports Channel Usage and is not associated to an AP prior to using a noninfrastructure network or an off channel TDLS direct link may transmit a Probe Request frame including both Supported Operating Classes and Channel Usage elements. A non-AP STA supporting Channel Usage may send a Channel Usage Request frame at any time after association to the AP that supports the use of Channel Usage to request the Channel Usage information for supported operating classes.

Upon receipt of a Channel Usage element in the Probe Request frame, the AP supporting Channel Usage shall send a Probe Response frame including one or more Channel Usage elements. Upon receiving a Channel Usage Request frame, the AP supporting Channel Usage shall send a Channel Usage Response frame including one or more Channel Usage elements. Channel Usage elements shall include channels that are valid for the regulatory domain in which the AP transmitting the element is operating and consistent with the Country element in the Beacon or Probe Response frame; the Channel Usage elements shall not include any other channels. When the Channel Usage element in a received Probe Request or Channel Usage Request frame includes one or more Operating Class/Channel Pair fields, the Operating Class/Channel Pair field(s) indicate(s) the requested non-AP STA operating class/channels for the usage mode indicated in the frame.

The AP may send an unsolicited group addressed or individually addressed Channel Usage Response frame to the STAs that have requested Channel Usage information if the corresponding Channel Usage information needs to be updated. The Country element shall be included in the unsolicited and/or group

addressed Channel Usage Response frame. The AP may include the Power Constraint information and EDCA Parameter in the Channel Usage Response frame. The values of the fields in the Power Constraint and EDCA Parameter Set elements included in the Channel Usage Response frame shall be the same values of the fields in the Power Constraint and EDCA Parameter Set elements that are transmitted by the AP.

Upon receipt of a Channel Usage element in the Probe Response or Channel Usage Response frame, the receiving STA may use the following:

- The channel usage information as part of channel selection processing to start a noninfrastructure network or an off-channel TDLS direct link
- The Power Constraint element, if present, as part of determining its maximum transmit power for transmissions for the noninfrastructure network or an off-channel TDLS direct link
- The EDCA Parameter Set element, if present, as part of determining its EDCA parameters for transmissions for the noninfrastructure network or an off-channel TDLS direct link
- The QMF Policy element, if present and dot11QMFActivated is true, as part of determining its classification of Management frames for transmissions for the noninfrastructure network or an off-channel TDLS direct link

If either a recommended operating class, or a recommended channel, or both are not supported or understood by the recipient, or if the operating country of the sender is unknown, the recipient shall discard the corresponding channel usage recommendation. A STA that has not requested Channel Usage information shall discard an unsolicited group addressed Channel Usage Response frame.

11.24.16 Group addressed transmission service

11.24.16.1 General

The group addressed transmission service provides delivery of group addressed frames and comprises the two services, DMS and GCR. DMG STAs do not use GCR.

11.24.16.2 DMS procedures

In this subclause, the following terms are used:

- *DMS provider*: An AP, PCP, or DMG STA associated with a PCP that provides DMS.
- *DMS recipient*: A non-AP STA that uses DMS.

Directed multicast service (DMS) is a service that may be provided by a DMS provider to its associated DMS recipients that support DMS, where the DMS provider transmits group addressed MSDUs as individually addressed A-MSDUs.

In a PBSS, DMS is a service that may be provided by any STA to other STAs associated in the same PBSS that support DMS, where the STA transmits group addressed MSDUs as individually addressed A-MSDUs. If the PCP of the PBSS has the PCP Forwarding field within the PCP's DMG Capabilities element set to 0, a non-PCP STA in the PBSS shall not use the PCP as a DMS provider in the PBSS.

Implementation of DMS is optional for a WNM STA and mandatory for a robust AV streaming STA (as defined in 11.27.1). A STA that implements DMS has dot11DMSImplemented equal to true. When dot11DMSImplemented is true, at least one of dot11WirelessManagementImplemented and dot11RobustAVStreamingImplemented shall be true. When dot11DMSImplemented is true, either dot11HighThroughputOptionImplemented or dot11DMGOptionImplemented shall be true. A STA whose dot11DMSActivated is true shall support DMS and shall set to 1 the DMS field of the Extended Capabilities elements that it transmits.

A DMS recipient that supports DMS may request use of DMS of one or more flows by sending a DMS Request frame or Reassociation Request frame that includes a DMS Request element containing one or more DMS Descriptors with the Request Type field set to “Add” per flow. Each DMS Descriptor field in the DMS Request element identifies group addressed frames that shall be transmitted to the requesting DMS recipient as individually addressed frames in addition to the group address frame transmission. In the TCLAS element, the Classifier Type subfield shall be set to the value 0, 1, or 4, and the Destination Address or Destination IP Address subfield shall be set to the multicast address of the flow that the STA requests to receive as individually addressed frames. In the TSPEC element, the STA may define the characteristics and QoS expectations of the corresponding traffic flow.

Upon receipt of a DMS Request frame or Reassociation Request frame from a DMS recipient, the DMS provider shall respond with a corresponding DMS Response frame or Reassociation Response frame. The response frame shall contain a matching (i.e., as the same DMSID) DMS Status field for each received DMS Descriptor field preserving the order present in the request frame.

NOTE—There is no requirement that the number of DMS Request elements and the number of DMS Response elements match. There is no requirement that the number of DMS Descriptor fields within any DMS Request element matches the number of DMS Status fields within any DMS Response element.

If the DMS provider accepts a DMS request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to “Accept” and a nonzero DMSID is assigned. A Response Type value of “Deny” shall be set in the corresponding Response Type field of the DMS Status field in the DMS Response element when the DMS provider denies a DMS request identified by a DMS Descriptor, and the DMSID shall be set to 0. If the Response Type field is set to “Accept” or “Denied,” then the TCLAS Elements, TCLAS Processing Element, TSPEC Element and Optional Subelements fields of a DMS Status field in a DMS Response element shall be copied from the respective TCLAS Elements, TCLAS Processing Element, TSPEC Element and Optional Subelements fields of the corresponding DMS request. When one or more STAs send a DMS request to an DMS provider, containing a DMS descriptor with a set of TCLAS element and TCLAS Processing elements that are identical irrespective of ordering to another successfully received DMS request that is not yet terminated, the DMS provider shall assign the same DMSID as was assigned to the previous DMS request.

When the DMS provider denies the DMS Request, it may suggest an alternative TCLAS-based classifier by including one or more TCLAS elements and an optional TCLAS Processing element. The DMS provider may include fewer TCLAS elements in the DMS Response element than were present in the request; when the DMS provider’s response includes a single TCLAS element, it shall not include a TCLAS Processing element. If the DMS provider changes a TCLAS element’s Classifier Type field in the DMS Response element but is unable to suggest a value for the Classifier Mask field, it shall set that field to 0. If the DMS provider changes a TCLAS element’s Classifier Type field or Classifier Mask field in the DMS Response element but is unable to suggest values for one or more Classifier Parameter subfields, it shall set those subfields to 0.

A DMS recipient receiving a DMS Response frame containing a modified TCLAS element having a Classifier Mask field equal to 0 or having one or more Classifier Parameter subfields equal to 0 shall interpret the values of 0 to mean that no suggested value has been provided by the DMS provider.

If the requested DMS is accepted by the DMS provider, the DMS provider shall send subsequent group addressed MSDUs that match the frame classifier specified in the DMS Descriptors to the requesting STA as A-MSDU subframes within an individually addressed A-MSDU frame (see 9.3.2.2 and 10.12). The A-MSDU shall be formatted as specified in 9.3.2.2 which includes the A-MSDU subframe headers’ DA address set to the multicast address for the corresponding MSDUs. The DMS provider shall continue to transmit the matching frames as group addressed frames (see 10.3.6, and 11.2.3.16) if at least one associated STA has not requested DMS for these frames.

A DMS recipient may request modification of the traffic characteristics or attributes of one or more accepted DMS traffic flows by sending a DMS Request frame or Reassociation Request frame containing one or more DMS Descriptors with the Request Type set to “Change” and with the DMSIDs that identify the DMS traffic flows to be modified. If the Request Type of a DMS Descriptor is set to “Change,” then the values of at least one of the TSPEC Element and Optional Subelement fields shall be different from those of the accepted DMS traffic flow corresponding to the DMSID.

If the DMS provider accepts a DMS change request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to “Accept” and the DMSID shall be set to that of the DMS Descriptor. If the DMS provider denies a DMS change request identified by a DMS Descriptor, the Response Type field of the corresponding DMS Status field in the DMS Response element shall be set to “Deny” and the DMSID shall be set to that of the DMS Descriptor. When the DMS provider denies a DMS change request identified by a DMS Descriptor, the existing DMS traffic flow of the corresponding DMSID shall remain unchanged.

The DMS recipient may request removal of one or more accepted DMS traffic flows by sending a DMS Request frame or Reassociation Request frame that includes a DMS Request element containing one or more DMS Descriptors with the Request Type set to “Remove” and the DMSID field set to that of the accepted DMS traffic flow to be removed. The DMS Length field in this DMS Descriptor is set to 1. The TLCAS Elements, TLCAS Processing Element TSPEC Element and Optional Subelements fields shall not be included in the DMS Descriptor if the Request Type is set to “Remove.” The DMS provider shall terminate individually addressed frame delivery for the requested group addressed frames identified by the DMSID for the requesting DMS recipient upon receipt of a DMS Request frame or Reassociation Request frame with the Request Type field equal to “Remove.” The DMS provider shall respond to the termination request by sending a DMS Response frame including the corresponding DMSID and a Response Type value of “Terminate” in the Response Type field of the corresponding DMS Status field. The DMS Length field in this DMS Status field is set to 3. The TLCAS Elements, TLCAS Processing Element, TSPEC Element and Optional Subelement fields shall not be included in the DMS Status field if the Response Type field is set to “Terminate.”

The DMS provider may send an unsolicited DMS Response frame at any time to cancel a granted DMS identified by the DMSID by including the DMSID and a Response Type value of “Terminate” in the DMS Status field. The DMS provider may reject a new DMS or cancel a granted DMS at any time based on network condition, for example the number of associated STAs and channel load.

The DMS recipient shall keep a list of group addresses for which the DMS recipient has requested DMS and that have been accepted by the DMS provider. The requesting STA shall discard group addressed frames that match a group address in this list until the DMS has been terminated. When the DMS is terminated, and if the sequence number value is provided in the Last Sequence Control field in the DMS Response frame, using the value of the Last Sequence Control field, the DMS recipient shall discard the group addressed frames that are the duplicates of the individually addressed frames.

NOTE—When the Last Sequence Control field in the DMS Response frame is not supported at the DMS provider (i.e., the sequence number value is not provided in the field), and a multicast MSDU that has sent using both individually addressed and group addressed frame transmission, termination of the DMS stream by the DMS provider might result in a DMS recipient receiving undetectable duplicate MSDUs that are not filtered out by the MAC.

If the length of the DMS Descriptors exceeds 255 octets, then multiple DMS Request elements shall be included, each containing only those DMS Descriptors that are completely contained within 255 octets. If the length of the DMS status fields exceeds 255 octets, then multiple DMS Response elements shall be included, each containing only those DMS Status fields that are completely contained within the first 255 octets.

If the DMS recipient supports both DMS and FMS, the DMS recipient shall not request both services for the same group addressed frames simultaneously. The DMS recipient may request the different service (DMS vs. FMS) for different group addressed frames.

If the DMS provider supports both DMS and TFS, the DMS provider shall first apply TFS to the frame and then apply DMS.

11.24.16.3 GCR procedures

11.24.16.3.1 Overview

Groupcast with retries (GCR) is a flexible service to improve the delivery of group addressed frames while optimizing for a range of criteria. GCR service may be provided by the AP to associated STAs in an infrastructure BSS or by a mesh STA to its peer mesh STAs in a mesh BSS. GCR uses the setup, modification, and termination procedures defined 11.24.16.2. The differences between GCR procedures and DMS procedures are as follows:

- a) A GCR agreement applies to a single group address and, if a TCLAS Processing element is present, it has the Processing subfield value set to 0, whereas a DMS flow is not restricted to a single group address.
- b) DMS offers multicast-to-unicast conversion only, whereas GCR includes several retransmission policies and delivery methods.

A non-DMG STA with dot11RobustAVStreamingImplemented true shall implement the GCR procedures defined in 11.24.16.3.2 to 11.24.16.3.6. When dot11RobustAVStreamingImplemented is true, dot11DMSImplemented and dot11HighThroughputOptionImplemented shall be true. A STA that implements advanced GCR supports GCR block ack (11.24.16.3.7) and GCR-SP (11.24.16.3.8) and has dot11AdvancedGCRImplemented equal to true. When dot11AdvancedGCRImplemented is true, dot11RobustAVStreamingImplemented shall be true. In a mesh BSS, a STA that implements GCR has dot11MeshGCRImplemented equal to true. When dot11MeshGCRImplemented is true, dot11HighThroughputOptionImplemented shall be true.

DMS allows the transmission of group addressed MSDUs as individually addressed A-MSDUs and is particularly suited to small numbers of group members. It provides a high level of reliability but has low scalability as the efficiency decreases and delay increases proportionally to the number of group members.

GCR employs the DMS Request and DMS Response elements with the addition of GCR Request and Response subelements, respectively, for administering the announcement, setup, modification, and teardown of GCR services between an AP and non-AP STAs or between peer mesh STAs. The DMS procedures and state machine of 11.24.16.2 shall apply to GCR with the extensions and constraints specific to GCR described below in 11.24.16.3.3 to 11.24.16.3.8.

Along with the No-Ack/No-Retry or non-GCR (defined in 10.3.6) and the DMS (defined in 11.24.16.2) retransmission mechanisms, GCR defines two additional retransmission policies for group addressed frames:

- GCR unsolicited retry
- GCR block ack

When using the GCR unsolicited retry retransmission policy for a group address, the STA providing GCR service retransmits an MSDU one or more times (subject to applicable retry or lifetime limits) to increase the probability of correct reception at STAs that are listening to this group address. The decision to retransmit these MSDUs is implementation dependent. GCR unsolicited retry is particularly suited to use with large numbers of group members as it has moderate delay, efficiency, and reliability, but high scalability.

The GCR block ack retransmission policy extends the block acknowledgment mechanism to group addressed frames. The STA providing the GCR service initiates block ack agreements with each STA receiving GCR frames that supports GCR block ack for a particular group address. Once this block ack agreement is in place, the STA providing GCR service regularly sends BlockAckReq frames to the STAs receiving the frames to ascertain the reception status of MSDUs related to this group address, as described in 10.24.10. This allows the STA providing GCR service to discover MSDUs that have not been received and to schedule their retransmission. GCR block ack is particularly suited to use with moderate numbers of group members as it has moderate delay, high efficiency, and moderate scalability and reliability.

The GCR service has two delivery methods for group addressed frames:

- Non-GCR-SP
- GCR-SP (see 11.24.16.3.8)

The non-GCR-SP delivery method may be provided using one or more of the following:

- FMS (see 11.2.3.16)
- Transmit frames in a GCR stream after the DTIM Beacon frame if any STA in the GCR group is in PS mode
- Transmit frames at any time if all STAs in the GCR group are in active mode in an infrastructure BSS
- In accordance with 14.14 in a mesh BSS

GCR-SP transmits GCR group addressed frames at intervals, where the interval between transmissions might be smaller than the beacon interval. Compared to non-GCR-SP, GCR-SP might provide lower delay and jitter.

11.24.16.3.2 GCR group membership procedures

The procedures described in 11.24.16.3.3 to 11.24.16.3.8 depend upon the AP or mesh STA knowing the membership of the multicast groups of STAs that support GCR.

One method for an AP to discover the multicast groups that its associated STAs are receiving or for a mesh STA to discover the multicast groups that its peer mesh STAs are receiving is to use the Group Membership Request frame (as defined in 9.6.19.4) to request the contents of the dot11GroupAddressesTable of its associated STAs or peer mesh STAs.

Other methods of group membership detection are also possible, using information that is outside the scope of this standard. For example, group membership detection could be achieved by inspecting the protocol messages of IETF RFC 3376.⁴⁶

An AP may transmit a Group Membership Request frame as an individually addressed frame to an associated STA that has indicated that it supports robust AV streaming (as indicated by the Robust AV Streaming bit equal to 1 in the Extended Capabilities element) to request the associated STA's dot11GroupAddressesTable. An AP shall not send a Group Membership Request frame to an associated STA that has the Robust AV Streaming bit equal to 0 in its Extended Capabilities element.

A STA for which dot11GCRActivated or dot11MeshGCRActivated is true shall reply to a Group Membership Request frame by sending a Group Membership Response frame with the Dialog Token field set to the value from the Group Membership Request frame, the Address Count field set to the number of entries in the dot11GroupAddressesTable, and the Group Address List field set to the group MAC addresses in the dot11GroupAddressesTable. A STA for which dot11GCRActivated or dot11MeshGCRActivated is

⁴⁶ IETF RFC 3376, Internet Group Management Protocol (IGMP).

true shall set dot11GCRGroupMembershipAnnouncementActivated to true upon reception of a Group Membership Request frame.

A STA for which dot11GCRGroupMembershipAnnouncementActivated and at least one of dot11MeshGCRAutowired and dot11GCRAutowired are true shall send an unsolicited Group Membership Response frame with the Dialog Token field set to 0, the Address Count field set to the number of entries in the dot11GroupAddressesTable, and the Group Address List field set to the group MAC addresses in the dot11GroupAddressesTable, every time the contents of the dot11GroupAddressesTable is modified.

If an unsolicited Group Membership Response frame is sent by an associated STA, the frame shall be transmitted as an individually addressed frame to the AP with which it is associated. If an unsolicited Group Membership Response frame is sent by a mesh station in a mesh BSS, the frame shall be transmitted as a broadcast frame.

11.24.16.3.3 GCR setup procedures

An AP with dot11GCRAutowired true may transmit to an associated non-AP STA an unsolicited individually addressed DMS Response frame that contains one DMS Status field with a GCR Response subelement per group address, if it detects that the associated non-AP STA meets all of the following conditions:

- Robust AV Streaming was equal to 1 in the Extended Capabilities element in the most recently received (Re)Association Request frame from the non-AP STA.
- The non-AP STA is receiving one or more group addresses for which there is an active GCR service.
- The non-AP STA does not have a GCR agreement for one or more of these group addresses.

A mesh STA with dot11MeshGCRAutowired true may transmit to a peer mesh STA an unsolicited individually addressed DMS Response frame that contains one DMS Status field with a GCR Response subelement per group address, if it detects that the peer mesh STA meets all of the following conditions:

- Mesh GCR was equal to 1 in the Extended Capabilities element in the most recently received mesh beacon from the peer mesh STA.
- The peer mesh STA is receiving one or more group addresses for which there is an active GCR service.
- The peer mesh STA does not have a GCR agreement for one or more of these group addresses.

Each DMS Status field includes a TCLAS element to identify the GCR group address, the DMSID corresponding to this GCR traffic flow, and other associated parameters. The Status subfield of this DMS Status field shall be set to “GCR Advertise.” A STA that receives this DMS Response frame from its AP may initiate a GCR agreement for one or more of the group addresses contained in the frame.

A STA requests use of the GCR service for a group address by sending a DMS Descriptor (as described in 11.24.16.2) with the following modifications:

- The DMS Descriptor shall contain one TCLAS element with the frame classifier type equal to 0 (Ethernet parameters), one TSPEC element, and one GCR Request subelement.
- In addition, the DMS Descriptor may contain other TCLAS elements.
- When there are multiple TCLAS elements, a TCLAS Processing element shall be present, and the Processing subfield in the TCLAS Processing element shall be set to 0. Otherwise, no TCLAS Processing elements shall be present in the DMS Descriptor.
- The TSID subfield within the TS Info field of the TSPEC element shall be reserved. Since the AP might choose a delivery method of GCR-SP, the non-AP STA should set the Minimum Service Interval, Maximum Service Interval, and Service Start Time fields in the TSPEC element to indicate the STA’s preferred wakeup schedule. In a mesh BSS, the Delivery Method field shall not be set to “GCR-SP.”

- The GCR Request subelement specifies the retransmission policy and delivery method requested by the non-AP STA for the group addressed stream.

A STA shall not request transmission of a group address via the GCR service while it has an active DMS for this group address. A STA shall not request transmission of a group address via DMS while it has an active GCR service for this group address.

An AP or mesh STA accepts a GCR request by sending a DMS Response frame with a DMS Response element that contains a DMS Status field with the Response Type field set to “Accept” (as described in 11.24.16.2) with the following modifications:

- The DMS Status field shall include a GCR Response subelement indicating the retransmission policy, delivery method, and GCR concealment address for the group addressed stream. The Retransmission Policy field shall not be set to “No Preference.” The Delivery Method field shall not be set to “No Preference.” The GCR Concealment Address field of the GCR Response subelement shall be set to dot11GCRConcealmentAddress. In a mesh BSS, the Delivery Method field shall not be set to “GCR-SP.”
- If the GCR group addressed stream is subject to the GCR-SP delivery method, then the AP shall also include a Schedule element in the DMS Status field indicating the wakeup schedule for the group addressed stream.
- If a TSPEC Element is included, the TSID subfield shall be set to 0.

For each GCR Request subelement, the AP or mesh STA may

- Adopt the requested retransmission policy and delivery method, or
- Maintain its existing retransmission policy and delivery method, or
- Select an alternate retransmission policy and delivery method, or
- Deny GCR service for the group addressed stream.

In an infrastructure BSS, the retransmission policy shall not be GCR block ack for a GCR group address while the AP has a GCR agreement for the group address with a non-AP STA that had the Advanced GCR field equal to 0 in the Extended Capabilities element in the (Re)Association Request frame most recently received by the AP.

In a mesh BSS, the retransmission policy shall not be GCR block ack for a GCR group address while the mesh STA has a GCR agreement for the group address with a peer mesh STA that had the Mesh GCR field equal to 0 in the Extended Capabilities element.

An AP or mesh STA denies a GCR request by sending a DMS Response frame with a DMS Response element that contains a DMS Status field with

- The Response Type field set to “Deny” (as described in 11.24.16.2) and
- An empty GCR Response subelement.

If an AP or mesh STA denies a GCR request, it may suggest an alternative TCLAS-based classifier by including one or more TCLAS elements and an optional TCLAS Processing element (as described in 9.4.2.33). One TCLAS element shall be included in the DMS Descriptor with the frame classifier type equal to 0 (Ethernet parameters). Other TCLAS elements may be included in the DMS Descriptor, but, if present, a TCLAS Processing element with the Processing subfield equal to 0 shall also be included.

If a STA requesting GCR service determines that one or more GCR Response subelements are unacceptable, then the STA shall discard any received ADDBA Request frames for the unacceptable GCR streams and shall send a new DMS Request frame containing a DMS Request element with one DMS Descriptor for each

unacceptable GCR stream. The DMSID fields shall be set to the DMSIDs of the unacceptable streams, and the Request Type field shall be set to “Remove.”

In an infrastructure BSS, if the non-AP STA accepts the response to its GCR request, the non-AP STA shall set dot11GCRConcealmentAddress to the value contained in the GCR Concealment Address field of the GCR Response subelement.

In a mesh BSS, if a STA requesting GCR service accepts the response to its GCR request, it shall add to dot11GroupAddressesTable the value contained in the GCR Concealment Address field of the GCR Response subelement.

In a mesh BSS, a GCR agreement instance is identified by a GCR agreement instance identifier. The mesh GCR agreement instance consists of the DMSID, localMAC, peerMAC, and concealment address.

For each group addressed stream requested by the non-AP STA and accepted by the AP, the AP shall immediately initiate a block ack negotiation if both of the following conditions are true:

- The AP advertised an Advanced GCR field equal to 1 in its Extended Capabilities element.
- The non-AP STA advertised an Advanced GCR field equal to 1 in the Extended Capabilities element in the (Re)Association Request frame most recently received by the AP.

For each group addressed stream requested by a mesh STA’s peer (STA1), the mesh STA (STA2) receiving the request shall immediately initiate a block ack negotiation if STA2 transmitted a Mesh GCR field equal to 1 in the Extended Capabilities element in its mesh Beacon frame and STA2 received a mesh Beacon frame from STA1 in which the Mesh GCR field in the Extended Capabilities element is equal to 1.

If all of the above conditions are true, the AP or mesh STA shall immediately initiate a block ack negotiation by sending an ADDBA Request frame to the STA that originated the GCR request. The Block Ack Policy subfield in the Block Ack Parameter Set field within the ADDBA Request frame shall not be set to 0. The TID subfield in the Block Ack Parameter Set field within the ADDBA Request frame shall be set to 0. The A-MSDU Supported subfield within the ADDBA Request frame shall be set to 1 (A-MSDU permitted). The Starting Sequence Number field within the ADDBA Request frame shall be greater than (modulo 4096) the last sequence number of the last group address frame transmitted before the ADDBA Request frame. A STA shall maintain this block ack agreement for the duration of its GCR agreement, irrespective of whether GCR block ack is the current retransmission policy. While the retransmission policy of the GCR group addressed stream is DMS, the STA receiving GCR frames shall suspend its block ack processing for the group addressed stream.

NOTE—Having a block ack agreement with all members of a GCR group address allows the AP or mesh STA to change the GCR retransmission policy dynamically.

For each GCR agreement, there shall be only one retransmission policy and delivery method active at any time. A GCR agreement between a non-AP STA and an AP or between peer mesh STAs shall begin when the STA providing GCR service successfully transmits an individually addressed DMS Response frame with a DMS Response element containing a DMS Status field that has the Status field set to “Accept” (as described in 11.24.16.2) with the DMS Status field including a GCR Response subelement.

11.24.16.3.4 GCR frame exchange procedures

In an infrastructure BSS, a GCR block ack agreement exists between a non-AP STA and an AP for a group addressed stream from when the non-AP STA successfully transmits an ADDBA Response frame until one of the following situations occurs:

- The AP or non-AP STA successfully transmits a DELBA frame to the other party.
- The GCR agreement no longer exists.

In a mesh BSS, a GCR block ack agreement exists between a mesh STA and its peer mesh STA for a group addressed stream from the time when the mesh STA successfully transmits an ADDBA Response frame to the peer mesh STA until one of the following situations occurs:

- The mesh STA or the peer mesh STA successfully transmits a DELBA frame to the other party.
- This GCR block ack agreement expires (see 10.24.5).
- The GCR agreement is terminated.

An AP or a mesh STA may transmit a group addressed stream via the No-Ack/No-Retry (non-GCR; see 10.3.6) service and GCR service simultaneously. Each frame shall be transmitted via the No-Ack/No-Retry retransmission policy before it is transmitted via the GCR service, except when using the GCR-SP delivery method. The AP may transmit each frame via the No-Ack/No-Retry retransmission policy before or after it transmits the frame via the GCR service when using the GCR-SP delivery method. A STA providing GCR service may switch between the DMS, GCR block ack, or GCR unsolicited retry retransmission policies, but only one delivery mode may be active at any given time for each GCR group address.

An AP or mesh STA shall transmit a frame belonging to a group address via the GCR service if any associated STA or peer mesh STA has a GCR agreement for the group address and, otherwise, does not transmit the frame via the GCR service.

In an infrastructure BSS, an AP shall transmit a frame belonging to a group address via the No-Ack/No-Retry service if one or more of the following situations occur:

- The group address is the broadcast address.
- The group address is not the broadcast address, and at least one associated STA has the Robust AV Streaming bit equal to 0 in the Extended Capabilities element of the STA's most recent (Re)Association Request frame and has been determined by the AP to be a member of the group address (how this determination is made is out of the scope of this standard).
- The group address is not the broadcast address, at least one non-AP STA has a block ack agreement for the group address, and the frame precedes the start of the block ack agreement (the sequence number of the frame is less than the starting sequence number of the block ack agreement, as described in 10.24.2).

In a mesh BSS, a mesh STA providing GCR service shall transmit a frame belonging to a group address via the No-Ack/No-Retry service if one or more of the following situations occur:

- The group address is the broadcast address.
- The group address is not the broadcast address, and at least one peer mesh STA has the Mesh GCR bit equal to 0 in the Extended Capabilities element of the STA's most recent mesh Beacon frame and has been determined to be a member of the group address (how this determination is made is out of the scope of this standard).
- The group address is not the broadcast address, at least one peer mesh STA has a block ack agreement for the group address, and the frame precedes the start of the block ack agreement (the sequence number of the frame is less than the starting sequence number of the block ack agreement, as described in 10.24.2).

When the AP updates the retransmission policy, the AP shall set the Last Sequence Control field in the GCR Response subelement to the sequence number of the MPDU corresponding to the GCR traffic flow that is being updated that was delivered prior to the change in retransmission policy.

To avoid undetected retries being passed up at a receiver's MAC SAP, duplicate detection and removal for group addressed frames is required in STAs with dot11RobustAVStreamingImplemented true or dot11MeshGCRImplemented true (see 10.3.2.11).

GCR frames shall be QoS Data frames (with QoS subfield of the Subtype subfield set to 1).

If the block ack agreement is successfully established for the group addressed stream and the delivery method for the group addressed stream is GCR-SP, then the non-AP STA is awake for subsequent SPs (see 11.24.16.3.8).

A STA may request a change of GCR service for a group addressed stream by sending a DMS Descriptor with the DMSID identifying the group address and the Request Type field set to “Change” (as described in 11.24.16.2) with the following modifications:

- The DMS Descriptor shall contain zero TCLAS elements, zero TCLAS Processing elements, one TSPEC element, and one GCR Request subelement.
- The TSPEC element and GCR Request subelement of this DMS Descriptor shall together contain at least one field that is different from the original TSPEC element and GCR Request subelement identified by the DMSID.

An AP or mesh STA may update the retransmission policy, delivery method, and schedule for any reason, such as the size of the group changes, the capabilities of the members of the group change, GCR Request subelements for the group are received, or multicast diagnostics are needed. The AP or mesh STA advertises the current settings upon a change and periodically by either of the following methods:

- Transmitting an unsolicited DMS Response frame with the current settings addressed to the GCR concealment address. This DMS Response frame shall be scheduled for delivery at the appropriate DTIM interval or SP in which all STAs within the group are awake to receive the frame. One TCLAS element shall be included with the frame classifier type equal to 0 (Ethernet parameters). Other TCLAS elements may be present, but if present, a TCLAS Processing element with the Processing subfield equal to 0 shall also be included. One TSPEC element and one GCR subelement shall be included per DMS Descriptor in the DMS Response element of the DMS Response frame to identify each GCR stream. The DMSID that identifies the GCR stream shall be included in the DMS Descriptor. Each Status field in the DMS Status fields included in the frame shall be set to “GCR Advertise.”
- Transmitting unsolicited DMS Response frames with the current settings individually addressed to each GCR group member. Each GCR stream is identified by the DMSID in a DMS Status field in the DMS Response element of the DMS Response frame. These DMS Status fields shall not include a TCLAS element, TSPEC element, or GCR subelement. Each Status field in the DMS Status fields included in the frame shall be set to “GCR Advertise.”

A STA receiving GCR frames shall recover from missing group addressed DMS Response frames containing GCR Response subelements that advertise a changed retransmission policy or delivery method according to Table 11-13 or Table 11-14, respectively.

Table 11-13—STA recovery procedures for a changed retransmission policy

| Current retransmission policy state at STA receiving GCR frames | Actual retransmission policy being used by the AP or mesh STA providing GCR service | Recovery procedure |
|--|--|---|
| GCR unsolicited retry or GCR block ack | No-Ack/No-Retry | A STA receiving GCR frames shall cancel the GCR service for the group address by sending a DMS Response frame that contains a DMS Descriptor with the Request Type set to “Remove” when no frames for the group address are received via the GCR service after a period of dot11GCRPolicyChangeTimeout. |

Table 11-13—STA recovery procedures for a changed retransmission policy (continued)

| Current retransmission policy state at STA receiving GCR frames | Actual retransmission policy being used by the AP or mesh STA providing GCR service | Recovery procedure |
|---|---|--|
| DMS | GCR unsolicited retry or GCR block ack | A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to GCR unsolicited retry upon receiving an A-MSDU for the DMS group address concealed via the GCR concealment address. |
| GCR unsolicited retry or GCR block ack | DMS | A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to DMS upon receiving an A-MSDU with the RA field equal to the non-AP STA's individual address and the DA field of the A-MSDU subframe equal to the GCR group address. |
| GCR unsolicited retry | GCR block ack | A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to GCR block ack upon receiving a BlockAckReq frame with a GCR Group Address subfield equal to the GCR group address. |
| GCR block ack | GCR unsolicited retry | A STA receiving GCR frames shall update its current retransmission policy of the GCR stream to GCR unsolicited retry if MSDUs for the GCR group address concealed via the GCR concealment address are being received yet no BlockAckReq frames for the GCR group address are received after a period of dot11GCRPolicyChangeTimeout. |

Table 11-14—Non-AP STA recovery procedures for a changed delivery method

| Current delivery method state at non-AP STA | Actual delivery method being used by the AP | Recovery procedure |
|---|---|---|
| Non-GCR-SP | GCR-SP | <p>A non-AP STA shall update the current delivery method state of the GCR stream to GCR-SP if</p> <ul style="list-style-type: none"> a) No frames with the More Data subfield in the Frame Control field equal to 1 for the GCR stream are received for a period of dot11GCRPolicyChangeTimeout, and b) At least one frame for the GCR stream with the More Data subfield in the Frame Control field equal to 0 is received. <p>Note that upon detecting condition a), the STA should enter the awake state in order to assist with detecting condition b).</p> |
| GCR-SP | Non-GCR-SP | <p>A non-AP STA shall update the current delivery method of the GCR stream to Non-GCR-SP if no frames with the More Data subfield in the Frame Control field equal to 0 for the GCR stream are received for a period of dot11GCRPolicyChangeTimeout and at least one frame for the GCR stream with the More Data subfield in the Frame Control field equal to 1 is received.</p> |

A GCR agreement between a non-AP STA and an AP or between peer mesh STAs shall end (as described in 11.24.16.2) when one of the following situations occurs:

- In an infrastructure BSS, the AP deauthenticates or disassociates the non-AP STA, or
- In a mesh BSS, the mesh STA providing GCR service tears down the peer link to the mesh STA receiving GCR frames, or
- The non-AP STA or mesh STA receiving GCR frames successfully transmits a DMS Request frame to the AP or mesh STA providing GCR service containing a DMS Request element that has a DMS Descriptor with the DMSID identifying the group addressed stream and the Request Type field set to “Remove,” or
- The AP or a mesh STA providing GCR service successfully transmits an individually addressed DMS Response frame with a DMS Response element containing a DMS Status field with the DMSID identifying the group addressed stream that has the Status field set to “Terminate.”

A GCR agreement between a non-AP STA and an AP or between peer mesh STAs shall end (as described in 11.24.16.2) with the following modifications:

- The DMS Status field shall include a GCR Response subelement.
- The DMS Response frame may be transmitted by an AP to the GCR concealment address or as an individually addressed frame to each STA that has an active GCR agreement for this GCR group address. The DMS Response frame shall be transmitted by a non-AP STA or mesh STA as an individually addressed frame to the STA that it has an active GCR agreement for this GCR group address.

A cancellation of a GCR agreement shall also cause the block ack agreement to be canceled for the GCR stream.

11.24.16.3.5 Concealment of GCR transmissions

Concealment prevents group addressed frames transmitted via the GCR unsolicited retry or GCR block ack retransmission policies from being passed up through the MAC SAPs of GCR-incapable STAs.

GCR group addressed MSDUs shall be sent in an A-MSDU when

- Retransmitted via the GCR unsolicited retry or GCR block ack retransmission policies or
- Transmitted via the GCR-SP delivery method.

The MPDU containing this A-MSDU shall have the Address 1 field set to dot11GCRConcealmentAddress and the Retry subfield of the Frame Control field set to 1. The DA field in the A-MSDU subframe shall contain the GCR group address that is being concealed (i.e., the same value as the DA field for non-GCR group addressed delivery). One A-MSDU subframe shall be contained within one A-MSDU frame. GCR group addressed MSDUs retransmitted via the GCR unsolicited retry or GCR block ack retransmission policies shall set the Sequence Control field of the MPDU containing this A-MSDU to the same value as the Sequence Control field of the frame that contained the corresponding MSDU that was transmitted with the Retry subfield equal to 0. The first transmission attempt of a GCR group addressed MSDU transmitted via the GCR-SP delivery method shall set the Sequence Control field of the MPDU containing this A-MSDU according to the procedures defined in 10.3.2.11.

A STA with dot11RobustAVStreamingImplemented true or dot11MeshGCRImplemented true shall not use its GCR concealment address for any purpose other than the transmission of GCR streams.

A STA with dot11RobustAVStreamingImplemented true or dot11MeshGCRImplemented true and with a GCR agreement shall add the GCR concealment address from the GCR Response subelement to the STA’s dot11GroupAddressesTable.

An AP with dot11RobustAVStreamingImplemented true shall not send an MSDU to the DS that has the DA field set to the GCR concealment address.

The Individual/Group Address bit (LSB of octet 0) of dot11GCRConcealmentAddress shall be set to 1.

11.24.16.3.6 GCR unsolicited retry

A STA supports the GCR unsolicited retry retransmission policy if dot11RobustAVStreamingImplemented or dot11MeshGCRImplemented is true; otherwise, the STA does not support the GCR service with retransmission policy equal to GCR unsolicited retry.

An AP or a mesh STA adopting the GCR unsolicited retry retransmission policy for a GCR group address chooses a lifetime limit for the group address. The AP or a mesh STA may vary the lifetime limit for the group address at any time and may use different lifetime limits for different GCR group addresses. An AP adopting the GCR unsolicited retry retransmission policy for a GCR group address shall transmit each MSDU according to 11.24.16.3.5, subject to the lifetime and retry limits. Transmission uses the backoff procedure described in 10.22.2.11.2.

If a block ack agreement has successfully been established for a group addressed stream that is delivered using the GCR unsolicited retry retransmission policy, the STA shall follow the duplicate detection procedures defined in 10.3.2.11 and 10.24.4.

If a block ack agreement has successfully been established for all STAs receiving a GCR group address, for a group delivered using the GCR unsolicited retry retransmission policy, the AP may retransmit any of the last m A-MSDUs that have the DA field in the A-MSDU subfield set to the GCR group address, where m is GCR buffer size (as defined in 11.24.16.3.7), subject to the lifetime limits.

If there is a STA with an active GCR agreement for a group address that does not have an active block ack agreement, the AP shall not retransmit a preceding A-MSDU for that group address. A preceding A-MSDU is defined as an A-MSDU with a sequence number value that precedes, using the modulo 2^{12} rules defined in 10.24.1, the sequence number value of the last transmitted A-MSDU for the GCR group address.

11.24.16.3.7 GCR block ack

A STA supports the GCR block ack retransmission policy if dot11AdvancedGCRImplemented is true or dot11MeshGCRImplemented is true; otherwise, the STA does not support the GCR service with retransmission policy equal to GCR Block Ack.

The AP shall maintain a set of the most recently received values of the Buffer Size subfield from the Block Ack Parameter Set field in the ADDBA Response frame received from each member of a specific group address. The minimum of that set of values is defined to be the *GCR buffer size* for that group address (see 10.24.10).

11.24.16.3.8 GCR-SP

The GCR-SP delivery method transmits GCR group addressed frames at intervals that might be smaller than the beacon interval.

A STA supports the GCR-SP delivery method if dot11AdvancedGCRImplemented is true; otherwise, the STA does not support the GCR service with the delivery method equal to GCR-SP.

NOTE—Group addressed traffic transmitted at the end of a DTIM beacon might be an impediment to providing QoS for uplink transmissions and in OBSSs. Therefore, APs in an overlapped environment are advised to make use of GCR-SP for group addressed traffic that consumes appreciable medium time.

Group addressed MSDUs shall not be transmitted via the GCR-SP delivery method policy if a non-GCR-SP delivery method is active for that group address.

All MSDUs transmitted via the GCR-SP delivery method shall be concealed using the procedures described in 11.24.16.3.5. A STA receiving group addressed MSDUs transmitted via the GCR-SP delivery method shall discard all nonconcealed MSDUs for this group address.

An AP advertises that a group addressed stream is subject to GCR-SP within a GCR Response subelement. The subelement indicates the start of each SP. See 11.2.3.5. When the Service Interval field in the Schedule element of the DMS Response frame is greater than 0, at every scheduled SP, the AP schedules for transmission buffered GCR-SP group addressed frames assigned to that particular group address.

An AP shall not establish both a GCR-SP and an FMS agreement for a group addressed stream with a single non-AP STA.

An AP may use the GCR-SP delivery method for an accepted GCR service when all of the non-AP STAs that requested the GCR service for the group address have the Robust AV Streaming bit in the Extended Capabilities element equal to 1 and the Advanced GCR bit in the Extended Capabilities element equal to 1. Otherwise, the AP shall not use the GCR-SP delivery method for the accepted GCR service.

When the Service Interval field in the Schedule element of the DMS Response frame is 0, the AP may transmit group addressed frames that are subject to this GCR agreement at any time without regard to the power state of non-AP STAs in the group. This delivery method is called *GCR-A*, where all members of the group need to stay in the awake state to receive these group addressed frames.

11.24.17 WNM notification

Implementation of the WNM notification capability is optional for a WNM STA. A STA that implements the WNM notification capability has `dot11WNMNotificationImplemented` equal to true. When `dot11WNMNotificationImplemented` is true, `dot11WirelessManagementImplemented` shall be true. A STA in which `dot11WNMNotificationActivated` is true is defined as a STA that supports WNM notification. The STA shall set to 1 the WNM Notification field of the Extended Capabilities elements that it transmits.

A STA that supports WNM notification reporting may send a WNM Notification Request or Response frame to a STA within the same infrastructure BSS or the same IBSS whose last received Extended Capabilities element contained a value of 1 for the WNM Notification field in the Extended Capabilities field; it shall not send a WNM Notification Request or Response frame otherwise.

A STA shall transmit both the WNM Notification Request frame and the WNM Notification Response frame with an individually addressed destination address.

The WNM notification capability enables a STA to indicate management information, including information about its firmware to a peer STA. Use of the information provided is outside the scope of this standard. A non-AP STA that supports WNM notification and receives a WNM Notification Request frame with the Type field equal to 0 shall respond with a WNM Notification Response frame with the Response Status field set to 0.

11.25 WLAN interworking with external networks procedures

11.25.1 General

This subclause describes the actions and the procedures that provide interworking capabilities between IEEE 802.11 infrastructure and external networks.

11.25.2 Interworking capabilities and information

STAs indicate their support for interworking service by setting dot11InterworkingServiceActivated to true. When dot11InterworkingServiceActivated is true, STAs include the Interworking element in Beacon and Probe Response frames, and non-AP STAs include the Interworking element in Probe Request frames.

When dot11InterworkingServiceActivated and dot11ExtendedChannelSwitchActivated are both true in an infrastructure BSS, the AP may provide its operating channel and operating class to an Interworked SSPN using the values from dot11OperatingClassesTable.

In an infrastructure BSS, the Interworking element contains signaling for Homogeneous ESSs. The HESSID is a 6-octet MAC address that identifies the homogeneous ESS. The HESSID value shall be identical to one of the BSSIDs in the homogeneous ESS. Thus, it is a globally unique identifier that, in conjunction with the SSID, may be used to provide network identification for an SSPN.

NOTE—This standard assumes that the HESSID field in the Interworking element is administered consistently across all BSSs in a homogeneous ESS.

The Interworking element also provides an access network type in Beacon and Probe Response frames to assist the non-AP STA with network discovery and selection.

11.25.3 Interworking procedures: generic advertisement service (GAS)

11.25.3.1 Introduction

This subclause describes the actions and procedures that are used to invoke GAS. GAS may be used to enable network selection for STAs when dot11InterworkingServiceActivated is true. GAS provides transport mechanisms for advertisement services while STAs are in the unassociated state as well as the associated state. This is accomplished via the use of Public Action frames, which are Class-1 frames. GAS information shall be transmitted using individually addressed Public Action frames. When management frame protection is negotiated, stations shall use individually addressed Protected Dual of Public Action frames instead of individually addressed Public Action frames.

A GAS frame exchange may take place between two STAs; one STA transmits a GAS Query Request and the other STA transmits the GAS Query Response as described in 11.25.3.2. The Advertisement Protocol transported by the GAS is one of the query protocols in Table 9-215.

GAS shall be supported by a STA when dot11InterworkingServiceActivated is true. ANQP shall be supported by a STA when dot11InterworkingServiceActivated is true. Other advertisement protocols shall be supported when the corresponding dot11GASAdvertisementID is present.

A STA shall not transmit a GAS Query for any Advertisement Protocol unless that Advertisement Protocol ID is included in the Advertisement Protocol element in a Beacon or Probe Response frame. The Advertisement Protocol element specifies the Advertisement Protocols that a STA may use to communicate with Advertisement Servers, which may be collocated with a STA or in an external network. The Advertisement Protocol identifies the query language used by the Advertisement Server. The GAS protocol, which is used to transport Queries and Query Responses, is transparent to the Advertisement Protocol.

11.25.3.2 GAS Protocol

11.25.3.2.1 General

The presence of the Interworking element in Beacon or Probe Response frames indicates support for the GAS protocol. The presence of the Advertisement Protocol element in Beacon or Probe Response frames indicates the Advertisement Protocol IDs supported in the BSS or IBSS. A STA transmits a GAS Query Request in a GAS Initial Request frame and the responding STA provides the GAS Query Response or information on how to receive the GAS Query Response in a GAS Initial Response frame. The GAS Query Response shall be delivered in a single GAS Initial Response frame or in one or more GAS Comeback Response frames; the GAS Query Response shall not be split between a GAS Initial Response frame and one or more GAS Comeback Response frames. The GAS message sequence diagrams are shown in Figure 11-38, Figure 11-39, and Figure 11-40.

Figure 11-38 describes the GAS frame exchange sequence when `dot11GASPauseForServerResponse` is true and the result of the GAS query fits within one MMPDU.

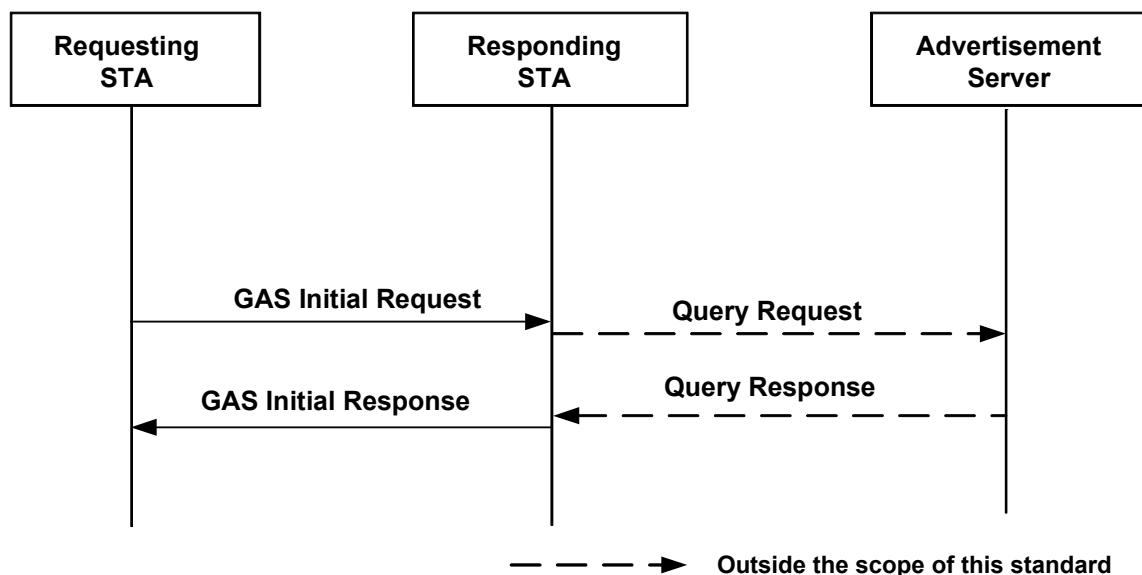

Figure 11-38—GAS frame sequence with `dot11GASPauseForServerResponse` equal to true

Figure 11-39 describes the GAS frame exchange sequence when `dot11GASPauseForServerResponse` is true and the result of the GAS query is too large to fit in one MMPDU and GAS fragmentation is used for delivery. The number of GAS Comeback Request and GAS Comeback Response frames depends on the number of GAS fragments required for delivery of the result of the GAS query.

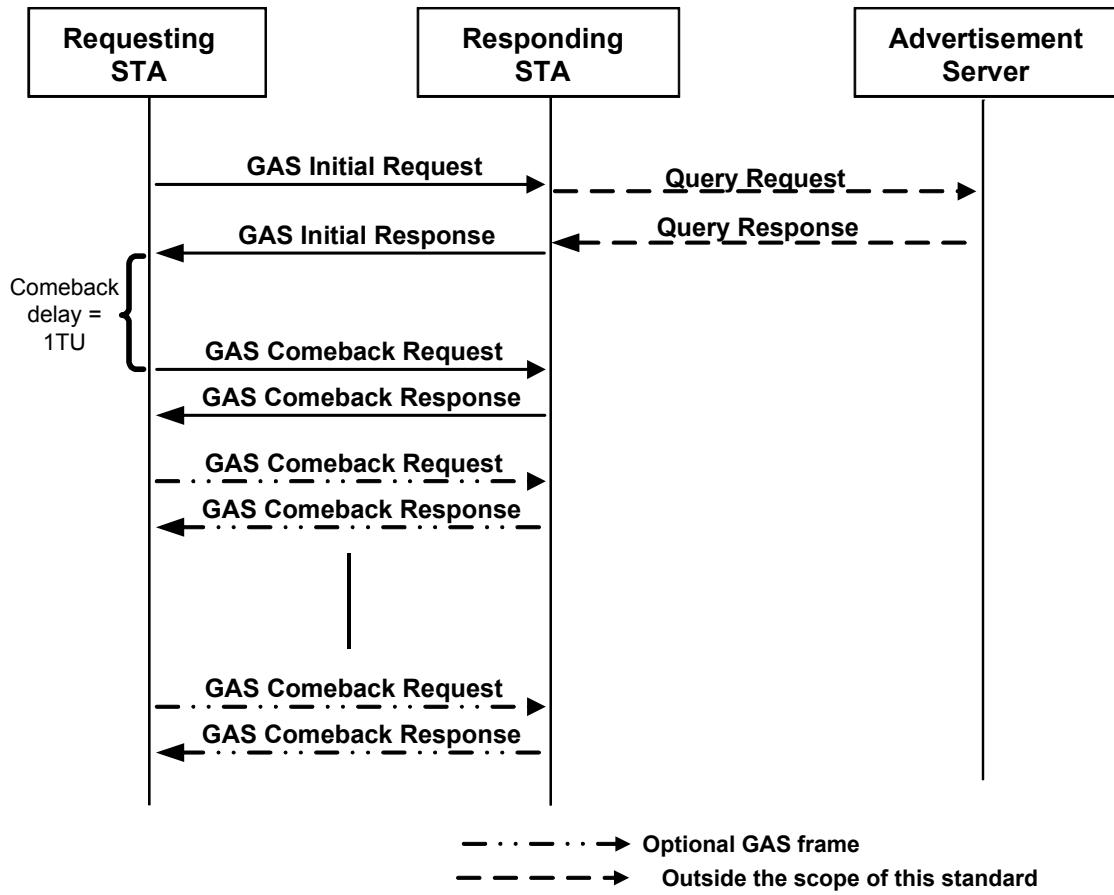

Figure 11-39—GAS frame sequence with GAS fragmentation and dot11GASPauseForServerResponse equal to true

Figure 11-40 describes the GAS frame exchange sequence when `dot11GASPauseForServerResponse` is false. The number of GAS Comeback Request and GAS Comeback Response frames depends on the number of GAS fragments required for delivery of the GAS Query Response.

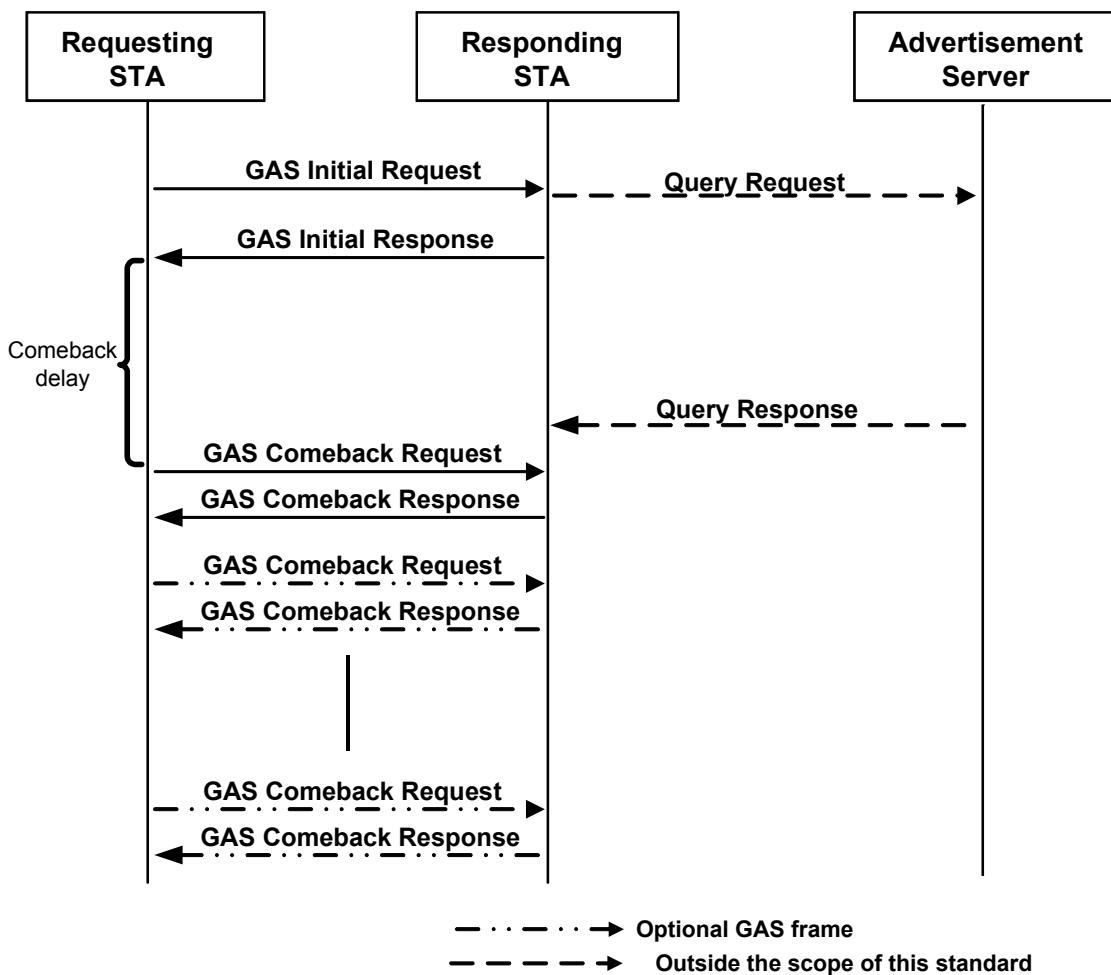

Figure 11-40—GAS frame sequence with GAS fragmentation and dot11GASPauseForServerResponse equal to false

11.25.3.2.2 STA procedures to transmit a GAS Query

Upon receipt of an MLME-GAS.request primitive, the requesting STA shall engage in the following procedure to transmit a query:

- a) The requesting STA sends a GAS Query by transmitting a GAS Initial Request frame containing a Dialog Token, an Advertisement Protocol element containing an Advertisement Protocol ID and the GAS Query in the Query Request field. If the GAS Initial Request frame requests information relating to a frequency band different from the frequency band in which the frame is transmitted, the STA shall include a Multi-band element in the GAS Initial Request frame with the Band ID, Operating Class, and Channel Number fields set to indicate to which frequency band the GAS Initial Request frame applies, with other fields in the Multi-band element being reserved. If the frame requests information relating to the frequency band in which the frame is transmitted, a Multi-band element shall not be included in the frame.

- b) Upon transmission of the GAS Initial Request frame, the STA shall set a timer, referred to as the *dot11GASResponseTimer*, equal to *dot11GASResponseTimeout* or the *QueryFailureTimeout* parameter provided in the MLME-GAS.request primitive. If both values are present, the timer shall be set to the lesser of the two values.
- c) If the requesting STA is not in the associated state, it shall remain in active mode until the receipt of a GAS Initial Response frame with the same value of the Dialog Token field as in the GAS Initial Request frame or until the expiration of the timer, whichever occurs first. If the requesting STA is in the associated state, it may go into power save state until the GAS Initial Response frame is available for receipt or the timer expiration, whichever occurs first.
- d) If the *dot11GASResponseTimer* expires before a GAS Initial Response frame is received, the GAS Query was not successful and the MLME shall issue an MLME-GAS.confirm primitive with ResultCode equal to *GAS_QUERY_TIMEOUT* and shall set the Query Response Length field to 0.

11.25.3.2.3 STA procedures to post a GAS Query to an Advertisement Server

Upon receipt of a GAS Initial Request frame, an MLME-GAS.indication primitive shall be issued to the STA's SME. Upon receipt of an MLME-GAS.response primitive, the STA shall transmit a GAS Initial Response frame to the requesting STA according to the following procedures. If the requesting STA is in the associated state and in the power save mode, the responding STA shall buffer the MMPDU for transmission according to the procedures in 11.2.3; otherwise the STA shall queue the MMPDU for transmission as follows:

- a) If the Advertisement Protocol ID in the Advertisement Protocol element does not equal the value contained in any *dot11GASAdvertisementID*, then the STA shall not post the query to an Advertisement Server. The STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code equal to *GASADVERTISEMENT_PROTOCOL_NOT_SUPPORTED* (see Table 9-46), an Advertisement Protocol element containing the Advertisement Protocol ID used in the GAS Initial Request frame and a Comeback Delay and Query Response Length both set to 0.
- b) If the query request corresponds to an Advertisement Protocol whose server is currently unreachable, the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code equal to *SERVER_UNREACHABLE*, an Advertisement Protocol element containing an Advertisement Protocol ID equal to the Advertisement Protocol ID contained in the GAS Initial Request frame and a Comeback Delay and Query Response Length both set to 0. The method used by the AP to determine the server is unreachable is out of scope of this standard. A STA receiving a status code indicating *SERVER_UNREACHABLE* should wait at least 1 minute before transmitting any further queries using the same Advertisement Protocol ID to the responding STA.
- c) If the Advertisement Protocol ID in the Advertisement Protocol element equals the value contained in any *dot11GASAdvertisementID*, then the STA shall initialize a timer, referred to as the *PostReplyTimer*, to the value in *dot11GASResponseTimeout* and post the query to the Advertisement Server identified by the Advertisement Protocol ID. The methods and protocols the STA uses to post the query are outside the scope of this standard.
- d) If *dot11GASPauseForServerResponse* is false, the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code set to *SUCCESS*, an Advertisement Protocol element containing the Advertisement Protocol ID used in the GAS Initial Request frame, a GAS Comeback Delay set to the value in *dot11GASComebackDelay* for this Advertisement Protocol and a Query Response Length set to 0.
- e) If *dot11GASPauseForServerResponse* is true, the GAS Query Response is delivered as defined in 11.25.3.2.4.

11.25.3.2.4 STA procedures for transmitting the GAS Query Response

After receiving a query response from the Advertisement Server, the responding STA shall buffer the query response for a minimum of dot11GASResponseBufferingTime after the expiration of the GAS Comeback Delay or until the query response is delivered. If the responding STA does not receive a GAS Comeback Request frame whose source MAC address and dialog token match the source MAC address and value of the Dialog Token field respectively of the corresponding GAS Initial Response frame within this time, it may drop the query response. If the query response received from the Advertisement Server is larger than dot11GASQueryResponseLengthLimit for the matching dot11GASAdvertisementID or is larger than the value of the Query Response Length Limit field received from the requesting STA, the responding STA shall discard the response and instead return a status code of GAS_QUERY_RESPONSE_TOO_LARGE in the GAS Comeback Response frame. This behavior helps to prevent abuses of the medium that may be caused by overly general queries, which evoke a very large query response.

The GAS protocol supports Query Responses whose length is greater than the IEEE 802.11 maximum MMPDU size by the STA's use of the GAS Query Response Fragment ID field in the GAS Comeback Response frame; the Query Response Fragment ID shall be set to 0 for the initial fragment and incremented by 1 for each subsequent fragment in a multi-fragment query response. If the Query Response is a multi-fragment response (i.e., contains more than 1 fragment), the STA shall transmit all fragments that belong to the same Query Response until all fragments are exhausted. The STA shall set the More GAS Fragments field of the GAS Query Response Fragment ID to 0 when the transmitted fragment is the final fragment.

If the GAS Initial Request frame that initiated the GAS transaction contains a Multi-band element, but the GAS Initial Response frame transmitted as a response does not contain a copy of the same Multi-band element, the Status Code in the GAS Initial Response frame shall be set to REQUEST_DECLINED. Otherwise, the requesting and responding STAs shall include a copy of the same Multi-band element in all subsequent GAS Initial Response, GAS Comeback Request, and GAS Comeback Response frames transmitted as part of the GAS transaction. Inclusion of the Multi-band element indicates to which frequency band the GAS transaction applies. If the GAS Initial Request frame that initiated the GAS transaction does not contain a Multi-band element, then none of the subsequent GAS Initial Response, GAS Comeback Request, and GAS Comeback Response frames transmitted as part of the GAS transaction shall include a Multi-band element.

The following procedures shall be used by the responding STA to deliver the query response to the requesting STA:

- a) If dot11GASPauseForServerResponse is true:
 - 1) If the PostReplyTimer expires before the GAS Query Response is received from the Advertisement Server, then the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code set to GAS_QUERY_TIMEOUT (see Table 9-46), an Advertisement Protocol element containing the Advertisement Protocol ID used in the GAS Initial Request frame, a GAS Comeback Delay set to 0 and a Query Response Length set to 0. If the query response is subsequently received from the Advertisement Server, it shall be dropped by the responding STA.
 - 2) If the Query Response received from the Advertisement Server is larger than dot11GASQueryResponseLengthLimit or requires more than 128 fragments for transmission to the requesting STA, it shall be dropped by the responding STA. Then the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code set to GAS_QUERY_RESPONSE_TOO_LARGE (see Table 9-46), an Advertisement Protocol element containing the Advertisement Protocol ID used in the GAS Initial Request frame, a GAS Comeback Delay set to 0 and a Query Response Length set to 0.

- 3) If the query response's length is less than or equal to the maximum MMPDU size, the STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code set to SUCCESS, an Advertisement Protocol element containing the Advertisement Protocol ID used in the GAS Initial Request frame, a GAS Comeback Delay set to 0, the Query Response and a Query Response Length set to the query response length. This completes the GAS Query and GAS Query Response exchange.
- 4) If the query response's length is larger than the maximum MMPDU size, the responding STA shall transmit an individually addressed GAS Initial Response frame to the requesting STA containing a dialog token whose value is identical to the dialog token in the GAS Initial Request frame, a Status Code set to SUCCESS, an Advertisement Protocol element containing the Advertisement Protocol ID used in the GAS Initial Request frame, a GAS Comeback Delay set to 1 TU, and a Query Response Length set to 0; this indicates the query response will be transmitted using GAS Comeback Request and Response frames that support GAS fragmentation as follows.
 - b) If dot11GASPauseForServerResponse is false:
 - 1) If the PostReplyTimer expires before the GAS Query Response is received from the Advertisement Server then the responding STA shall buffer for transmission a GAS Comeback Response frame with a status code equal to GAS_QUERY_TIMEOUT (see Table 9-46). If the query response is subsequently received from the Advertisement Server, it shall be dropped by the STA.
 - 2) If the Query Response received from the Advertisement Server is larger than dot11GASQueryResponseLengthLimit, it shall be dropped by the responding STA. Then the STA shall buffer for transmission a GAS Comeback Response frame with status code set to GAS_QUERY_RESPONSE_TOO_LARGE.
 - c) If the Query Response is received before the expiration of the PostReplyTimer and its length is less than dot11GASQueryResponseLengthLimit, then the Query Response shall be buffered in one or more GAS Comeback Response frames with status code set to SUCCESS. The responding STA transmits one GAS Comeback Response frame in response to each GAS Comeback Request frame. If the Query Response received from the Advertisement Server is less than or equal to the maximum MMPDU size, then the GAS Query Response Fragment ID shall be set to 0 and the More GAS Fragments field in the GAS Query Response Fragment ID shall be set to 0. If the Query Response received from the Advertisement Server is greater than the maximum MMPDU size, then the GAS Query Response Fragment ID shall be set to 0 if this is the first fragment of the Query Response transmitted; otherwise it shall be incremented by 1; the More GAS Fragments field in the GAS Query Response Fragment ID shall be set to 1 if there are more fragments of the Query Response to be transmitted; otherwise it shall be set to 0 (i.e., this fragment is the last fragment of the Query Response).
 - d) If a responding STA receives a GAS Comeback Request frame whose source MAC address and dialog token match the destination MAC address and value of the Dialog Token field respectively of an outstanding GAS Initial Response frame and the query response has not been received from the Advertisement Server and the PostReplyTimer has not expired, the responding STA shall transmit a GAS Comeback Response frame with status code equal to GAS_RESPONSE_NOT_RECEIVED_FROM_SERVER (see Table 9-46) and GAS Comeback Delay set to the value in dot11GASComebackDelay for this Advertisement Protocol to indicate when the requesting STA should come back to obtain its Query Response.
 - e) If a responding STA receives a GAS Comeback Request frame whose source MAC address and Dialog Token do not match the destination MAC address and value of the Dialog Token field respectively of an outstanding GAS Initial Response frame, the STA should transmit a GAS Comeback Response frame with a status code equal to NO_OUTSTANDING_GAS_REQUEST.

A requesting STA shall transmit a GAS Comeback Request frame including the Dialog Token (drawn from the corresponding GAS Initial Response frame) immediately after the expiration of the GAS Comeback Delay. In response, the responding STA provides the Query Response in one or more GAS Comeback Response frames with the corresponding Dialog Token.

If a requesting STA receives a GAS Comeback Response frame with status equal to QUERY_RESPONSE_OUTSTANDING, the requesting STA shall wait for the GAS Comeback Delay from that frame and upon expiration of the GAS Comeback Delay, transmit another GAS Comeback Request frame. If the requesting STA's dot11GASResponseTimer (set in 11.25.3.2.2 step b) expires prior to receiving a GAS Comeback Response frame whose source MAC address and dialog token match those in the corresponding GAS Initial Response frame, the STA shall issue an MLME-GAS.confirm primitive with ResultCode equal to GAS_QUERY_TIMEOUT and shall set the Query Response Length to 0.

If a requesting STA receives a GAS Comeback Response frame with status equal to SUCCESS and the More GAS Fragments field in the GAS Query Response Fragment ID equal to 1, it shall transmit another GAS Comeback Request frame in order to retrieve the next GAS fragment of a multi-fragment query response.

If a requesting STA receives a GAS Comeback Response frame with status equal to SUCCESS and the More GAS Fragments field in the GAS Query Response Fragment ID equal to 0, the requesting STA's MLME shall determine that all fragments have been received by confirming that all fragment IDs from 0 to the value in the GAS Query Response Fragment ID when the More GAS Fragments field was equal to 0 have been received. Upon receipt of the first GAS Comeback Response frame and every GAS Comeback Response frame thereafter, the dot11GASResponseTimer shall be reset. If all of the query response fragments were received before the expiration of the dot11GASResponseTimer, then the MLME shall issue an MLME-GAS.confirm primitive with result code set to SUCCESS along with the query response. If not all of the query response fragments were received before the expiration of the dot11GASResponseTimer, then the MLME shall issue an MLME-GAS.confirm primitive with ResultCode equal to GAS_QUERY_TIMEOUT and shall set the Query Response Length to 0.

After a requesting STA receives the first GAS fragment of a multi-fragment query response, it shall continue retrieving the query response until all GAS fragments are received or until a transmission failure is detected; the requesting STA shall not commence the retrieval of a another GAS Query Response from the same STA until all GAS fragments are received or until a transmission failure is detected on the first GAS Query Response.

If a requesting STA receives a GAS Comeback Response with status equal to GAS_QUERY_TIMEOUT or GAS_QUERY_RESPONSE_TOO_LARGE then the MLME shall issue an MLME-GAS.confirm primitive with result code so indicating and shall set the Query Response Length to 0.

If a requesting STA receives a GAS Comeback Response with status equal to NO_OUTSTANDING_GAS_REQUEST, then the MLME shall issue an MLME-GAS.confirm primitive with result code set to NO_OUTSTANDING_GAS_REQUEST and shall set the Query Response Length to 0.

11.25.3.2.5 GAS procedures interaction with multiple BSSID set

Non-AP STAs in the unassociated state may use GAS procedures to query Advertisement Servers for information. As described in 11.25.3.2, APs indicate their support for a particular GAS Advertisement Protocol by including an Advertisement protocol element with that Advertisement protocol ID in Beacon and Probe Response frames as described in 9.3.3.3 and 9.3.3.11 respectively. Non-AP STAs receiving Beacon or Probe Response frames from different APs may choose to engage in GAS frame exchange sequences with one or more of these APs. In some deployment scenarios, these APs may be operating as a multiple BSSID set (as defined in 11.11.14) and may relay the GAS queries to the same Advertisement

Server. Depending on the configuration of the IEEE 802.11 access network, the external network and the Advertisement Server, a query response from the Advertisement Server might or might not be dependent on the BSSID used in the GAS frame exchange sequence and thus the STA from which the query was relayed. If the GAS Query Response is dependent on the BSSID, a requesting STA may choose to post queries using GAS procedures to more than one STA and expect possibly different Query Responses. If the Query Response is not dependent on the BSSID, then a requesting STA may choose to post queries using GAS procedures to only one STA in the multiple BSSID set (i.e., posting the same query to another member of the multiple BSSID set would yield the same response).

When a Multiple BSSID (as defined in 11.11.14) set contains two or more members and dot11InterworkingServiceActivated is true and dot11GASAdvertisementID is present and a query to the Advertisement Server corresponding to dot11GASAdvertisementID is not dependent on the BSSID value used in the GAS frame exchange sequence to post the query, then the PAME-BI bit in the Advertisement Protocol tuple of the Advertisement Protocol element corresponding to dot11GASAdvertisementID shall be set to 1; otherwise this bit shall be set to 0.

11.25.3.3 ANQP procedures

11.25.3.3.1 General

A STA may use ANQP to retrieve information as defined in Table 9-271 from a peer STA.

A non-AP STA shall not transmit an ANQP request to an AP for any ANQP-element unless the ANQP Advertisement Protocol ID is included in the Advertisement Protocol element in a Beacon or Probe Response frame from that AP.

The ANQP request consists of one or more ANQP elements drawn from Table 9-271 having an element type of Q in Table 11-15 and shall be ordered by nondecreasing Info ID. A Query List ANQP-element included in an ANQP request is formed as described in 11.25.3.2.2. The ANQP request is transported in the Query Request field of GAS Request frames as described in 11.25.3.2.4.

The ANQP response should consist of ANQP elements having Info IDs present in the Query List ANQP-element response (if present) plus zero or more responses to other query elements; these ANQP elements shall be chosen from among those listed in Table 9-271 having an element type of S in Table 11-15 and shall be ordered by non-decreasing Info ID. The ANQP response is transported in the Query Response field of GAS Response frames, as described in 11.25.3.2.4.

Table 11-15—ANQP usage

| ANQP-element name | ANQP-element (subclause) | ANQP-element type | BSS | | IBSS |
|-----------------------------|--------------------------|-------------------|------|------------|------|
| | | | AP | Non-AP STA | STA |
| Query List | 9.4.5.2 | Q | T, R | T, R | T, R |

| Advice of Charge | 9.4.5.21 | S | T | T | — |
| Local Content | 9.4.5.22 | S | T | T | — |
| Network Authentication Type with Timestamp | 9.4.5.23 | S | T | R | — |
| Symbols | | | | | |
| Q | element is an ANQP request | | | | |
| S | element is an ANQP response | | | | |
| T | ANQP-element may be transmitted by MAC entity | | | | |
| R | ANQP-element may be received by MAC entity | | | | |
| — | ANQP-element is neither transmitted nor received by MAC entity | | | | |

ANQP usage for infrastructure BSSs and IBSSs shall be in accordance with Table 11-15. ANQP usage defines the entities permitted to transmit and receive particular ANQP-elements.

A STA having dot11InterworkingServiceActivated equal to true shall be capable of using the Query List ANQP-element to request the Capability List ANQP-element; support for all other ANQP-elements is optional.

A STA that encounters an unknown or reserved ANQP Info ID value in a GAS frame (see 9-307) received without error shall ignore that ANQP Info ID and shall parse any remaining ANQP Info IDs.

A STA that encounters an unknown vendor-specific OI field or subfield in a GAS frame (see 9-307) received without error shall ignore that field or subfield respectively, and shall parse any remaining fields or subfields for additional information with recognizable field or subfield values.

11.25.3.3.2 Query list procedure

The Query List ANQP-element is used by a requesting STA to perform an ANQP request using the procedures defined in 11.25.3.3.1. The requesting STA may include Info IDs in the Query List ANQP-element that have the sole ANQP-element type of S as shown in Table 11-15; the STA shall not include other Info IDs.

A responding STA that encounters an unknown or reserved ANQP Info ID value in an Query List ANQP-element received without error shall ignore that ANQP Info ID and shall parse any remaining ANQP Info IDs.

11.25.3.3.3 Roaming Consortium procedure

The Roaming Consortium ANQP-element, which contains a set of OIs, can be retrieved from an AP by a non-AP STA using the query list procedure defined in 11.25.3.3.2. The list of OIs included in the Roaming Consortium ANQP-element shall be those OIs in the dot11RoamingConsortiumTable. An AP may include an OI in the dot11RoamingConsortiumTable, if in conjunction with an AS, it is capable of successfully authenticating a non-AP STA having valid security credentials for the SSPN identified by that OI; the AP shall not include an OI otherwise. Methods used by the AP to authenticate the non-AP STA include, but are not limited to, RSNA algorithms and Open System authentication.

Each OI identifies an SSP or group of SSPs (i.e., a roaming consortium). An SSP or group of SSPs can register for and obtain an OI using the procedures described in [B19].

A non-AP STA might have a locally stored binding between an OI and a set of security credentials with which it can authenticate to the network identified by the OI, that is, the SSPN. The method by which this binding is obtained is outside the scope of this standard. A non-AP STA can select from that list of credentials when authenticating to the BSS.

11.25.3.3.4 AP procedure for advertising EAP Method associated with an NAI Realm

When dot11RSNAActivated is true, NAI realms along with their supported authentication methods may be advertised using the NAI Realm ANQP-element (see 9.4.5.10). Each realm may be optionally associated with a set of EAP methods. Each EAP method may be optionally associated with a set of Authentication Parameters. The NAI realm ANQP-element provides a hint on the methods a STA might use to establish an association in an RSN IEEE 802.1X environment. If the non-AP STA recognizes the NAI realm, it may attempt authentication even if it believes the EAP methods are incorrect.

When dot11RSNAActivated is false and the Network Authentication Type (see 9.4.5.6) contains a Network Authentication Type Unit having a Network Authentication Type Indicator field equal to http/https redirection or DNS redirection, NAI realms without supported authentication methods may be advertised using the NAI Realm ANQP-element (see 9.4.5.10).

A non-AP STA having dot11InterworkingServiceActivated equal to true may process the NAI Realm ANQP-element. The selection of the NAI realm the non-AP STA uses for authentication is outside the scope of this standard. A non-AP STA requests the NAI Realm ANQP-element using Query List procedures defined in 11.25.3.3.2.

A non-AP STA having dot11InterworkingServiceActivated equal to true may process the EAP Method list as follows:

- The EAP Method list provided by the AP shall be in priority order (the most preferred EAP Method is listed first).
- The credential types help the STA to determine what credentials to use for authentication.

- The STA should confirm the GAS advertisement after an RSNA is established by performing a GAS Query for the NAI Realm ANQP-element using Protected Dual of Public Action frames.

NOTE—The advertisements should be confirmed after the RSNA is established to avoid downgrade attacks.

The policy that determines whether a non-AP STA should attempt authentication and/or association with any particular IEEE 802.11 Access Network is outside the scope of this standard.

11.25.3.3.5 3GPP Cellular Network procedure

A STA may retrieve 3GPP Cellular Network information using the Query List procedure in 11.25.3.3.2. Realms referenced in the 3GPP Cellular Network ANQP-element should not be included in the NAI Realm ANQP-element (see 9.4.5.10).

11.25.3.3.6 AP Geospatial Location procedure

A STA may retrieve an AP's geospatial location using the Query List procedure in 11.25.3.3.2. A STA in the associated state should retrieve Geospatial location information from the AP using the procedures in 11.11.9.6.

11.25.3.3.7 AP Civic Location procedure

A STA may retrieve an AP's civic location using the Query List procedure in 11.25.3.3.2. A STA in the associated state should retrieve civic location information from the AP using the procedures in 11.11.9.9.

11.25.3.3.8 AP Location Public Identifier URI/FQDN procedures

A STA when dot11InterworkingServiceActivated is true may retrieve an AP's Location Public Identifier URI or a location server's FQDN using ANQP procedures in 11.25.3.3. A STA in the associated state should retrieve Location Public Identifier URI/FQDN information from the AP using the procedures in 11.11.9.10.

Due to security concerns, there are some URI schemes that should be cautiously processed when received by a STA. For example, URIs using the scheme names “data.” and “http:” may direct applications (e.g., a browser) on the STA to Internet pages that contain active scripts. Therefore, URIs received via this ANQP procedure should not be processed in a general manner, as these scripts may be inadvertently activated. Instead of listing all of the types of URIs that might be misused or potentially have harmful affects, Section 3.3 IANA registers acceptable URI schemes.

11.25.3.3.9 Emergency NAI procedure

A STA that does not have valid credentials to authenticate to a network may use the information in the Emergency NAI ANQP-element as its EAP identity.

The Emergency NAI ANQP-element can be retrieved from the AP using the Query List procedure in 11.25.3.3.2.

The STA uses the emergency NAI procedure to indicate its intention to access the network without peer authentication by using the emergency NAI information as its identity in the authentication process, as described in IETF RFC 5216.

11.25.3.3.10 TDLS Capability procedure

A STA may use the TDLS Capability ANQP-element (see 9.4.5.18) to discover TDLS capabilities of another TDLS capable STA using the Query List procedure in 11.25.3.3.2.

An example of TDLS capability discovery using ANQP is given in Figure 11-41.

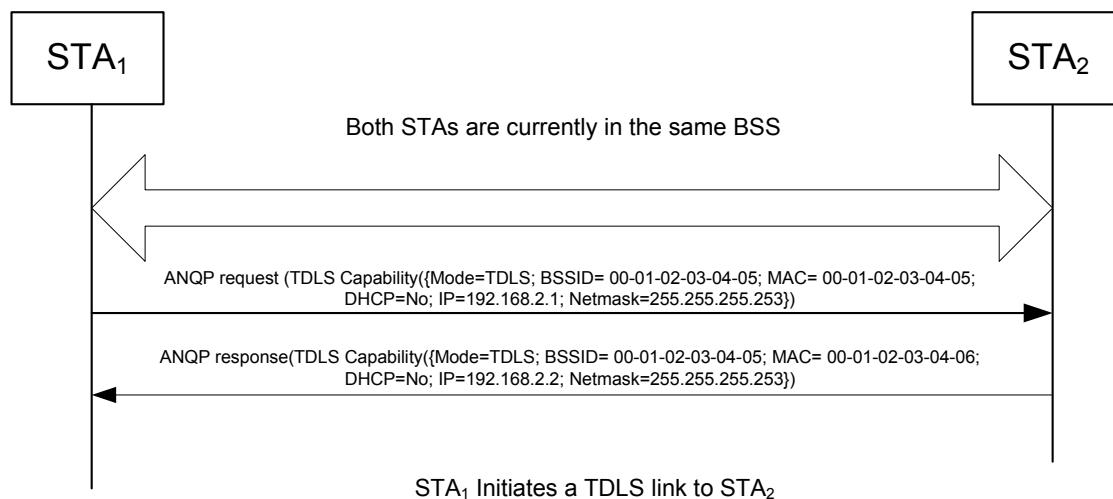

Figure 11-41—Example TDLS Capability discovery using ANQP

The mechanism shall work as follows:

- STA1 determines the MAC address of STA2.
- STA1 sends an ANQP request to STA2. The ANQP request includes a TDLS Capability ANQP-element.
- STA2 receives the ANQP request and updates the TDLS Capability ANQP-element based on its own capabilities that is returned in the ANQP response to STA1.

11.25.3.3.11 Venue URL procedure

The Venue URL ANQP-element is used to provide web page advertising services or information particular to the venue.

This ANQP-element is to be used in conjunction with the Venue Name ANQP-element, to provide extra information about the venue. Typical operation is to use the Venue Name ANQP-element to determine the list of available venues advertised by a STA, and then the Venue URL ANQP-element is used, if required, to determine a list of Venue URLs, each entry corresponding to the Venue Name entry in the list returned by the Venue Name ANQP-element.

11.25.3.3.12 Advice of Charge procedure

The Advice of Charge ANQP-element is used to provide financial cost advertisements in the form of Advice of Charge plan information. The plan information is provided on a per NAI realm basis, so that each authentication realm can advertise the charge associated with obtaining network access. This information might assist with a decision about proceeding with access.

The use and operation of the Plan information schema is outside the scope of this standard.

As ANQP-elements are transmitted in the clear, prior to STA association, one or more protected dual of public action frames should be used after association to verify this information.

11.25.3.3.13 Local Content procedure

The Local Content ANQP-element is used to provide local content URLs. Each URL points to local content information that might be relevant, for example by providing information about terms and conditions for BSS access, when automated login procedures are being used.

Several URLs can be provided in the Local Content ANQP-element, each corresponding to a separate state. This allows the STA to display differing local content (e.g., terms and conditions, failure warning information, help page), through the STA association procedure.

For example, the Local Content ANQP-element may return two Local Content Duple fields with values of the State field corresponding to “Not authenticated” and “Failure during authentication.” The requesting STA may display the contents of the local web page indicated by the first URL (“Not authenticated”) showing terms and conditions of BSS access. If a subsequent association fails, then the requesting STA may display the contents of the local web-page indicated by the second URL (“Failure during authentication”) showing a help page.

11.25.3.4 Registered location query protocol (RLQP) procedures

When dot11GDDActivated is true, a STA may use RLQP to retrieve information as defined in Table 9-215 from a peer STA that has transmitted an Advertisement Protocol element indicating support for RLQP (see 9.4.2.93) in a Beacon or Probe Response frame.

If information is not configured for a particular RLQP-element, then a query for that element returns that element with no optional fields.

When RLQP is transmitted between the GDD enabling STA and the RLSS, it uses Ethertype 89-0d frames, as defined in Annex H. The RLQP payload contains RLQP-elements as specified in 9.4.6 and the Advertising Protocol element with an Advertising Protocol tuple whose Advertisement Protocol ID is set to the value of RLQP specified in Table 9-215. When RLQP is transmitted between the GDD dependent STA and its GDD enabling STA, it uses protected Action frames, but does not use Ethertype 89-0d frames.

In some regulatory domains, the GDD enabling STA may be required to have secured connection with the RLSS. When security is required by regulation, the Ethertype 89-0d frame body may employ corresponding security features. Alternatively, various security protocols may also be selected by setting the Ethertype field to respective values. A webpage maintained by the IEEE Registration Authority Committee allowing search of the public values of the Ethertype field is found at <http://standards.ieee.org/develop/regauth/ethertype/public.html>.

11.25.4 Interworking procedures: IEEE 802.21 MIH support

IEEE Std 802.21-2008, the “MIH standard,” supports handovers across heterogeneous networks. STAs with dot11InterworkingServiceActivated equal to true and dot11GasAdvertisementId equal to MIH Information Service (see Table 9-215) shall support the transmission and reception of IEEE 802.21 MIIS queries for STAs in all states. STAs with dot11InterworkingServiceActivated equal to true and dot11GasAdvertisementId equal to MIH Command and Event Services Capability Discovery (see Table 9-215) shall provide support for IEEE 802.21 MICS/MIES capability discovery for non-AP STAs in all states.

Additionally, support for IEEE 802.21 MIIS query and IEEE 802.21 MICS/MIES capability discovery to non-AP STA’s in the associated state is provided by the STA forwarding IP datagrams destined for the MIH point of service to the IEEE 802.21 MIIS server.

A non-AP STA discovers support for these services by receiving Beacon or Probe Response frames with an Advertisement Protocol element having Advertisement Protocol ID(s) for MIH Information Service and/or IEEE 802.21 MICS/MIES capability discovery.

A non-AP STA forms an IEEE 802.21 IS query by creating its query request according to the procedures defined in IEEE Std 802.21-2008 and formatting that request into an IEEE 802.21 MIH protocol frame as defined in 8.4 of IEEE Std 802.21-2008. The non-AP STA, using the procedures in 11.25.3.2, posts the query to an IEEE 802.21 IS server by transmitting the MIH formatted frame in the Query Request field of a GAS Initial Request frame. The Advertisement Protocol ID field in the GAS Initial Request frame is set to the value of IEEE 802.21 MIH Information Service (Table 9-215).

Non-AP STAs in the unauthenticated or unassociated or associated states can use GAS procedures to discover MIH Command and Event Services Capability as specified in Table 9-215.

A non-AP STA forms an IEEE 802.21 MIH Command and Event Service discovery request by encapsulating an MIH_Capability_Discover request (see IEEE Std 802.21-2008) into an MIH protocol frame as defined in 8.4 of IEEE Std 802.21-2008. The non-AP STA, using the procedures in 11.25.3.2, posts the discovery request to the network by transmitting the MIH formatted frame in the Query Request field of a GAS Initial Request frame. The Advertisement Protocol ID field in the GAS Initial Request frame is set to the value of MIH Command and Event Services Capability Discovery (Table 9-215). The method by which the AP relays the discovery request to the network is defined in IEEE Std 802.21-2008 and is outside the scope of this standard.

A non-AP STA retrieves the IEEE 802.21 MIH Command and Event Service discovery response according to the procedures in 11.25.3.2. The discovery response is an MIH protocol frame as defined in 8.4 of IEEE Std 802.21-2008.

11.25.5 Interworking procedures: interactions with SSPN

11.25.5.1 General operation

To provide SSPN Interface services, the IEEE 802.11 network interacts with the SSPN corresponding to the user of the non-AP STA either directly or via a roaming relationship. As part of setting up the RSN security association, user policies are communicated to the AP. If dot11SSPNInterfaceActivated is true, these permissions shall be stored in the AP's dot11InterworkingTableEntry for that STA. Thereafter, the AP shall use the dot11InterworkingTableEntry for controlling the service provision to that non-AP STA. User policies from the SSPN affect authentication, authorization, and admission control decisions at the AP. In addition, the AP collects statistics about the non-AP STA and reports the statistics to the SSPN when requested. The SSPN may also send service provision instructions to the AP, e.g., to terminate the connection to a non-AP STA. Non-AP STAs do not support the SSPN Interface.

Network deployments typically provide that the AP and the server in the SSPN have a trustworthy channel that can be used to exchange information, without exposure to or influence by any intermediate parties. The establishment of this secure connection between the IEEE 802.11 infrastructure and the SSPN is outside the scope of this standard.

11.25.5.2 Authentication and cipher suites selection with SSPN

When the non-AP STA initiates IEEE 802.1X authentication, the EAP messages are forwarded to the SSPN based on the home realm information provided by the non-AP STA. If the IEEE 802.11 infrastructure is unable to forward the EAP message, the AP when dot11SSPNInterfaceActivated is true shall disassociate the non-AP STA with Reason Code NO_SS_P_ROAMING AGREEMENT.

In addition to the EAP messages, the IEEE 802.11 infrastructure also provides extra information regarding the non-AP STA to the SSPN as defined in R.4.2, e.g., the Cipher Suite supported by non-AP STA, the location of the AP to which the non-AP STA is associated, etc. Such information may be used by the SSPN to make authentication and service provisioning decisions.

In the SSPN Interface Service, the SSPN uses more information than is carried over EAP to decide on the authentication result. The SSPN might reject a connection request if the cipher suites supported by non-AP STA does not meet its security requirements. In this situation, the SME of the AP when `dot11SSPNInterfaceActivated` is true shall invoke a disassociation procedure as defined in 11.3.5.8 by issuing the `MLME-DISASSOCIATE.request` primitive. The AP disassociates the corresponding non-AP STA with Reason Code `BAD_CIPHER_OR_AKM`.

The SSPN might reject the association request based on the location of the non-AP STA, e.g., if the non-AP STA is requesting association to an AP or associated to an AP located in a forbidden zone. In this situation, the SME of the AP when `dot11SSPNInterfaceActivated` is true shall invoke a disassociation procedure as defined in 11.3.5.8 by issuing the `MLME-DISASSOCIATE.request` primitive. The AP disassociates the corresponding non-AP STA with Reason Code `NOT_AUTHORIZED_THIS_LOCATION`.

11.25.5.3 Reporting and session control with SSPN

An AP with `dot11SSPNInterfaceActivated` equal to true shall create a `dot11InterworkingEntry` in its `dot11InterworkingTable` for each STA that successfully associates. Permissions received from the SSPN for each associated STA shall be populated into the table; if no permissions are received from the SSPN for a particular non-AP STA, then the default permissions or an AP's locally defined policy may be used for that STA's `dot11InterworkingEntry`. If the AP's local policy is more restrictive than an object's permission value received from the SSPN Interface, then the AP's local policy may be enforced instead.

In an AP when `dot11SSPNInterfaceActivated` is equal to true, the following procedure occurs:

- The non-AP STA's state contained in the `dot11InterworkingEntry` shall be transmitted to the new AP after a successful transition. The state definition and the protocol used to transfer the state are beyond the scope of this standard. The new AP shall not forward any frames for that non-AP STA until it receives the `dot11InterworkingEntry` from the prior AP.
- After the state is successfully transmitted to the new AP, the `dot11InterworkingEntry` for that non-AP STA shall be deleted from the prior AP's `dot11InterworkingTable`.

An AP with `dot11SSPNInterfaceActivated` equal to true shall delete the `dot11InterworkingEntry` for a non-AP STA when it disassociates from the BSS.

An AP with `dot11SSPNInterfaceActivated` equal to true shall enforce the `dot11InterworkingEntry` limits for a particular non-AP STA by comparing the values of octet counters to authorized access limits:

- `dot11NonAPStationVoiceOctetCount` is compared to `dot11NonAPStationAuthMaxVoiceOctets`. When the value of the authorized maximum octet count is exceeded, if the ACM field for AC_VO is equal to 1 then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set 6 or 7, or if the ACM field for AC_VO is equal to 0 then the non-AP STA shall be disassociated using the `MLME-DISASSOCIATE.request` primitive with a reason code of `PEER_INITIATED`.
- `dot11NonAPStationVideoOctetCount` is compared to `dot11NonAPStationAuthMaxVideoOctets`. When the value of the authorized maximum octet count is exceeded, if the ACM field for AC_VI is equal to 1 then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set 4 or 5, or if the ACM field for AC_VI is equal to 0 then the non-AP STA shall be disassociated using the `MLME-DISASSOCIATE.request` primitive with a reason code of `PEER_INITIATED`.

- dot11NonAPStationBestEffortOctetCount is compared to dot11NonAPStationAuthMaxBestEffort-Octets. When the value of the authorized maximum octet count is exceeded, if the ACM field for AC_BE is equal 1 then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set 0 or 3, or if the ACM field for AC_BE is equal 0 then the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.
- dot11NonAPStationBackgroundOctetCount is compared to dot11NonAPStationAuthMaxBackgroundOctets. When the value of the authorized maximum octet count is exceeded, if the ACM field for AC_BK is equal 1 then the HC shall delete all admitted TSs on this access category and deny all subsequent ADDTS Request frames with TID set 1 or 2, or if the ACM field for AC_BK is equal 0 then the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.
- dot11NonAPStationHCCAHEMMOctetCount is compared to dot11NonAPStationAuthMaxHCCAHEMMOctets. When the value of the authorized maximum octet count is exceeded, then the HC shall delete all admitted TSs with access policy of HCCA or HEMM and deny all subsequent ADDTS Request frames with access policy equal HCCA or HEMM.
- The sum of dot11NonAPStationVoiceOctetCount, dot11NonAPStationVideoOctetCount, dot11NonAPStationBestEffortOctetCount, dot11NonAPStationAuthMaxBackgroundOctets, and dot11NonAPStationHCCAHEMMOctetCount is compared to dot11NonAPStationAuthMaxTotal-Octets. When the value of the authorized maximum octet count is exceeded, the non-AP STA shall be disassociated using the MLME-DISASSOCIATE.request primitive with a reason code of PEER_INITIATED.

11.25.6 Interworking procedures: emergency services support

Emergency services support provides STAs with the ability to contact authorities in an emergency situation. The following procedures allow the STA to determine whether emergency services are supported by the AP or mesh STA, and whether unauthenticated emergency service access is allowed.

In an AP, when dot11ESNetwork is true, the network is dedicated and limited to accessing emergency services. When dot11ESNetwork is true, the Access Network Type field in the Interworking element shall be set to the value for “Emergency services only network” (see Table 9-214). When dot11ESNetwork is false, the network is not limited to accessing emergency services, and the Access Network Type field in the Interworking element shall be set to a value other than “Emergency services only network.” See Table 11-16.

Table 11-16—ESR and UESA field settings

| Description | ESR | UESA |
|---|-----|------|
| It is unspecified whether emergency services are reachable. | 0 | 0 |
| Emergency services are only reachable for authenticated STAs. | 1 | 0 |
| Reserved | 0 | 1 |
| Emergency services are reachable for STAs. | 1 | 1 |

When an AP is located in a regulatory domain that requires emergency location capabilities, the ESR field shall be set to 1; otherwise the ESR field shall be set to 0. When an AP is located in a regulatory domain that requires emergency location capabilities and location capability is enabled on the AP, the Network Type shall be set to “Emergency services only network” (see Table 9-214), if location capability is enabled on the AP;

otherwise the ESR field shall not be set to 1 and the Network Type shall not be set to “Emergency services only network”. In Beacon and Probe Response frames, location capability is advertised when the Civic Location or Geo Location field in the Extended Capabilities Element is set to 1.

In an MBSS, if location capability is supported, the mesh STA shall report its location for emergency services.

When dot11ESNetwork is true in a mesh STA, the ESR shall be set to 1. When that mesh STA receives a Mesh Peering Open frame that includes the Interworking element with the ASRA field equal to 1, it allows access to emergency services and forwards MSDUs to an emergency server.

NOTE—The ASRA bit set to 1, informs the mesh STA to prioritize resources for the emergency call, to proactively find a better path before the link conditions deteriorate below a certain threshold, and/or to change some of the mesh STA’s behavior (for example, to disable any power save features).

When dot11ESNetwork is false in a mesh STA, the ESR shall be set to 0. When that mesh STA receives a Mesh Peering Open frame that includes the Interworking element with the ASRA field equal to 1, it is unable to support the mesh peering of emergency services and does not forward MDSUs to an emergency server.

11.25.7 Interworking procedures: emergency alert system (EAS) support

The EAS provides alerts, typically issued by authorities. The Interworking Procedures EAS support enables the alerts to be transmitted upon request from APs to non-AP STAs. Subsequent to advertisement in Beacon and Probe Response frames, a non-AP STA uses GAS queries to retrieve an EAS message from the network according to the following procedures.

When dot11EASActivated is true, EAS operation shall be supported. When EAS operation is not supported, dot11EASActivated shall be equal to false.

When the IEEE 802.11 infrastructure is informed of the availability of an EAS message (the mechanism by which is outside the scope of this standard), an AP with dot11EASActivated equal true shall advertise the availability of the EAS message by including an Emergency Alert Identifier element (see 9.4.2.97) for that message in its Beacon and Probe Response frames. The AP shall include one instance of an Emergency Alert Identifier element in its Beacon and Probe Response frames for each active EAS Message. The Emergency Alert Identifier element provides an Alert Identifier Hash value, a unique indicator of the EAS Message of the alert to the non-AP STA. The Alert Identifier Hash value allows the non-AP STA to determine whether this is a new alert.

NOTE—The same value of hash will be computed by each AP in an ESS and by each AP in different ESSs. Thus a non-AP STA, which can download emergency alert messages when in a preassociated state, can unambiguously determine that it has already downloaded the message, avoiding unnecessary duplicates.

When an EAS Message has expired (the mechanism by which is outside the scope of this standard), an AP with dot11EASActivated equal true shall remove the corresponding instance of an Emergency Alert Identifier element from its Beacon and Probe Response frames.

The Alert Identifier Hash in the Emergency Alert Identifier element shall be computed using HMAC-SHA-1-64 hash algorithm as shown in 9.4.2.97.

After receiving an Alert Identifier Hash value for an EAS Message that has not already been retrieved from the network, a non-AP STA having dot11EASActivated equal true can retrieve the EAS message from the AP as follows

- The procedures defined in 11.25.3.2, transmit the Alert Identifier Hash of the desired message in the Query request field of a GAS Initial Request frame. The Advertisement Protocol ID field in the GAS Initial Request frame is set to the value for EAS (see Table 9-215).
- The Query response is a message formatted in accordance with OASIS EDXL.

- A URI is formed by concatenating the Emergency Alert URI with the hexadecimal numerals of the Alert Identifier Hash converted to lowercase ASCII encoded characters and the “.xml” file extension. For example, if the Emergency Alert URI is <http://eas.server.org> and the Alert Identifier Hash is 0x1234567890abcdef, then the URI would be <http://eas.server.org/1234567890abcdef.xml> (the mechanism by which the URI is retrieved is outside the scope of this standard). The XML file is formatted in accordance with OASIS EDXL. The non-AP STA retrieves the Emergency Alert URI (see 9.4.5.16) using an ANQP request according to the procedures in 11.25.3.3. This method is recommended for non-AP STAs in the associated state.

11.25.8 Interworking procedures: support for the advertisement of roaming consortiums

APs can assist non-AP STAs performing network discovery and selection through the advertisement of a Roaming Consortium element. The Roaming Consortium element contains information identifying an SSP or group of SSPs (i.e., a roaming consortium) whose security credentials might be used to authenticate with the AP transmitting this element. An SSP or group of SSPs can register for and obtain an OI using the procedures described in [B19]. Note that a non-AP STA may also use GAS procedures defined in 11.25.3.3.3 to retrieve a Roaming Consortium ANQP-element, which might contain more OIs than the Roaming Consortium element.

APs having `dot11InterworkingServiceActivated` equal true and having one or more entries in the `dot11RoamingConsortiumTable` shall include the Roaming Consortium element in Beacon and Probe Response frames. An AP shall only include an OI in the `dot11RoamingConsortiumTable`, if, in conjunction with an AS, the AP is capable of successfully authenticating a non-AP STA that holds valid security credentials for the SSPN identified by that OI. Methods used by the AP to authenticate the non-AP STA include, but are not limited to, RSNA algorithms and Open System authentication.

A non-AP STA might have a locally stored binding between an OI and a set of security credentials with which it can authenticate to the network identified by the OI, that is, the SSPN. The method by which this binding is obtained is outside the scope of this standard. A non-AP STA might select from that list of credentials when authenticating to the BSS.

11.25.9 Interworking procedures: support for QoS mapping from external networks

Maintaining proper end-to-end QoS is an important factor when providing interworking service. This is because the external networks might employ different network-layer (Layer 3) QoS practices. For example, the use of a particular differentiated services code point (DSCP) for a given service might be different between different networks. To provide proper QoS over-the-air in the IEEE 802.11 infrastructure, the mapping from DSCP to UP for the corresponding network needs to be identified and made known to the STAs. If an inconsistent mapping is used then:

- Admission control at the AP may incorrectly reject a service request, because the non-AP STA used the incorrect UP.
- Non-AP STAs might use the incorrect value for User Priority in TSPEC and TCLAS elements.
- The user might be given a different QoS over the IEEE 802.11 network than expected, e.g., a lower QoS might be provided than the STA expected.

Therefore, APs with `dot11QosMapActivated` equal true shall set the QoS Map field in the Extended Capabilities element to 1; APs with `dot11QosMapActivated` equal false shall set the QoS Map field in the Extended Capabilities element to 0. The AP’s SME causes the QoS mapping to be available to higher layer protocols or applications so they will be able to set the correct priority in an MA-UNITDATA.request primitive.

For frames transmitted by an AP belonging to an admitted TS, the UP obtained from the TS's TCLAS element shall be used instead of the UP derived from the QoS mapping. For frames transmitted by an AP belonging to an admitted TS not having a TCLAS element, the UP shall be derived from the QoS mapping.

Non-AP STAs when dot11QosMapActivated is equal true shall set the QoS Map field in the Extended Capabilities element to 1. An AP receiving an Association Request frame or Reassociation Request frame when the QoS Map field in the Extended Capabilities element is equal 1 shall include the QoS Map element in the corresponding Association Response frame or Reassociation Response frame as defined in 9.3.3.7 or 9.3.3.9 respectively. Upon receiving the QoS Map element, the non-AP STA's SME causes the QoS mapping to be available to higher layer protocols or applications so they will be able to set the correct priority in an MA-UNITDATA.request primitive.

When the AP's SME detects a change in the QoS mapping information, it shall update the non-AP STA with the new QoS Map element. It accomplishes this update by invoking the MLME-QOS-MAP.request primitive.

When the MAC entity at the non-AP STA receives a QoS Map Configure frame from the AP, the MLME shall issue an MLME-QOS-MAP.indication primitive to its SME.

When the non-AP STA's SME receives the QoS Map response, it shall make the QoS Map available to higher layers so that in turn, they can invoke the MA-UNITDATA.request primitive with the correct priority.

11.26 Quality-of-service management frame (QMF)

11.26.1 General

11.26.1.1 Overview

A QMF STA shall set dot11QMFAutowired and dot11QosOptionImplemented to true. The QMF STA shall assign an access category to each Management frame according to the access category assignments indicated in the QMF policy that has been configured using the configuration procedures described in 11.26.2.

A QMF STA shall set the QMFAutowired subfield in the Extended Capabilities element to 1.

A Management frame shall be transmitted as an IQMF when all five of the following conditions are met:

- The RA of the Management frame corresponds to an individual MAC address.
- The frame is transmitted by a QMF STA.
- The transmitting STA has previously received an Extended Capabilities element from the STA corresponding to the RA of the frame being transmitted.
- The most recently received such Extended Capabilities element indicated that the STA is a QoS STA and has the value of 1 in the QMFAutowired subfield.
- The frame is not a time priority Management frame.

A QMF AP shall transmit a Management frame as a GQMF when all three of the following conditions are met:

- The RA of the Management frame corresponds to a group MAC address.
- The transmitting STA has received an Extended Capabilities element that has the QMFAutowired subfield equal to 1 from every member of the BSS corresponding to the BSSID of the Management frame.
- The frame is not a time priority Management frame.

A non-AP QMF STA shall transmit a Management frame as a GQMF when all three of the following conditions are met:

- The RA of the Management frame corresponds to a group MAC address.
- The transmitting STA has received an Extended Capabilities element that has the QMFActivated subfield equal to 1 from its associated AP.
- The frame is not a time priority Management frame.

A Management frame shall not be transmitted as an IQMF or GQMF, except as defined above.

NOTE—This standard assumes that all APs in an ESS are configured consistently for QMF service when GQMF has been enabled for use by associated non-AP STAs.

When the QMFActivated subfield is zero in the most recently received Extended Capabilities element from a destination STA, or when an Extended Capabilities element has not been received from a destination STA, a transmitting QMF STA shall transmit individually addressed Management frames to that destination STA using access category AC_VO.

If the QMFActivated subfield in the most recently received Extended Capabilities element from a destination QMF STA is equal to 1, but no QMF Policy element has been received from the destination QMF STA, and, if associated, no QMF Policy element has been received from the QMF AP with which the STA is associated, then a QMF STA shall transmit all IQMFs to the destination QMF STA using the default QMF policy access categories defined in Table 11-17. Otherwise, the QMF STA shall transmit individually addressed Management frames as defined in the QMF policy included in the QMF Policy element accepted from the destination QMF STA. In either case, the transmitted Management frames are IQMFs, and the transmitting QMF STA shall indicate the access category used to transmit the frame in the ACI subfield of the sequence number field.

A QMF STA in an unassociated state shall transmit all group-addresses Management frames as non-QMF. An associated QMF STA shall follow the QMF policy dictated by its associated AP for transmitting GQMFs as described in 11.26.2. The specific access category assignments of different Management frames in a nondefault QMF policy are beyond the scope of this document. The transmitting QMF STA shall indicate the access category used to transmit GQMFs in the ACI subfield of the sequence number field.

Time-priority Management frames, when not sent as an immediate response, shall be transmitted using AC_VO.

11.26.1.2 Default QMF policy

The default QMF policy is as defined in Table 11-17. It defines the access category of each Management frame based on management subtype value, category value, and action value. QMFs not included in this table shall be assigned an access category AC_BE.

Table 11-17—Default QMF policy

| Description | Management Frame Subtype value from Table 9-1 | Category value from Table 9-47 | Action field | QMF access category |
|--|---|--------------------------------|--------------|---------------------|
| (Re)Association Request/Response | 0000–0011 | N/A | N/A | AC_VO |
| Probe Request (individually addressed) | 0100 | N/A | N/A | AC_VO |

Table 11-17—Default QMF policy (continued)

| Description | Management Frame Subtype value from Table 9-1 | Category value from Table 9-47 | Action field | QMF access category |
|--|---|--------------------------------|----------------------|---------------------|
| Probe Request (group addressed) | 0100 | N/A | N/A | AC_BE |
| Probe Response | 0101 | N/A | N/A | AC_BE |
| Timing Advertisement | 0110 | N/A | N/A | AC_BE |
| Beacon, ATIM, Disassociation, Authentication, Deauthentication | 1000–1100 | N/A | N/A | AC_VO |
| Spectrum management | 1101 | 0 | 0–3 | AC_BE |
| Spectrum management—channel switch announcement | 1101 | 0 | 4 | AC_VO |
| QoS | 1101 | 1 | 0–3 | AC_VO |
| DLS | 1101 | 2 | 0–2 | AC_BE |
| Block Ack | 1101 | 3 | 0–2 | AC_VO |
| Public | 1101 | 4 | 0, 1, 3, 5–6, 8–9 | AC_BE |
| Public—DSE deenablement, extended channel switch announcement | 1101 | 4 | 2, 4 | AC_VO |
| Public—measurement pilot | 1101 | 4 | 7 | AC_VO |
| Public—TDLS Discovery Response | 1101 | 4 | 14 | AC_VO |
| Public—Fine Timing Measurement Request | 1101 | 4 | 32 | AC_VO |
| Public—Fine Timing Measurement | 1101 | 4 | 33 | AC_VO |
| Radio measurement | 1101 | 5 | 0–5 | AC_BE |
| Fast BSS Transition | 1101 | 6 | 0–4 | AC_VO |
| HT | 1101 | 7 | 0–3 | AC_VO |
| HT | 1101, 1110 | 7 | 4–7 | AC_VO |
| SA Query | 1101 | 8 | 0–1 | AC_VO |
| Protected Dual of Public Action | 1101 | 9 | 1–2, 5–6, 8–9 | AC_BE |
| Protected Dual of Public Action—extended channel switch announcement | 1101 | 9 | 4 | AC_VO |
| WNM | 1101 | 10 | 0–24 | AC_BE |

Table 11-17—Default QMF policy (*continued*)

| Description | Management Frame Subtype value from Table 9-1 | Category value from Table 9-47 | Action field | QMF access category |
|---|---|--------------------------------|--------------|---------------------|
| Unprotected WNM | 1101 | 11 | 0–1 | AC_BE |
| Mesh Action—HWMP Mesh Path Selection | 1101 | 13 | 1 | AC_VO |
| Mesh Action—Congestion Control | 1011 | 13 | 3 | AC_VO |
| Mesh Action | 1101 | 13 | 0, 2, 4–10 | AC_BE |
| Multihop Action | 1101 | 14 | 0–1 | AC_BE |
| Self Protected | 1101 | 15 | 0–5 | AC_VI |
| DMG | 1101 | 16 | 0–22 | AC_BE |
| Reserved (used by (used by the Wi-Fi Alliance ^a)) | 1101 | 17 | All | AC_BE |
| Fast Session Transfer | 1101 | 18 | 0–5 | AC_VO |
| Robust AV Streaming | 1101 | 19 | 0–3 | AC_BE |
| Unprotected DMG | 1101 | 20 | 0–1 | AC_VO |
| VHT | 1101, 1110 | 21 | 0–2 | AC_VO |
| Vendor-specific Protected | 1101 | 126 | N/A | AC_BE |
| Vendor-specific | 1101 | 127 | N/A | AC_BE |

^aSee <http://www.wi-fi.org>.

11.26.2 QMF policy advertisement and configuration procedures

11.26.2.1 Overview

QMF policies are exchanged and implemented between two QMF STAs. A STA's QMF policy is advertised and exchanged using the QMF Policy element described in 9.4.2.120.

A non-AP QMF STA operating in a BSS shall not transmit a QMF Policy frame to an AP.

The access category for a QMF that is transmitted by a non-AP QMF STA to a peer QMF STA shall be determined from the QMF policy received from the peer if a QMF policy has been received from the peer. Otherwise, the default policy shall be used. The access category for a QMF that is transmitted by a QMF AP is determined from the QMF policy configured at that AP.

In a BSS or MBSS, the access category for any Management frame may be reconfigured. For example, vendor-specific and vendor-specific protected Management frames might be reconfigured to suit the vendor application requirements.

11.26.2.2 QMF policy change in an infrastructure BSS or in an MBSS

A QMF Policy Change frame is transmitted by a QMF STA to request a change to the QMF policy that the requesting QMF STA will use for transmitting Management frames to the peer QMF STA in an infrastructure BSS or in an MBSS.

A STA may transmit a QMF Policy Change frame to request a change in the QMF policy for transmitting to a peer STA. A non-AP QMF STA that receives a QMF Policy Change frame may either accept or reject the request. An associated non-AP QMF STA may transmit a QMF Policy Change to the QMF AP in its BSS only if the Extended Capabilities element received from the AP has its QMFReconfigurationActivated subfield equal to 1. If the AP rejects the request, the associated QMF STA shall not request the same policy reconfiguration from the AP during the lifetime of its association.

An AP shall respond to a QMF Policy Change frame received from an associated STA by transmitting a QMF Policy frame. If the QMFReconfigurationActivated subfield is zero in the Extended Capabilities element in the Beacon frame, an AP that receives a QMF Policy Change frame from an associated STA shall respond with a QMF Policy frame, with Status Code set to REQUEST_DECLINED. If the QMFReconfigurationActivated subfield is 1 in the Extended Capabilities element in the Beacon frame, an AP that receives a QMF Policy Change frame from an associated STA shall evaluate the QMF Policy included in the frame, and shall respond to the request with the resulting QMF Policy element and Status Code set to SUCCESS if it accepts the policy change, or REQUEST_DECLINED if it rejects the policy change. A QMF AP may transmit a QMF Policy frame with Status Code set to SUCCESS to an associated QMF STA without having first received a QMF Policy Change frame from that STA.

If an accept status is received in a QMF Policy frame within dot11QMFPolicyChangeTimeout of having transmitted a QMF Policy Change frame with the same dialog token to the STA that transmitted the QMF Policy frame, then the requesting QMF STA shall transmit any subsequently queued Management frames to the peer QMF STA in accordance with the changes to the QMF policy that were indicated in the QMF Policy Change frame.

If a reject status is received in a QMF Policy frame within dot11QMFPolicyChangeTimeout of having transmitted a QMF Policy Change frame with the same dialog token to the STA that transmitted the QMF Policy frame as a response to a QMF Policy Change frame, then the configuration change request is rejected and the requesting QMF STA shall continue to transmit Management frames to the peer QMF STA in accordance with the previously configured QMF policy. The requesting QMF STA shall not transmit a QMF Policy Change frame with a previously rejected QMF policy to a peer QMF STA within dot11QMFPolicyChangeTimeout from the time the requesting STA received the rejection frame.

If the requesting STA does not receive a QMF Policy frame in response to a QMF Policy Change frame within dot11QMFPolicyChangeTimeout, then the requesting STA shall continue to transmit frames according to the previously configured QMF policy.

If a QMF STA has received an Extended Capabilities element with the QMFReconfigurationActivated subfield equal to 0 or has not received an Extended Capabilities element from a destination QMF STA, the QMF STA shall not transmit a QMF Policy Change frame to the destination QMF STA.

A QMF mesh STA or a QMF AP may set dot11QMFRConfigurationActivated to true or false. A non-AP QMF STA in an infrastructure BSS shall set dot11QMFRConfigurationActivated to true and shall set the QMFReconfigurationActivated subfield to 1 in transmitted (re)association requests. A non-AP QMF STA with dot11QMFRConfigurationActivated equal to true shall accept any received QMF Policy frame from its associated AP. A QMF STA with dot11QMFRConfigurationActivated equal to false shall respond with a QMF Policy frame, with the current QMF Policy element and Status Code set to REQUEST_DECLINED.

The QMFReconfigurationActivated subfield shall be set to one in the Extended Capabilities element when dot11QMFReconfigurationActivated is true. The QMFReconfigurationActivated subfield shall be set to 0 in the Extended Capabilities element when dot11QMFReconfigurationActivated is false.

The SME of a peer QMF STA uses the MLME-QMFPOLICY primitives (see 6.3.85.2 to 6.3.85.3) to transmit a QMF Policy frame to a peer STA. The SME of a peer STA uses the MLME-QMFPOLICY.request primitive to transmit a QMF Policy frame to a peer STA. The MLME of a peer QMF STA shall set the dialog token to 0 and set the Status Code to SUCCESS when the QMF Policy frame is transmitted unsolicited to the peer STA.

The SME of a peer QMF STA uses the MLME-QMFPOLICYCHANGE primitives (see 6.3.85.4 to 6.3.85.7) to exchange the QMF Policy Change and QMF Policy frames. The SME of a peer STA uses the MLME-QMFPOLICYCHANGE.request primitive to transmit a QMF Policy Change frame to a peer STA. The value of the dialog token in the MLME-QMFPOLICYCHANGE.request primitive shall be set to a value in the range 1 to 255.

The SME of the peer STA evaluates the QMF policy and uses the MLME-QMFPOLICYCHANGE.response primitive to transmit a QMF Policy frame to the STA including the result of the QMF policy change. The value of the dialog token in the MLME-QMFPOLICYCHANGE.response primitive shall be set to the value of the dialog token received in the corresponding MLME-QMFPOLICYCHANGE.indication primitive.

When the QMF STA SME receives an MLME-QMFPOLICYCHANGE.confirm primitive or MLME-QMFPOLICY.indication primitive with Result Code of SUCCESS, it shall set the new QMF policy using the MLME-QMFPOLICYSET.request primitive.

An AP for which dot11AlternateEDCAActivated is true shall not use the alternate video (A_VI) nor alternate voice (A_VO) transmit queues in its QMF policy.

11.26.2.3 QMF policy configuration in an infrastructure BSS

A QMF AP shall include the QMF Policy element in Beacon frames that it transmits. Non-AP QMF STAs acquire QMF policy configuration information from QMF Policy elements received in Beacon, Association Response, Reassociation Response, Probe Response, and QMF Policy frames. The interpretation of the QMF Policy element is described in 11.26.3.

An associated QMF STA transmitting QMFs shall transmit those frames in accordance with the QMF policy received from its associated AP in the following order of precedence, from highest to lowest:

- QMF policy defined in an unsolicited QMF Policy frame from the associated QMF AP or the QMF Policy Change frame that resulted in a successful response QMF Policy frame from the associated AP, whichever occurred most recently
- QMF policy defined in the QMF Policy element received in the successful (Re)Association Response frame

All unassociated QMF STAs transmitting Management frames to a QMF AP shall transmit those frames to the AP in accordance with the QMF policy in the most recently received Beacon or Probe Response frame from that AP. If no frame containing a QMF Policy element has been received from the AP prior to the transmission of the Management frame(s), then the Management frame(s) shall be transmitted using the access categories of the default QMF policy defined in Table 11-17.

A QMF STA shall transmit all Management frames that are individually addressed to non-QMF STAs using access category AC_VO.

A QMF AP shall set a QMF policy for the transmission of QMFs to its associated STAs. The QMF policy used by the AP for transmission of QMFs to associated STAs is not required to be the same as the QMF policy it advertises.

If the QMFRerconfigurationActivated subfield is equal to 1 in the Extended Capabilities element of the Beacon or Probe Response frame transmitted by the AP, an associated QMF STA may use the QMF Policy Change frame to request a change in its existing QMF policy.

11.26.2.4 QMF policy configuration in an IBSS or OCB

QMF STAs in an IBSS or OCB shall use the default QMF policy for all individually addressed Management frames transmitted to other QMF STAs in the IBSS or OCB.

11.26.2.5 QMF policy configuration in an MBSS

A QMF STA operating in an MBSS shall set the QMFActivated subfield in the Extended Capabilities element to true. The Mesh Beacon frame shall not include a QMF Policy element. The QMF in an MBSS policy shall be set on a per link basis between two QMF STAs.

The QMF Policy Change and QMF Policy frames are used by QMF STAs in an MBSS to configure QMF policy. See 11.26.2.2.

A QMF STA shall always accept the QMF policy from the QMF Policy frame transmitted by the peer QMF STA and shall transmit all individually addressed Management frames destined to the peer QMF STA using the received QMF policy.

A QMF STA may request a change in the QMF policy from a peer QMF STA by transmitting a QMF Policy Change to the peer QMF STA. The peer QMF STA may accept or reject this change request. If the peer QMF STA accepts the change, it shall respond with a QMF Policy frame with Status Code set to SUCCESS and the QMF STA shall transmit IQMFs using the new QMF policy to the peer QMF STA. If the peer QMF STA rejects the change, it shall respond with QMF Policy frame with Status Code set to REQUEST_DECLINED and the QMF STA shall continue transmitting IQMFs according to the previously configured QMF policy.

If a QMF STA does not receive a QMF Policy frame from a peer QMF STA, it shall transmit Management frames to that peer STA using the default QMF policy.

QMF STAs in an MBSS shall not include policies for group addressed Management frames in the QMF Policy Config Request.

11.26.3 Interpreting QMF access categories

The QMF Policy element, as defined in 9.4.2.120, indicates the transmit access categories of different Management frames. A QMF Policy element with Length field of value 1 means that the access category of all Management frames is as defined in the default QMF policy in Table 11-17.

When the value of the Individually Addressed subfield is 1, then the QACM applies to IQMFs. When the value of the Group Addressed subfield is 1, then the QACM applies to GQMFs. A STA shall not transmit a QMF Policy element with both the Individually Addressed and Group Addressed subfields set to 0 in any of the included QACM subfields.

The QMF Policy element contains zero or more QACM fields. When included in the QMF Policy element, each QACM field indicates the access category of a group of Management frames. Using the description from Table 11-18, access categories for all Management frames belonging to either a given subtype or a

given action category may be indicated in a single QACM field. When multiple Action frames of the same Category are to be mapped to the same Access Category, this is indicated by setting multiple bits in the Action Value Bitmap. For example, setting Bit 0 and Bit 1 indicates Event Request/Response frames when the Management Frame Subtype subfield refers to Management frames of subtype Action and the Category Value subfield refers to the WNM category. The QACM field also may be used to indicate the access category of a single management frame subtype.

A QMF STA that received a QMF Policy element from its associated QMF AP shall discard any previously received QMF Policy elements. If a Management frame is indicated in multiple QACM fields, the access category of the Management frame is determined by the access category defined in the last QACM field in the QMF Policy that contains the access category assignment of the corresponding Management frame. For example, if an QACM field sets the entire WNM category to access category AC_BE and a later QACM field sets Event Request/Report of WNM category to AC_BK, then all Action frames of WNM category are transmitted using access category AC_BE with the exception of Event Requests/Reports, which are transmitted using access category AC_BK.

Table 11-18—QMF policy description for valid combination of optional fields in the QACM field

| QACM field Length subfield | Action frame category | Action Value Bitmap subfield | Description |
|-----------------------------------|------------------------------|-------------------------------------|---|
| 0 | Not included | Not included | Policy to be applied to all Management frames of the corresponding subtype |
| 1 | Included | Not included | Policy to be applied to all Action frames of corresponding category value |
| ≥ 2 | Included | Included | Policy to be applied only to Action frames indicated via the action value bitmap for Management frames of the subtype indicated in the Management Frame Subtype subfield and the category value indicated in the Action Frame Category subfield in the corresponding QACM field |

11.27 Robust AV streaming

11.27.1 Robust AV streaming dependencies

When dot11RobustAVStreamingImplemented is true, the STA is a robust AV streaming STA. The attribute dot11QoSOptionImplemented shall be true in a robust AV streaming STA.

11.27.2 SCS procedures

The stream classification service (SCS) is a service that may be provided by an AP to its associated STAs that support SCS. In SCS, the AP classifies incoming unicast MSDUs based upon parameters provided by the non-AP STA.

The classification allows the UP, drop eligibility, and EDCA transmit queue to be selected for all MSDUs matching the classification.

Implementation of SCS is optional for a STA. A STA that implements SCS shall set its dot11SCSImplemented to true. A STA whose dot11SCSActivated value is true shall support stream classification and shall set to 1 the SCS field of the Extended Capabilities elements that it transmits. If dot11SCSActivated is true, dot11SCSImplemented shall be true.

A non-AP STA that supports SCS may request use of SCS by sending an SCS Request frame that includes an SCS Descriptor element with the Request Type field set to “Add” or “Change.” The SCS Descriptor List field in the SCS Descriptor element identifies how MSDUs are classified and the priority to assign to MSDUs that match this classification. If the TCLAS Processing element is present in an SCS Descriptor element, the Processing subfield shall have a value of 0 or 1. An AP shall decline any SCS Request frame where a TCLAS Processing element is present and the Processing subfield does not have a value of 0 or 1.

Each SCS stream is identified by an SCSID. This SCSID is used by a non-AP STA to request creation, modification, or deletion of an SCS stream. The SCSID is used by an AP to identify an SCS stream in SCS responses.

Upon receipt of an SCS Request frame from an associated non-AP STA, the AP shall respond with a corresponding SCS Response frame. A value of “SUCCESS” shall be set in the corresponding Status field of the SCS Status tuple in the SCS Response frame when the AP accepts the SCS request for the requested SCSID. A value of “REQUEST_DECLINED,” “REQUESTED_TCLAS_NOT_SUPPORTED_BY_AP,” or “INSUFFICIENT_TCLAS_PROCESSING_RESOURCES” shall be set in the corresponding SCS Status field of the SCS Status tuple in the SCS Response frame when the AP denies the SCS request for the requested SCSID.

If the AP declines a request to change a previously accepted SCSID, the previously accepted classification for this SCSID continues to operate.

If the requested SCS is accepted by the AP, the AP shall process subsequent incoming unicast MSDUs from the DS or WM that match the TCLAS elements and optional TCLAS Processing element classifier specified in the SCS Descriptor element.

A match of the classifier is defined as follows:

- When the Processing subfield of the TCLAS Processing element is 0, the classifier matches all of the parameters in the TCLAS elements in the SCS Descriptor element.
- When the Processing subfield of the TCLAS Processing element is 1 or the TCLAS Processing element is not present, the classifier matches if the parameters match at least one of the TCLAS elements in the SCS Descriptor element.

The processing of matching MSDUs depends upon the access policy assigned to the MSDU:

- For matching MSDUs that are not part of a TS (as described in 11.4), the User Priority subfield of the Intra-Access Category Priority element is used as the UP of these MSDUs.
- For matching MSDUs that are part of a TS (as described in 11.4), the TID and UP classification of these MSDUs shall follow the rules specified in 11.4.8.
- If dot11AlternateEDCAActivated is true, for matching MSDUs that are not part of a TS (as described in 11.4) or for MSDUs that are part of a TS that uses EDCA or HEMM as the access policy, the Alternate Queue subfield of the Intra-Access Category Priority element is used to select whether the primary EDCA transmit queue or alternate EDCA transmit queue is used for these MSDUs.
- All matching MSDUs have their DEI set using the value from the Drop Eligibility subfield of the Intra-Access Category Priority element in the DEI subfield of the HT Control field, as defined in 9.2.4.6.

A non-AP STA may request the termination of an accepted SCS stream by sending an SCS Request frame with the Request Type field set to “Remove” and the requested SCSIDs in the SCS Descriptor element. The Length field of the SCS Descriptor element is set to 0; and no Intra-Access Priority, TCLAS, or TCLAS Processing elements shall be included in the SCS Descriptor element.

Upon reception of a request to terminate a previously accepted SCS stream, the AP shall cease to apply the classifier related to this SCSID. The AP shall send an SCS Response frame to confirm the termination of the SCS stream identified by the SCSID, by including the SCSID and a value of “Terminate” in the Status field of an SCS Status duple in an SCS Response frame and the dialog token in the SCS Response frame set to the value from the SCS Request frame that requested termination.

The AP may send an unsolicited SCS Response frame at any time to cancel a granted SCS stream identified by the SCSID, by including the SCSID and a value of “Terminate” in the Status field of an SCS Status duple in an SCS Response frame and the dialog token in the SCS Response frame set to 0.

11.28 Procedures to manage OBSS

11.28.1 General

QLoad Report elements, HCCA TXOP Update Count elements, HCCA TXOP Advertisement action frames, and HCCA TXOP Response frames are designed to mitigate the effects of OBSSs and provide the means to

- Advertise QoS load information for channel selection
- Extend the admission control and scheduled mechanisms to a distributed environment
- Enable the coordination of scheduled HCCA TXOPs between HCs operating with OBSSs

OBSS APs are APs that are using the same primary channel and that are able to receive or obtain frames from each other, including Beacon frames. These frames are received directly or via associated STAs that support the Beacon request capability (as indicated by the Beacon Passive Measurement Capability Enabled bit or the Beacon Active Measurement Capability Enabled bit being set in the RM Enabled Capabilities element in the (Re)Association frame). An AP might scan other channels as part of its channel selection process or might request associated STAs that support the Beacon request capability to perform an off-channel Beacon request measurement, and these procedures might provide QLoad Report elements received from APs operating on other channels. Subclause T.3 provides an example of using QLoad Reports from adjacent channels.

NOTE 1—These OBSS procedures might use unauthenticated Beacon frames and Public Action frames. Implementations might choose to use additional heuristics (e.g., a history of collaboration and traffic monitoring) to determine the authenticity of this information.

NOTE 2—These OBSS procedures are intended for stationary and portable APs (see 4.2.4).

11.28.2 QLoad Report element

11.28.2.1 Introduction

The QLoad Report element is contained in QLoad Report frames or Protected QLoad Report frames that are provided by an AP and, optionally, periodically in the Beacon frame. The QLoad Report frame is transmitted, upon the receipt of a QLoad Request frame by an AP for which dot11QLoadReportActivated is true, to the STA that sent the QLoad Request frame. An AP shall not send a QLoad Request frame or Protected QLoad Request frame to another AP that has QLoad Report field set to 0 in its Extended Capability element. The Protected QLoad Report frame is transmitted, upon the receipt of a Protected QLoad Request frame when dot11ProtectedQLoadReportActivated is true, to the STA that sent the Protected QLoad Request frame. An AP for which dot11ProtectedQLoadReportActivated is false shall discard any received Protected QLoad Request or Protected QLoad Report frames.

Whenever there is a change in the contents of the QLoad Report element and there is no pending delay period for an unsolicited QLoad Report frame, an unsolicited QLoad Report frame should be transmitted with the RA field set to the broadcast address, after a randomly selected delay between 1 and dot11QLoadReportDelay seconds. After this delay, the AP shall transmit an unsolicited QLoad Report frame that contains the most recently available QLoad information. When dot11QLoadReportActivated is true, the QLoad Report element shall be included in the Beacon frame every dot11QLoadReportIntervalDTIM DTIMs. When dot11QLoadReportActivated is false, the QLoad Report element shall not be included in Beacon frames.

11.28.2.2 Calculating field values

The value of the Potential Traffic Self field represents the potential QoS traffic of this BSS; therefore, the value in the Mean subfield shall always be greater than or equal to the value of the Mean subfield in the Allocated Traffic Self field.

The AP shall include in the Allocated Traffic Self field all accepted and not deleted TSPECs as they are sent by non-AP STAs. At the deletion of each such TSPEC, the AP shall remove the TSPEC from its Allocated Traffic Self field.

The number of active AC_VI and AC_VO streams shall be provided in the Allocated Traffic Self field. For each admitted admission control TSPEC, the AP calculates a medium time, as described in K.2.2. This medium time, however, does not include the medium access overhead that, in turn, is related to the number of streams. This access overhead is further discussed in T.2.7, and a recommendation is given for its value.

An example of a method of calculating the values for the Mean and Standard Deviation subfields in the Potential Traffic Self field is given in T.2.3.

The Sharing Policy field is used to indicate the currently active policy for sharing the medium with OBSSs. Setting the Sharing Policy field to “Static” indicates that the share of the total available medium time of an AP does not change when the value of the Allocated Traffic Shared field changes. Setting the Sharing Policy field to “Dynamic” indicates that the share of the total available medium time of an AP might change when the value of the Allocated Traffic Shared field changes. If the Sharing Policy field has the value “Vendor Specific,” then the QLoad Report element shall contain a Vendor Specific subelement.

If the value of the Overlap field changes, the share of the total available medium time of an AP might change for both static and dynamic sharing policies.

The value of the Potential Traffic Self field represents the potential QoS traffic of this AP and, therefore, shall always be greater than or equal to the values represented by the Allocated Traffic Self field.

The Allocated Traffic Self field contains the mean and standard deviation values of the total EDCA admission control and HCCA traffic that the AP has allocated at any one time and contains the number of AC_VI and AC_VO EDCA admission control streams. As each stream is added or deleted, the AP shall calculate the new value of the Allocated Traffic Self field. A recommended method for calculating the Allocated Traffic Self field mean and standard deviation values is given in T.2.4.

The Allocated Traffic Shared field is calculated from the Allocated Traffic Self field values for all APs that overlap with the AP performing the calculation, including the Allocated Traffic Self field value of the AP performing the calculation. A recommended method for summing the Allocated Traffic Self field values is given in T.2.4.

The EDCA Access Factor is the total traffic bandwidth requirement for all of the OBSSs expressed as a fraction that may be greater than 1. An implementation might calculate the EDCA Access Factor from the summation of the Potential Traffic Self field values of all of the APs that are overlapping, as follows:

- a) Sum all of the Potential Traffic Self field values for all OBSSs, including self, in order to calculate the peak traffic requirement in multiples of 32 μ s per second. As the Potential Traffic Self field value is expressed in terms of mean and standard deviations, it is possible to sum the Potential Traffic Self field values as a composite stream. A suggested method for this summation is given in T.2.3.
- b) Sum all of the HCCA Peak field values from all OBSSs, including self, in order to calculate the peak HCCA traffic requirement, in multiples of 32 μ s per second.
- c) Subtract the value derived in step b) from the value derived in step a). This value is the EDCA traffic.
- d) Sum the AC_VO and AC_VI streams reported in its own QLoad report and all of the QLoad reports of OBSSs. Based upon the number of EDCA streams, an EDCA Overhead Factor can be estimated to account for the medium access time requirements. EDCA Overhead Factor is further discussed in T.2.3, and a recommendation is given for its value.
- e) Multiply together the EDCA traffic from step c) and the EDCA Overhead Factor to obtain a value that represents the total peak bandwidth requirement for the OBSSs. This value is in multiples of 32 μ s per second.
- f) Convert the total peak bandwidth requirement to a fraction that is rounded down to a multiple of 1/64 (8 bits). This value is the EDCA Access Factor. An example for this conversion is given in T.2.6.

The HCCA Peak field value is the sum of the all of the medium times of active TS that use the HCCA or HEMM access policy over a 1 s period for all of the HCCA TSPECs included in the QLoad field. The TXOP time, scheduled by the HC, multiplied by the reciprocal of its SI, is termed the *HCCA medium time*. The HCCA Peak field value is the summation of the HCCA medium times that the HC has scheduled, in multiples of 32 μ s.

The HCCA Access Factor is the total HCCA TXOP medium time requirement for all of the OBSSs expressed as a fraction that may be greater than 1. An implementation might calculate the HCCA Access Factor from the summation of the HCCA Peak field values of all of the APs that in an OBSS, by summation of all of the HCCA Peak field values for all APs in OBSSs and converting this summation to a fraction that is rounded down to 1/64 (8 bits). An example for this conversion is given in T.2.8.

11.28.2.3 Requesting QLoad Reports using radio measurement requests

If an AP has associated STAs that support passive or active beacon measurement (as indicated by the Beacon Passive Measurement Capability Enabled bit or the Beacon Active Measurement Capability Enabled bit being set in the RM Enabled Capabilities element), it may use the neighbor report capability of these associated STAs to attempt to retrieve QLoad Report elements from APs with which the AP is unable to exchange frames directly.

The AP sends a Radio Measurement Request frame that contains a Measurement Request element to an associated STA that supports neighbor reporting and beacon reporting. This Measurement Request element has the Measurement Type field set to “Beacon request” (as defined in Table 9-82), and the BSSID field of the Measurement Request field of the Beacon request frame (as defined in Figure 9-156) is set to the wildcard BSSID. There shall be a Request subelement in the Measurement Request field of the Beacon request frame that contains the Element ID of the QLoad Report element (as defined in Table 9-77) and may contain other element IDs. The SSID subelement shall not be included in the Request subelement of the Measurement Request field of the Beacon request.

Depending upon the signaled enabled radio measurement capabilities of the associated STA, the AP may use either the passive or active measurement mode. The Channel Number field should be set to the primary

channel number that is currently being used by the AP, but may be set to other values if off-channel beacon measurement is supported by the STA to which the measurement request is to be sent.

If the measurement request is accepted, the requested STA performs the measurement request (as described in 11.11). The subsequent Radio Measurement Report frame contains beacon reports for successful measurements. These beacon reports might contain QLoad Report elements inside a Reported Frame Body subelement, if the reporting STA received QLoad Report elements from the Beacon or Probe Response frames that it received from neighboring APs. The contents of these QLoad Report elements can then be used in calculating Allocated Traffic Shared, EDCA Access Factor, and HCCA Access Factor field values as described in 11.28.2.2.

11.28.3 HCCA TXOP negotiation

The procedures described in this subclause allow HCCA APs to cooperatively create new HCCA schedules that do not collide.

When sharing with at least one other HCCA AP, each sharing AP for which dot11RobustAVStreamingImplemented is true shall set its dot11HCCWmax to a value of at least 3.

HCCA APs that are able to directly exchange frames without the use of a third-party STA and signal support for unprotected or protected TXOP negotiation (as indicated by the Unprotected TXOP Negotiation or Protected TXOP Negotiation field equal to 1 in the Extended Capabilities element in Beacon frames) coordinate their TXOP schedules using HCCA TXOP Advertisement and HCCA TXOP Response frames. In this subclause, an HCCA AP in an OBSS that is able to directly exchange frames without the use of a third-party STA is referred to as a *collaboration candidate*.

The HCCA TXOP Update Count element is included in the Beacon frame to indicate that an HCCA TXOP schedule has changed. The Update Count field of the HCCA TXOP Update Count element is incremented (modulo 256) each time a TS with an access policy of HCCA or HEMM is created or deleted. An HCCA AP for which dot11PublicHCCATXOPNegotiationActivated is true or dot11ProtectedHCCATXOPNegotiationActivated is true shall advertise the Duration, Service Interval, and Start Time subfields for each HCCA TXOP reservation in a TXOP Reservation field as described in 9.4.1.44.

An HCCA AP for which dot11PublicTXOPNegotiationActivated is true or dot11ProtectedTXOPNegotiationActivated is true shall be able to maintain one or more dot11APCEEntry(s) for each collaboration candidate in the dot11APCTable. These fields indicate the schedules that the AP should try to avoid using when creating schedules for new TS requests.

Before accepting a TSPEC request that has the Access Policy subfield of the TSPEC element equal to “HCCA” or “HEMM,” an HC for which dot11PublicTXOPNegotiationActivated is true or dot11ProtectedTXOPNegotiationActivated is true should examine all dot11APCEEntry(s) that are present in the dot11APCTable.

When an AP with dot11PublicHCCATXOPNegotiationActivated true or with dot11ProtectedHCCATXOPNegotiationActivated true receives a TSPEC request that has the Access Policy subfield of the TSPEC element equal to “HCCA” or “HEMM,” it shall send an HCCA TXOP advertisement to each collaboration candidate. These HCCA TXOP advertisements shall have the TXOP Reservation field set to the TXOP that the AP is attempting to schedule.

An AP with dot11ProtectedTXOPNegotiationActivated true shall send the HCCA TXOP advertisement using a Protected HCCA TXOP Advertisement frame to each collaboration candidate that indicates support for protected HCCA TXOP negotiation (as indicated by the Protected TXOP Negotiation field equal to 1 in the Extended Capabilities element in Beacon frames from the collaboration candidate).

An AP with dot11PublicTXOPNegotiationActivated true shall send the HCCA TXOP advertisement using an HCCA TXOP Advertisement frame to each collaboration candidate that indicates support for unprotected HCCA TXOP negotiation (as indicated by the Unprotected TXOP Negotiation field equal to 1 in the Extended Capabilities element in Beacon frames from the collaboration candidate) unless the HCCA TXOP advertisement has already been transmitted to this collaboration candidate using a Protected HCCA TXOP Advertisement frame.

NOTE—When peer APs have both unprotected and protected TXOP negotiation activated, protected TXOP negotiation is used.

The AP shall not send an ADDTS Response frame to the requesting STA until one of the following conditions occurs:

- a) The AP has received an HCCA TXOP Response frame, with the Status field equal to “SUCCESS,” from all of the APs to which HCCA TXOP advertisements were sent.
- b) At least two Beacon frames have been received from all of the APs to which HCCA TXOP advertisements were sent.
- c) A Beacon frame containing the HCCA TXOP Update Count element is received from all of the APs to which HCCA TXOP advertisements were sent.
- d) A period of three dot11BeaconPeriod TU has elapsed.

If an AP receives another TSPEC request while waiting for one of the above conditions to occur, it shall delay processing this additional TSPEC request until one of the above conditions occurs.

An AP with dot11PublicTXOPNegotiationActivated false shall discard any received HCCA TXOP Advertisement frames. An AP with dot11ProtectedTXOPNegotiationActivated true shall discard any received unprotected HCCA TXOP Advertisement frames from a peer AP with which it has an active security association.

Upon reception of an unprotected HCCA TXOP Advertisement frame, an AP with dot11PublicTXOPNegotiationActivated true shall discard all dot11APCEntry(s) from the dot11APCTable that have dot11APCEntryMACAddress equal to the MAC address of the AP that sent the HCCA TXOP Advertisement frame and shall prepare a response using the procedures below.

An AP with dot11ProtectedTXOPNegotiationActivated false shall discard any received Protected HCCA TXOP Advertisement frames.

An AP with dot11ProtectedTXOPNegotiationActivated true that does not have an active security association with a peer AP that indicates support for protected HCCA TXOP negotiation shall use the AP PeerKey protocol (as defined in 12.11.2) and authenticated mesh peering exchange (AMPE) (as defined in 13.5) to negotiate security parameters and create a new SMKSA and STKSA to secure the Protected HCCA TXOP Advertisement frames. The use of AMPE proves possession of the PMK (generated using the procedures described in 12.11.2) and implicitly the private key that corresponds to the peer’s public key.

Upon reception of a valid Protected HCCA TXOP Advertisement frame, an AP with dot11ProtectedTXOPNegotiationActivated true shall discard all dot11APCEntry(s) from the dot11APCTable that have dot11APCEntryMACAddress equal to the MAC address of the AP that sent the Protected HCCA TXOP Advertisement frame and shall prepare a response using the procedures below.

If the (Protected) HCCA TXOP Advertisement frame has not been discarded due to the procedures above, the AP shall create a dot11APCEntry in the dot11APCTable for each TXOP reservation in the Active TXOP Reservations field of the (Protected) HCCA TXOP Advertisement frame.

If the (Protected) HCCA TXOP Advertisement frame has not been discarded due to the procedures above, the AP shall inspect its HCCA schedule to check whether the TXOP reservations number given in the Pending TXOP Reservations field of the HCCA TXOP Advertisement frame is in conflict with an existing accepted HCCA TXOP, allocated by itself. If there is no conflict, the AP shall send an HCCA TXOP Response frame with the Status field set to “SUCCESS” and create a dot11APCEEntry for each TXOP reservation in the Pending TXOP Reservations field in the HCCA TXOP Advertisement frame.

If the HCCA advertisement was sent using an unprotected Public Action frame, the HCCA TXOP response shall be sent using an unprotected Public Action frame.

If the HCCA advertisement was sent using a Protected HCCA TXOP Advertisement frame, the HCCA TXOP response shall be sent using a Protected HCCA TXOP Response frame.

If the AP detects that the TXOP given in the (Protected) HCCA TXOP Advertisement frame is in conflict with an existing accepted HCCA TXOP and this AP is not itself currently processing an ADDTS request, it shall send a (Protected) HCCA TXOP Response frame with the Status field set to “TS_SCHEDULE_CONFLICT,” the Alternate Schedule field set to a period of time that does not conflict with any currently accepted HCCA TXOPs, and the Avoidance Request field absent. The Duration subfield of the Alternate Schedule field should be greater than or equal to the Duration subfield of the Schedule field in the (Protected) HCCA TXOP Advertisement frame. The Duration subfield of the Alternate Schedule field may be less than the Duration subfield of the Schedule field in the (Protected) HCCA TXOP Advertisement frame when there is an insufficient period of time that does not conflict with currently accepted HCCA TXOPs.

If the AP detects that the TXOP given in the (Protected) HCCA TXOP Advertisement frame is in conflict with an in-progress ADDTS request for an HCCA TXOP for which HCCA TXOP Response frames have not been received, it shall send a (Protected) HCCA TXOP Response frame with the Status field set to “TS_SCHEDULE_CONFLICT” and the Alternate Schedule and Avoidance Request fields set according to the following rules:

- If $\text{MIX}(\text{MAC}_r) < \text{MIX}(\text{MAC}_i)$, the Alternate Schedule field is set to a value that does not conflict with any accepted HCCA TXOPs and also does not conflict with the TXOP of the in-progress ADDTS request. The Avoidance Request field is set to the TXOP of the in-progress ADDTS request.
- If $\text{MIX}(\text{MAC}_r) > \text{MIX}(\text{MAC}_i)$, the Alternate Schedule field is set to the value from the TXOP Reservation field from the HCCA TXOP Advertisement frame. The Avoidance Request field is set to a time period that does not conflict with any accepted HCCA TXOPs nor the TXOP in the Alternate Schedule field and has sufficient duration and service interval to meet the requirements of the in-progress ADDTS request.

where

- MAC_r is the MAC address of the AP that received the HCCA TXOP Advertisement frame
 MAC_i is the MAC address of the AP that sent the HCCA TXOP Advertisement frame

The MIX function takes the 6 octets of a MAC address and computes a new 6 octet value:

$$\text{MIX}(\text{MAC}) = \text{MAC}[4] \parallel \text{MAC}[5] \parallel \text{MAC}[0] \parallel \text{MAC}[1] \parallel \text{MAC}[2] \parallel \text{MAC}[3]$$

For the purpose of the comparisons shown above, the resulting 6 octet value is converted to a positive integer treating the first octet as the most significant octet of the integer.

Table 11-19 provides a summary of the values used in an HCCA TXOP Response frame.

Table 11-19—Contents of HCCA TXOP Response frame

| Case | Status code | Alternate Schedule field | Avoidance Request field |
|--|----------------------|--|---|
| No conflict with existing or in-progress schedules | SUCCESS | Not present | Not Present |
| Conflicts with existing schedule; no ADDTS request in progress | TS_SCHEDULE_CONFLICT | Period of time that does not conflict with any currently accepted HCCA TXOPs | Not Present |
| Conflict with in-progress schedules, $\text{MIX}(\text{MAC}_r) < \text{MIX}(\text{MAC}_i)$ | TS_SCHEDULE_CONFLICT | Period of time that does not conflict with any currently accepted HCCA TXOPs nor the in-progress ADDTS request | Schedule of in-progress ADDTS request |
| Conflict with in-progress schedules, $\text{MIX}(\text{MAC}_r) > \text{MIX}(\text{MAC}_i)$ | TS_SCHEDULE_CONFLICT | Same schedule that was in the HCCA TXOP Advertisement frame | Period of time that does not conflict with any currently accepted HCCA TXOPs nor the period given in the Alternate Schedule field |

The AP shall keep a record of the TXOP proposed in the Alternate Schedule field in a TXOP avoidance record and should avoid scheduling any new HCCA TXOPs in this proposed period until any of the following conditions occurs:

- A period of $\text{dot11HCCATXOPBeaconTimeout}$ multiplied by dot11BeaconPeriod TUs has elapsed.
- The AP with $\text{dot11PublicTXOPNegotiationActivated}$ true receives an unprotected HCCA TXOP Advertisement frame from the AP to which the unprotected HCCA TXOP Response frame was sent.
- The AP with $\text{dot11ProtectedTXOPNegotiationActivated}$ true receives a Protected HCCA TXOP Advertisement frame from the AP to which the Protected HCCA TXOP Response frame was sent.

If an AP with $\text{dot11PublicTXOPNegotiationActivated}$ true receives an unprotected HCCA TXOP Response frame with the Status field equal to “TS_SCHEDULE_CONFLICT,” the AP should create a new schedule for the TSPEC request using the suggestion provided in the HCCA TXOP Response frame. If an AP with $\text{dot11ProtectedTXOPNegotiationActivated}$ true receives a Protected HCCA TXOP Response frame with the Status field equal to “TS_SCHEDULE_CONFLICT,” the AP should create a new schedule for the TSPEC request using the suggestion provided in the Protected HCCA TXOP Response frame.

If an AP creates a new schedule in response to a (Protected) HCCA TXOP Response frame, it shall send a new HCCA TXOP advertisement to each collaboration candidate, using the procedures previously defined in this subclause.

After one or more HCCA TXOP Advertisement frame transmissions that cause the reception of an HCCA TXOP Response frame with the Status field equal to “TS_SCHEDULE_CONFLICT,” the AP may terminate the HCCA TXOP advertisement procedure and respond to the ADDTS Request frame with a status code not equal to SUCCESS (decline the ADDTS Request) or a status code equal to SUCCESS (accept the ADDTS request regardless of potential HCCA TXOP conflicts).

11.28.4 HCCA AP timing synchronization for HCCA TXOP advertisement

11.28.4.1 General

HCCA APs in OBSSs for which `dot11PublicHCCATXOPNegotiationActivated` is true or `dot11ProtectedHCCATXOPNegotiationActivated` is true synchronize their TSF timing so that the HCCA TXOP advertisement scheme does not suffer from time differences between the clocks of the overlapping APs.

In order to use HCCA TXOP advertisement, the AP maintains synchronization with its APs in OBSSs. HCCA APs that use HCCA TXOP advertisement shall use a DTIM interval with a duration of $2^n \times 100$ TU where n a non-negative integer less than or equal to 5.

NOTE—The DTIM interval of the form $2^n \times 100$ TU has been chosen to facilitate the verification that HCCA TXOP reservations do not overlap. The restriction that n be less than or equal to 5 has been chosen so that the range of the HCCA TXOP start time in the reservation (see 9.4.1.44) is compatible with the maximal DTIM interval length.

11.28.4.2 Timing offset

An HCCA AP with `dot11PublicHCCATXOPNegotiationActivated` true or `dot11ProtectedHCCATXOPNegotiationActivated` true shall update the timing offset value based on time stamps from the received Beacon frames from HCCA APs that have an entry in the `dot11APCTable`. The timing offset value is calculated using Equation (11-7).

$$T_{\text{offset}} = T_T - T_R \quad (11-7)$$

where

T_{offset} is the timing offset value

T_T is the value in the Timestamp field in the received Beacon frame from the overlapping HCCA AP

T_R is the Beacon frame reception time measured using the HCCA AP's TSF timer

The offset value is represented as 2s complement. The unit of the offset value is microseconds. The HCCA AP shall keep the T_{offset} value calculated from the latest Beacon frame received from each AP in an OBSS.

11.28.4.3 Clock drift adjustment

When `dot11RobustAVStreamingImplemented` is true and `dot11PublicHCCATXOPNegotiationActivated` is true, the HCCA AP shall examine the reception time of the Beacon frames from overlapping HCCA APs with which it maintains synchronization and adjust its TSF timer to compensate the relative timing error among overlapping HCCA APs caused by the clock drift. The HCCA AP adjusts its TSF so that its TSF counting frequency is aligned to the AP with the lowest TSF counting frequency.

The HCCA AP shall operate the following clock drift compensation procedure:

- a) If the HCCA AP does not have a valid T_{offset} value obtained from the previous Beacon frame reception from a particular overlapping HCCA AP, it shall not operate the clock drift compensation for that AP.
- b) When the HCCA AP receives a Beacon frame from one of the overlapping HCCA APs with which it maintains synchronization, the HCCA AP shall calculate the clock drift amount $T_{\text{ClockDrift}}$ by comparing the T_{offset} obtained previously for this overlapping HCCA AP and the T_{offset} obtained from the Beacon frame reception. See Equation (11-8).

$$T_{\text{ClockDrift}} = T_{\text{offset},1} - T_{\text{offset},0} \quad (11-8)$$

where

$T_{ClockDrift}$ is the clock drift amount represented as 2s complement, in microseconds

$T_{offset,1}$ is the T_{offset} obtained from the previous reception

$T_{offset,0}$ is the T_{offset} obtained from the current frame reception

- c) The HCCA AP shall calculate the $T_{ClockDrift}$ value for all overlapping HCCA APs with which it maintains synchronization and select the largest $T_{ClockDrift}$ value. If the largest $T_{ClockDrift}$ is greater than zero, it shall suspend its TSF timer for the duration of the largest $T_{ClockDrift}$. The HCCA AP shall suspend its TSF timer frequently enough that the delay during a single beacon period does not exceed 0.08% of its beacon interval.

NOTE—This clock drift compensation procedure is not intended to maintain a strict synchronization. It aims to stop TBTT drifting away among overlapping HCCA APs to allow some jitter of TSF timer.

11.29 DMG beamformed link and BSS maintenance

11.29.1 Beamformed link maintenance

A pair of DMG STAs that have established a beamformed link can maintain this link. This subclause describes procedures that allow a pair of DMG STAs to maintain a beamformed link that was established between them.

A beamformed link is established as a result of the most recent success of the procedures specified in 10.38.2 if the STAs completed the SLS phase or as a result of the most recent success of the procedures specified in 10.38.6.4 if the STAs completed the BRP phase.

A DMG STA shall negotiate the value of dot11BeamLinkMaintenanceTime using the procedures specified in 10.38.6.2 or may leave it undefined as specified in 9.5.6.

If the dot11BeamLinkMaintenanceTime has been defined as described in 9.5.6, a DMG STA shall implement a beam link maintenance timer to control each beamformed link. The STA shall keep one beam link maintenance timer per beamformed link. After it is set, the beam link maintenance timer shall count down. The timer shall be stopped when it reaches the value zero. The beam link maintenance timer of a beamformed link shall be halted during the following periods of time:

- BTI and A-BFT of a beacon interval
- SPs and CBAPs in which the STA does not participate
- When any of the STAs involved in the beamformed link is in doze state

The beam link maintenance timer shall be set to dot11BeamLinkMaintenanceTime when the source DMG STA and destination DMG STA successfully complete the BRP if the beam refinement phase is performed (10.36.3) or the source DMG STA and destination DMG STA successfully complete the SLS (10.38.2) if the beam refinement phase is skipped as defined in 10.36.3.

A DMG AP or PCP shall set the beam link maintenance timer to dot11BeamLinkMaintenanceTime when it receives a response from the non-AP and non-PCP DMG STA during the ATI or when it receives an SPR frame as a response to a Poll frame, if these frames are received using the beamformed link established with the non-AP and non-PCP DMG STA.

The non-AP and non-PCP DMG STA shall set the beam link maintenance timer to the dot11BeamLinkMaintenanceTime when it receives a request from the DMG AP or PCP during the ATI or when it receives a Poll or a Grant frame, if these frames are received using the beamformed link established with the DMG AP or PCP.

The initiator DMG STA shall set the beam link maintenance timer to the dot11BeamLinkMaintenanceTime when an immediate response or acknowledgment (Ack, BlockAck, DMG CTS, DMG DTS) has been received from the recipient DMG STA of the beamformed link.

The recipient DMG STA shall set the beam link maintenance timer to the dot11BeamLinkMaintenanceTime after the transmission of the immediate response or acknowledgment (Ack, BlockAck, DMG CTS, DMG DTS) has been completed to the initiator DMG STA of the beamformed link.

To prevent expiration of the beam link maintenance timer when a DMG STA does not have MSDUs to send, the STA shall transmit QoS Null frames to maintain a beamformed link.

Following the expiration of the beamlink maintenance time (specified by the current value of dot11BeamLinkMaintenanceTime), the destination DMG STA of the SP shall configure its receive antenna to a quasi-omni antenna pattern for the remainder of the SP and during any SP following the expiration of the beamlink maintenance time.

Any time after dot11BeamLinkMaintenanceTime has elapsed, the source DMG STA of the SP may initiate an ISS to restore the beamformed link with the destination DMG STA of the SP following the rules defined in 10.38.2. The source DMG STA may initiate the ISS before expiration of dot11BeamLinkMaintenanceTime.

The responder DMG STA of the beamformed link in the CBAP shall configure its receive antenna to a quasi-omni antenna pattern following the expiration of dot11BeamLinkMaintenanceTime except when it is involved in a frame exchange with another STA.

Any time after dot11BeamLinkMaintenanceTime has elapsed, the initiator DMG STA of the beamformed link in the CBAP may initiate an ISS to restore the beamformed link with the responder STA following the rules defined in 10.38.2. The initiator STA may initiate the ISS before expiration of dot11BeamLinkMaintenanceTime.

If a DMG STA detects degradation in the link quality between itself and another STA, the STA can use beam tracking or beam refinement to improve the link quality. The STA can request the AP or PCP to schedule an SP to perform BF with the other STA or use a CBAP to perform BF. The STA can use the A-BFT to perform BF if the other STA is its AP or PCP. A DMG AP or PCP can perform BF with a non-AP and non-PCP STA during a CBAP or by scheduling an SP between the AP or PCP and the non-AP and non-PCP STA through an Extended Schedule element transmitted in a DMG Beacon or Announce frame.

If the link quality between a DMG AP or PCP and a non-AP and non-PCP DMG STA degrades, but the STA can still receive DMG Beacon frames with the Next A-BFT field equal to 0, the STA should improve the link quality by performing RSS during the A-BFT period as described in 10.38.5.

A DMG STA may use the value of the parameter LAST_RSSI in the RXVECTOR of a received frame to decide to initiate beamforming with a peer STA if the value of the LAST_RSSI parameter is different from zero (10.3.2.3.3).

Figure 11-42 illustrates the operation of the beam link maintenance timer for an example involving STA-A and STA-B. In beacon interval n , STA-A and STA-B successfully perform beamforming and set up the beam link maintenance timer. In beacon interval $n+1$, the STAs have two SPs established between them. The beam link maintenance timer is halted and released according to the rules described above. Once the timer beam link maintenance timer expires, the STAs redo beamforming.

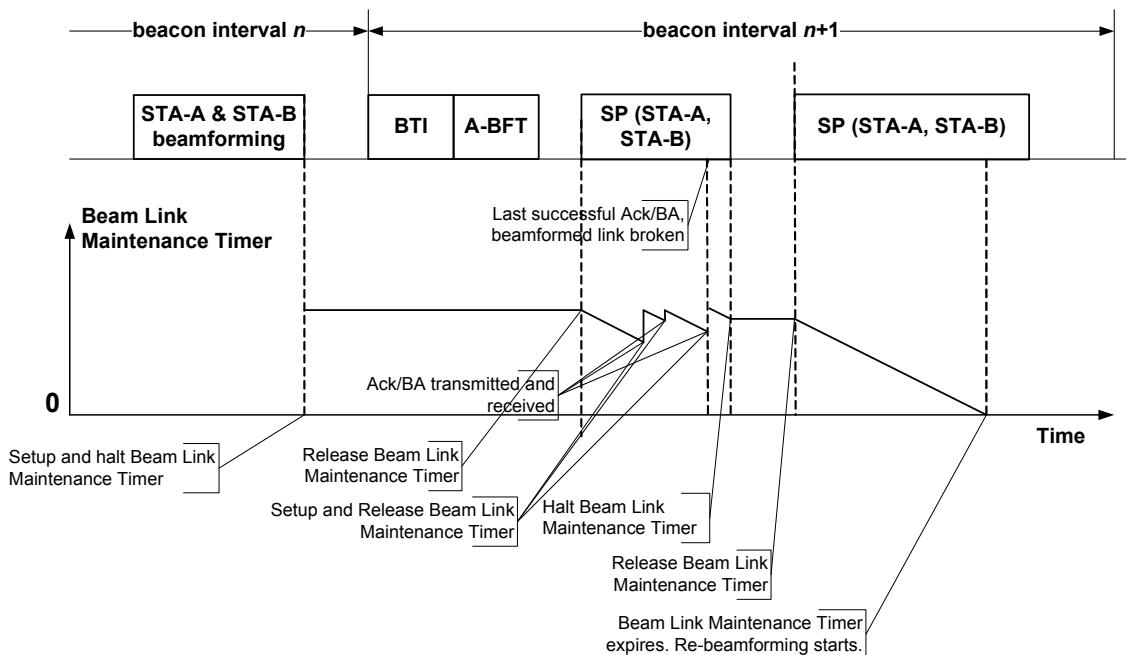

Figure 11-42—Example of beamformed link maintenance

11.29.2 PCP Handover

11.29.2.1 General

A STA is PCP handover capable if the PCP Handover field in the STA's DMG Capabilities element (9.4.2.128) is 1. The STA is PCP handover incapable otherwise.

The PCP handover process allows the information pertinent to the operation of the PBSS to be distributed to suitable PCP handover capable STA(s) and for a PCP handover capable STA to take over the PCP responsibilities from the PCP explicitly or implicitly.

The information pertinent to the operation of a PBSS includes STA information and pseudo-static scheduling information.

The STA information comprises the STA's AID, MAC address, and DMG Capabilities element. The PCP may relay the information to all STAs in the PBSS by using the Information Response frame.

The pseudo-static scheduling information comprises pseudo-static SP and CBAP allocations carried in the Extended Schedule element (9.4.2.132).

A PCP handover capable STA supports two types of PCP Handover, explicit and implicit. In explicit PCP handover, the PCP explicitly selects and schedules the transfer of PCP responsibilities to another PCP handover capable STA as described in 11.29.2.2. In implicit PCP handover the PCP distributes the Next PCP List element (9.4.2.140) in its DMG Beacon or Announce frames and maintains the content of the NextPCP List element to facilitate the implicit handover process described in 11.29.2.3. The PCP may determine the priority of next PCPs and update the next PCP list based on information contained within a STA's DMG Capabilities element.

If there is at least one PCP handover capable STA in the PBSS, the NextPCP List element contains an ordered list of one or more PCP handover capable STAs that can take over the role of the PCP during implicit handover. The ordering of STAs in the NextPCP List is specified in decreasing priority order and the criteria for updating the NextPCP List are implementation specific. The PCP shall increment the Token field of the NextPCP List by 1 every time the list is changed. If there are no PCP handover capable STAs in the PBSS, the length of the NextPCP List element is 0, and implicit PCP handover cannot be performed.

When a PCP handover capable STA takes over the PCP responsibilities of a PBSS, the pseudo-static scheduling information shall remain unchanged. Any outstanding request for resource allocation is lost and STAs that have outstanding requests for allocation may re-request the resource allocation.

In explicit PCP handover, the PCP shall use the value of the PCP factor when selecting the candidate PCP (see 11.1.4.3.6).

Following a PCP handover, a non-PCP STA shall attempt to transmit a frame to the new PCP within dot11MaxLostBeacons beacon intervals. If the new PCP does not receive at least one frame from an associated non-PCP STA for dot11MaxLostBeacons beacon intervals following a PCP handover, it should disassociate the STA from the PBSS.

11.29.2.2 Explicit handover procedure

The PCP may transmit a Handover Request frame to a non-PCP STA that is handover capable. Upon receiving a Handover Request, a non-PCP STA becomes the candidate PCP. If the handover request is accepted, the candidate PCP shall transmit a Handover Response frame to the PCP with the Handover Result field set to 0. If the handover request is rejected, the candidate PCP shall transmit a Handover Response frame to the PCP with the Handover Result field set to 1, 2, or 3 and cease to be the candidate PCP.

A non-PCP STA that is handover capable may transmit a Handover Request frame to the PCP of the PBSS if the PCP is handover capable. Upon transmission of the Handover Request frame, the non-PCP STA becomes the candidate PCP. If the handover request is accepted, the PCP shall transmit a Handover Response frame to the candidate PCP with the Handover Result field set to 0. If the handover request is rejected, the PCP shall transmit a Handover Response frame to the candidate PCP with the Handover Result field set to 1, 2, or 3, and the candidate PCP shall cease to be a candidate PCP.

Following the transmission or reception of a successful Handover Response frame, a candidate PCP should request STA information and pseudo-static scheduling information from the PCP using an Information Request frame within the next dot11NbrOfChangeBeacons beacon intervals. The candidate PCP should also request SPs to perform beamforming and, if appropriate, establish a security association with other associated STAs prior to the completion of PCP handover.

Following the reception or transmission of a Handover Response frame, the PCP shall transmit a PCP Handover element within every DMG Beacon or Announce frame for each of the next dot11NbrOfChangeBeacons beacon intervals with the Old BSSID field set to the BSSID of the PBSS, the New PCP Address field set to the MAC address of the candidate PCP, and the Remaining BIs field set to the number of beacon intervals remaining until the candidate PCP takes over the role of PCP for the PBSS. The initial value of the Remaining BIs field shall be equal to the Remaining BI field value last transmitted by the PCP in a Handover Request frame to the candidate PCP or equal to the Remaining BI field value last received by the PCP in a Handover Request frame from the candidate PCP, whichever is later. A non-PCP STA receiving a DMG Beacon or Announce frame containing the PCP Handover element shall set the STA's local countdown counter to the value of the Remaining BIs field contained in the PCP Handover element. The STA shall then decrease the local countdown counter by one at each TBTT, and shall use the candidate PCP's address contained in the New PCP Address field within the PCP Handover element as the new beacon filter address once the STA's local countdown reaches zero. When the countdown timer equals zero, the candidate PCP shall assume the role of PCP.

11.29.2.3 Implicit handover procedure

Upon receiving the NextPCP List element, a PCP handover capable STA that finds its AID as the AID entry i in the NextPCP List element received from the PCP becomes the implicit candidate PCP i . Upon detecting a Token value contained in the NextPCP List element that is different from the value of the last Token received from the PCP, each implicit candidate PCP should request STA information and pseudo-static scheduling information from the PCP by transmitting an Information Request frame addressed to the PCP (11.30.1).

The implicit handover process is triggered at the implicit candidate PCP i when the implicit candidate PCP i fails to receive a DMG Beacon or Announce frames from the PCP for $(i \times \text{dot11ImplicitHandoverLostBeacons})$ beacon intervals. When triggered, the implicit candidate PCP i shall send at least one DMG Beacon frame during each of the next $\text{dot11MaxLostBeacons}$ BTIs if the following conditions are met:

- No DMG Beacon or Announce frames are received from the PCP.
- No DMG Beacon frame carrying a PCP Handover element with the value of the Old BSSID field equal to the BSSID of the PBSS is received from an implicit candidate PCP with a smaller index on the NextPCP List.

Each DMG Beacon frame sent by the implicit candidate PCP i shall contain a PCP Handover element with the Old BSSID field set to the BSSID of the PBSS from which control is being taken, i.e., the previous PBSS, the New PCP Address field set to its MAC address, and the Remaining BIs field initially set to $\text{dot11MaxLostBeacons}$ and decremented by 1 at each TBTT. A member non-PCP STA of the PBSS, after failing to receive a DMG Beacon or Announce frame for $\text{dot11MaxLostBeacons}$ beacon intervals, should associate with the new PCP sending a DMG Beacon frame containing the PCP Handover element with Old BSSID field equal to the BSSID of the previous PBSS and the smallest Remaining BIs field value. The implicit candidate PCP that successfully transmits a DMG Beacon frame with the Remaining BIs field within the PCP Handover element equal to 0 completes the implicit handover by scheduling, if appropriate, pseudo-static SPs between its member STAs following the pseudo-static scheduling information it obtained from the previous PBSS.

To avoid disruptions to pseudo-static SPs due to implicit handover, the value of $\text{dot11ImplicitHandoverLostBeacons}$ should be lower than $\text{dot11MaxLostBeacons}$.

11.30 DMG BSS peer and service discovery

11.30.1 Information Request and Response

A STA may request information about either a single STA in the BSS or about all of the STAs in the BSS by sending an Information Request frame (9.6.20.4). If the STA is requesting information about only a single STA in the BSS, it shall set the Subject Address field in the Information Request frame to the MAC address of that STA. If the STA is requesting information about all of the STAs in the Infrastructure BSS and PBSS, it shall set the Subject Address field in the Information Request frame to the broadcast address and shall transmit the Information Request frame to the AP and PCP.

A STA may transmit an Information Request frame with the Length field of the Request element set to 0 and with no Extended Request element present to another STA in the BSS to determine if the destination DMG STA is still present in the PBSS and is within range of the sending STA.

A STA may transmit an Information Request frame including its STA Capability element and other elements. A non-PCP and non-AP STA shall not include in the Information Request frame the capability information corresponding to another STA.

The STA may transmit an Information Response frame (9.6.20.4) either unsolicited or as a response to an Information Request frame. If a STA is providing information about a single STA in the BSS, it shall set the Subject Address field in the Information Response frame to the MAC address of that STA. If a STA is providing information about all of the STAs in the PBSS, it shall set the Subject Address field in the Information Response frame to the broadcast address.

A STA processes a received Information Request frame as follows:

- Each element that is listed in a Request element or Extended Request element and that is supported by the STA shall be included in the Information Response frame. An element that is listed in a Request element or Extended Request element and that is not supported by the STA shall not be included.
- If dot11RadioMeasurementActivated is true and the RCPI element was requested, an RCPI element containing the RCPI of the Probe Request frame shall be included. If no measurement result is available, the RCPI value shall be set to indicate “Measurement not available” (see Table 9-154).
- If dot11RadioMeasurementActivated is true and the RSNI element was requested, an RSNI element containing the RSNI of the Probe Request frame shall be included. If no measurement result is available, the RSNI value shall be set to indicate that a measurement is not available (see 9.4.2.41).

A STA shall send an Information Response frame with no requested or provided elements in response to a received Information Request frame that solicits information about a single target STA, as identified by the Subject Address field within the Information Request frame, if

- The target STA is not a member of the PBSS and the STA sending the Information Response frame is the PCP of the PBSS, or AP of the Infrastructure BSS and PBSS, or
- The STA sending the Information Response frame is a non-PCP and non-AP STA and is not the target STA.

In all other cases, the STA shall send the Information Response frame with the information requested by the requesting STA.

11.30.2 Peer Service Discovery

An AP or PCP may provide different types of information to a non-AP and non-PCP STA upon request. To query available services in a BSS, a non-AP and non-PCP STA shall send either an Information Request frame or a Probe Request frame to the AP or PCP (11.30.1). The Information Request and Information Response frames are robust Management frames, while the Probe Request and Probe Response frames are not.

Upon receiving the Information Request frame, the AP or PCP shall respond with an Information Response frame only if all of the following three criteria are true:

- a) The SSID in the Information Request frame is the wildcard SSID or the specific SSID of the AP or PCP.
- b) The BSSID field in the Information Request frame is the wildcard BSSID or the BSSID of the AP or PCP.
- c) The DA field in the Information Request frame is the MAC address of the AP or PCP.

The AP or PCP transmits the Information Response frame to the address of the non-AP and non-PCP STA that generated the Information Request.

The Information Response frame may include vendor-specific elements.

11.31 Changing DMG BSS parameters

11.31.1 General

This subclause describes the methods used by the AP or PCP to change certain key characteristics of the BSS. It also describes a method for a non-AP and non-PCP STA to make a recommendation on those characteristics to the AP or PCP.

The AP or PCP delivers the DMG BSS Parameter Change element to STAs holding pseudo-static SPs and STAs in power save mode before a DMG BSS parameter change.

The AP or PCP shall initiate a DMG BSS parameter change by including a DMG BSS Parameter Change element (9.4.2.127) in its DMG Beacon or Announce frames. The AP or PCP places the DMG BSS Parameter Change element in every DMG Beacon or Announce frame after the DMG BSS Parameter Change element is first included in the frame, stopping in the DMG Beacon or Announce frame immediately after the DMG BSS parameter change takes effect.

11.31.2 Moving the TBTT

The AP or PCP may move the TBTT and hence move the entire beacon interval. Moving the beacon interval means that except for the beacon interval in which the change takes effect, the beacon interval duration is unchanged while the position of the TBTT is moved.

The TBTT shall not be moved by an amount that is larger than the value in the Beacon Interval field present in DMG Beacon and Announce frames in which the DMG BSS Parameter Change element is sent.

To move the TBTT to an intended new TBTT, the AP or PCP shall insert the DMG BSS Parameter Change element in DMG Beacon frames and/or Announce frames with the Move field set to 1 (9.4.2.127). The DMG Beacon frames and/or the Announce frames containing the DMG BSS Parameter Change element shall be sent at each TBTT dot11NbrOfChangeBeacons times before the TBTT is changed as indicated in the TBTT offset field.

At each transmission of the DMG BSS Parameter Change element, the TBTT Offset field shall be set to a value equal to the lower order 4 octets of the intended new TBTT.

The value of dot11NbrOfChangeBeacons shall be greater than dot11MaxLostBeacons.

NOTE—As defined in 11.1.2.1, the PCP transmits at least one DMG Beacon frame to each associated STA within a time interval that is not longer than dot11BeaconPeriod × dot11MaxLostBeacons TUs.

Announce frames shall be used to deliver the DMG BSS Parameter Change element to all STAs participating in pseudo-static SPs.

The value of the Beacon Interval field of DMG Beacon frames and the Announce frames sent at the dot11NbrOfChangeBeacons+1 TBTT shall be set to the difference of the intended new TBTT and the TBTT where the DMG Beacon or Announce frames were sent.

STAs associated with an AP or PCP that moves the TBTT shall not transmit during the beacon interval that precedes a new TBTT if the transmission time ends at the TBTT or later, even if the SP or the CBAP were scheduled in the beacon interval.

At the intended new TBTT that is dot11NbrOfChangeBeacons+2 TBTTs after the DMG BSS Parameter Change element is first transmitted, the TSF timer is reset to 0 as defined in 11.1.3.3.

An AP or PCP member of an AP or PCP cluster that wishes to move its TBTT shall set the TBTT Offset field to an empty Beacon SP allocated by its S-AP or S-PCP as defined in 10.37.

Figure 11-43 illustrates the process in moving the TBTT position.

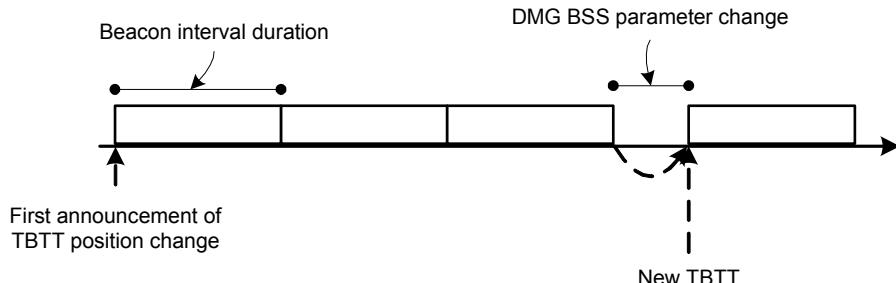

Figure 11-43—Moving the TBTT position

11.31.3 Changing beacon interval duration

The AP or PCP may change the duration of its beacon interval during the BSS operation.

To change its beacon interval, the AP or PCP shall insert the DMG BSS Parameter Change element into DMG Beacon frames and/or Announce frames with the Size field set to 1 and the BI Duration field set to the duration of the beacon interval following this DMG BSS parameter change. The TBTT Offset field shall be set to the lower order 4 octets of the TBTT at dot11NbrOfChangeBeacons+1 TBTT position when this DMG BSS parameter change takes effect.

The DMG Beacon frames and/or the Announce frames shall be sent at each TBTT dot11NbrOfChangeBeacons times before the beacon interval is changed as indicated in the BI Duration field of the DMG BSS Parameter Change element.

At each transmission of the DMG BSS Parameter Change element the TBTT Offset field shall be set to a value equal to the lower order 4 octets of the intended TBTT.

The value of dot11NbrOfChangeBeacons shall be greater than dot11MaxLostBeacons.

Announce frames shall be used to deliver the DMG BSS Parameter Change element to all STAs participating in pseudo-static SPs.

The AP or PCP that shortens the beacon interval shall not schedule SP and CBAP allocations that use more time than allowed in the beacon interval indicated in the BI Duration field of the DMG BSS Parameter Change element.

The value of the beacon interval shall be set to the BI Duration field of the DMG BSS Parameter Change element at the dot11NbrOfChangeBeacons+1 TBTT. At this TBTT, the TSF timer is reset to 0 as defined in 11.1.3.3.

If the AP or PCP sets the Move and the Size fields to 1 in the same DMG BSS Parameter Change element, it shall set the TBTT Offset field and proceed as defined in 11.31.2. The value of the beacon interval shall be set to the BI Duration field of the DMG BSS Parameter Change element at the new TBTT as defined in 11.31.2.

Figure 11-44 illustrates the process in changing the beacon interval duration.

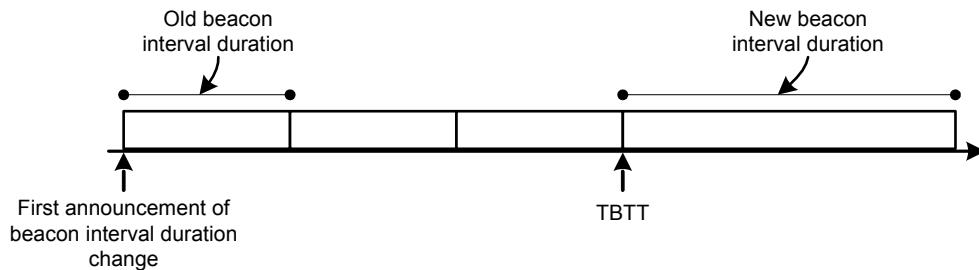

Figure 11-44—Changing beacon interval duration

11.31.4 Maintaining synchronization in an AP or PCP cluster

A S-AP or S-PCP shall update the Clustering Control field transmitted in the DMG Beacon frame if the DMG BSS parameter change modifies the allocation of the Beacon SPs (10.37). If the Clustering Control field is modified as a result of a DMG BSS parameter change, the S-AP or S-PCP shall transmit the updated Clustering Control field in every DMG Beacon frame in which the DMG BSS Parameter Change element is transmitted.

An AP or PCP member of an AP or PCP cluster receiving a S-AP or S-PCP DMG Beacon frame with a DMG BSS Parameter Change element indicating a change in the beacon interval duration or TBTT time shall immediately insert the appropriate DMG BSS Parameter Change element into its DMG Beacons if the S-AP or S-PCP's DMG BSS parameter change causes a modification in the allocation of the Beacon SPs.

If an AP or PCP is required to change the beacon interval or/and TBTT to participate in an AP or PCP cluster or to change the beacon interval or/and TBTT as a result of its S-AP's or S-PCP's parameters change (see 10.37), it shall follow the procedures in 11.31.2 and 11.31.3.

11.31.5 Recommending DMG BSS parameters to the AP or PCP

A non-AP and non-PCP STA may make a recommendation for DMG BSS parameters to the AP or PCP by including a DMG BSS Parameter Change element in an Information Request or Information Response frame sent to the AP or PCP.

A non-AP and non-PCP STA may recommend a shift in TBTT by setting the Move subfield in the Change Type Bitmap field of the DMG BSS Parameter Change element to 1 and setting the TBTT Offset field to the lower order 4 octets of the non-AP and non-PCP STA's TSF timer at the recommended first changed TBTT. The non-AP and non-PCP should select a value for the TBTT Offset field that gives the AP or PCP enough time to exercise the change. Similarly, a non-AP and non-PCP STA may recommend a beacon interval duration to the AP or PCP by setting the Size subfield in the Change Type Bitmap field of the DMG BSS Parameter Change element to 1 and setting the BI Duration field to the recommended beacon interval duration in TUs.

An AP or PCP that receives an Information Request frame or an unsolicited Information Response frame from a non-AP and non-PCP STA containing a DMG BSS Parameter Change element may use the information within the element to change the DMG BSS parameters. When receiving an Information Request frame that includes the DMG BSS Parameter Change element, AP or PCP responds with an Information Response frame as specified in 11.30.1. If the AP or PCP changes the BSS parameters in the transmitted Information Response frame, the AP or PCP shall include a DMG BSS Parameter Change element reflecting the BSS parameter changes and shall use the procedure defined in 11.31.2 and 11.31.3, as appropriate, to change the BSS parameters. If the AP or PCP decides not to change the BSS parameters, it shall not include a DMG BSS Parameter Change element in the transmitted Information Response frame.

11.32 Spatial sharing and interference mitigation for DMG STAs

11.32.1 General

This subclause describes mechanisms to enable spatial sharing and interference mitigation within a PBSS/infrastructure BSS and in a uncoordinated OBSS environment.

Spatial sharing mechanisms allow SPs belonging to different STAs in the same spatial vicinity to be scheduled concurrently over the same channel, and for interference mitigation. Alternatively, the AP or PCP can use CBAPs to mitigate interference.

The SPSH and Interference Mitigation field in the DMG Capabilities element indicates whether a STA supports spatial sharing.

A STA that supports spatial sharing, as indicated in the SPSH and Interference Mitigation field equal to 1 in the STA's DMG Capabilities element, shall support the directional channel quality measurements described in 9.4.2.21.16 and 9.4.2.22.15.

11.32.2 Spatial sharing and interference assessment

The AP or PCP should request STAs to perform and report spectrum and radio resource measurements described in 11.11 to assess the possibility to perform spatial sharing and for interference mitigation.

The AP or PCP should use the directional channel quality described in 9.4.2.21.16 and 9.4.2.22.15 to assess the possibility for spatial sharing of SPs.

An SP to be assessed for spatial sharing with other scheduled (existing) SPs or considered to be reallocated in the beacon interval is hereby termed as a candidate SP. There might be multiple candidate and existing SPs at one time, and an SP may simultaneously assume the role of candidate and existing SP depending upon the context it is used for spatial sharing and interference assessment.

STAs that participate in an SP and that support spatial sharing should perform beamforming training with each other before engaging in any other communication or performing any measurements described in this subclause.

The AP or PCP should request source DMG STA and destination DMG STA involved in a candidate SP to perform measurements for the purpose of spatial sharing with an existing SP only after the STAs have beamforming trained with each other. The AP or PCP can infer that the STAs in a candidate SP have a beamformed link with each other if the Beamforming Training field within the DMG TSPEC used to set up the candidate SP was set to 1 and at least one beacon interval has elapsed since the candidate SP was first scheduled.

If the AP or PCP transmits a Directional Channel Quality request to a STA involved in a candidate SP to assess the possibility for spatial sharing with another existing SP, it shall set the Target STA to the corresponding peer STA's MAC address involved in the candidate SP and shall set the Measurement Method field to indicate ANIPI.

If the candidate SP has already been allocated channel time, the AP or PCP should additionally transmit a Directional Channel Quality request to the STAs involved in the existing SP to assess the possibility for spatial sharing with the candidate SP. In the Directional Channel Quality request, the AP or PCP shall set the Target STA to the corresponding peer STA involved in the existing SP and shall set the Measurement Method field to indicate ANIPI.

NOTE—When the AP or PCP transmits a Directional Channel Quality request to a STA of an existing SP, it intends to assess the channel quality during transmission by STAs belonging to the candidate SP. Similarly, when the AP or PCP transmits a Directional Channel Quality request to a STA of a candidate SP, it intends to assess the channel quality during transmission by STAs belonging to the existing SP.

If a recipient STA that receives a Directional Channel Quality request frame is already beamformed trained with the target STA specified by the AID field within the frame, then the recipient STA shall carry out the measurement employing the same receive antenna configuration as is used by the recipient STA when receiving frames from the target STA. If the AID field is set to the broadcast AID or an unknown AID, then the recipient STA shall perform the measurements using a quasi-omni antenna pattern.

Figure 11-45 illustrates an example of spatial sharing assessment between two SPs. In this example, SP1 is the existing SP and SP2 is the candidate SP. The AP or PCP transmits a Directional Channel Quality request to STAs C and D to measure over SP1’s channel allocation, and transmits a Directional Channel Quality request to STAs A and B to measure over SP2’s channel allocation. The relation of the Measurement Start Time and Measurement Duration fields in the Directional Channel Quality request message is shown in Figure 11-45, while the field Number of Time Blocks is the ratio (Measurement Duration/Measurement Unit).

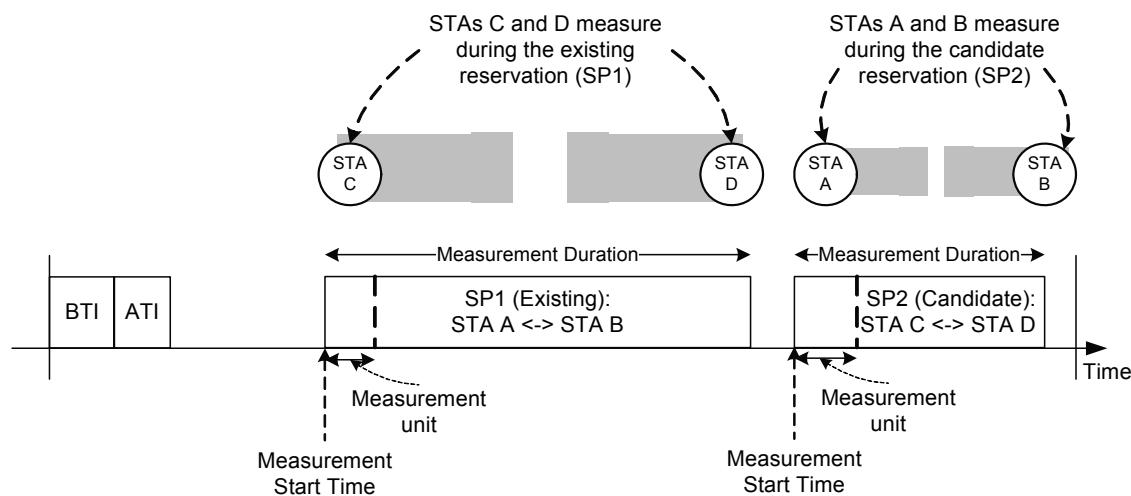

Figure 11-45—Example of spatial sharing assessment

If a non-AP and non-PCP STA receives a Directional Channel Quality request from its AP or PCP, it should perform the measurements as indicated in the request and shall report back to the AP or PCP using the Directional Channel Quality report. The report shall be formatted and transmitted as per specified in the Directional Channel Quality request. The non-AP and non-PCP STA shall set the Report Mode field (9.4.2.22) in the report frame to indicate whether it performed the measurement as requested by the AP or PCP.

11.32.3 Achieving spatial sharing and interference mitigation

An AP or PCP can estimate the channel quality across STAs participating in the BSS and implement spatial sharing and interference mitigation based on the results of the measurements performed by the STAs associated with the AP or PCP.

An AP or PCP should schedule a candidate SP that overlaps with an existing SP in its beacon interval only after it receives a Directional Channel Quality report from the STAs involved in the candidate SP.

If a candidate SP is already scheduled in the beacon interval, the AP or PCP should schedule this candidate SP time-overlapping with an existing SP in its beacon interval only after it receives a Directional Channel Quality report from the STAs involved in the existing SP.

The AP or PCP should schedule a candidate SP during a period of time in the beacon interval where the PBSS/infrastructure BSS performance is expected to be maximized. The determination of performance maximization should be based on measurement reports received by the AP or PCP, but is implementation dependent and beyond the scope of this standard.

The decision process at the AP or PCP to perform spatial sharing of a candidate and an existing SP is implementation dependent and beyond the scope of this standard.

The candidate SP is referred to as a *time-overlapped SP* following the allocation by the AP or PCP of a candidate SP overlapping in time with an existing SP.

Figure 11-46 illustrates an example of the resulting SP schedule in the beacon interval for the spatial sharing between the two SPs shown in Figure 11-45.

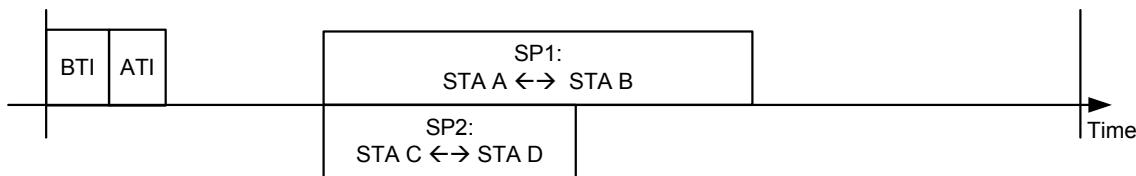

Figure 11-46—Example of spatial sharing between SP1 and SP2

The AP or PCP should periodically transmit a Directional Channel Quality request to each spatial sharing capable STA involved in a time-overlapped and existing SP scheduled under spatial sharing. In the Directional Channel Quality request that the AP or PCP transmits to each STA, the AP or PCP shall set the Target STA to the peer STA involved in the same SP and shall set the Measurement Method field to indicate RSNI.

If a spatial sharing capable non-AP and non-PCP STA receives a Directional Channel Quality request from its AP or PCP, it should perform the measurements as indicated in the request and shall report the results back to the AP or PCP using the Directional Channel Quality report. The report shall be formatted and transmitted as per specified in the corresponding Directional Channel Quality request.

The AP or PCP should stop the spatial sharing of two or more SPs if it determines that the link quality of any of the links involved in the spatial sharing has dropped below acceptable levels. This determination should be based on Directional Channel Quality reports received by the AP or PCP, but is implementation dependent and beyond the scope of this standard.

The STA may include the Traffic Scheduling Constraint Set field with the ADDTS Request frame sent to the AP or PCP for the purpose of interference mitigation. The AP or PCP should consider the information in the Traffic Scheduling Constraint Set field specified by a STA in its SP schedule.

Specific algorithms to realize spatial sharing and interference mitigation among SPs between different STAs is implementation dependent and beyond the scope of this standard.

11.32.4 PBSS and infrastructure BSS stability in OBSS scenarios

Except when performing FST (11.33), the AP or PCP limits the frequency with which it changes the operating PBSS/infrastructure BSS channel to alleviate the instability and ripple effect that might result from frequent channel changes in OBSS scenarios. Upon a channel switch, the AP or PCP of a PBSS/infrastructure BSS shall select a random number, N, uniformly distributed between [0, SwitchInterval-1] and shall not attempt a new channel switch until N beacon intervals have elapsed since the preceding channel switch. The initial value of SwitchInterval is aMinSwitchInterval and it is doubled upon every new channel switch up to a maximum value of aMaxSwitchInterval. The AP or PCP resets SwitchInterval to aMinSwitchInterval if it remains on the same operating channel for a minimum of aMaxSwitchInterval consecutive beacon intervals.

NOTE—The AP or PCP can keep the SP schedule stable across beacon intervals and minimize schedule changes. This is to allow for STAs to associate with the PBSS/infrastructure BSS or add or modify their SP reservations. Stability in the allocation schedule in a beacon interval allows a PBSS/infrastructure BSS to assess the interference pattern produced by OBSSs and adapt to the environment by scheduling SPs over periods of time in the beacon interval when less interference is expected.

11.33 Multi-band operation

11.33.1 General

A device is multi-band capable if the value of dot11MultibandImplemented is true. A multi-band capable device is said to be a member of a BSS when one or more of the STAs in the device is a member of the BSS. A STA that is part of a multi-band capable device advertises the capability by including the Multi-band element in Beacon, DMG Beacon, (Re)Association Request, (Re)Association Response, Information Request, Information Response, Probe Request, Probe Response, Announce, FST Setup Request, FST Setup Response, TDLS Discovery Request, TDLS Discovery Response, TDLS Setup Request, and TDLS Setup Response frames.

Except for the FST Setup Request and FST Setup Response frames, which shall not include more than one Multi-band element, a STA may include more than one Multi-band element in any one of these frames if it is part of a device that supports more than two bands or channels. If an AP or PCP includes one or more Multi-band elements within a (Re)Association Response frame with Status Code equal to DENIED_WITH_SUGGESTED_BAND_AND_CHANNEL or a Probe Response frame, the order in which these elements appear in the frame indicate the order, in terms of frequency band and channel number, that the device that includes the STA addressed by the frame should attempt join the BSS following the rules applicable to the respective frequency band and channel (see 11.1). For each Multi-band element contained in the frame starting from the first one and proceeding in increasing order, the STA should attempt to join the BSS using the BSSID indicated by the BSSID field, frequency band indicated by the Band ID field and channel number indicated by the Channel Number field provided the Beacon Interval and the Channel Number fields in the Multi-band element are both nonzero.

NOTE—The first Multi-band element in the frame can refer to the current operating frequency band and channel.

A multi-band capable device shall set the Band ID and Operating Class fields within a Multi-band element to specify a frequency band it supports. If the multi-band capable device is or intends to operate in the band indicated within the Multi-band element, it shall set the Channel Number field to indicate the channel of operation within that band. If the multi-band capable device is a member of a BSS both on the channel indicated in the Channel Number field within the Multi-band element and also in the channel on which this element is transmitted, then the multi-band capable device shall set the TSF Offset field within a Multi-band element to the difference between the TSF of the BSS of which the STA is member on the channel indicated in the Channel Number field of this element and the TSF of the BSS corresponding to the BSSID indicated in the Address 3 field of the MPDU in which this element is transmitted. In all other cases, the TSF Offset field shall be set to 0.

The FST session transition is managed by the FST session setup protocol. A multi-band capable device participates as an initiator or as a responder in the FST session setup. Depending on the STA's behavior during the FST session setup, the FST session can be operational in one band, or may be transferred to another band or channel in the same band, or can be operational in multiple bands and/or channels simultaneously and in this case MSDUs can be transmitted in different bands and/or channels any time an MSDU arrives at the MAC SAP. If a multi-band capable device is operational in more than one band/channel simultaneously, the STA may use the FST session setup protocol to change the operation to a single channel.

An FST session between an initiator and a responder is identified by an FSTS ID. The value of the FSTS ID is allocated by the initiator of an FST session and shall remain unchanged whether the FST session is operational in one band or more than one band simultaneously. The value of the FSTS ID shall be unique for an initiator and responder pair, and there shall be no more than one FST session between an initiator and responder pair. An initiator or responder may change the FSTS ID of its existing FST session by tearing down the existing FST session (11.33.3) and setting up a new one with a different FSTS ID value.

In each band/channel, a multi-band capable device may use the same or different MAC addresses. When the STA MAC Address Present field is equal to 1 in a Multi-band element, the STA MAC Address field in the Multi-band element specifies the MAC address that the STA uses in the band and channel that are indicated in the Multi-band element. If the STA MAC Address Present field is 0, the MAC address that the STA uses in the frequency band and channel that are indicated in the Multi-band element is the same as the address the STA uses in the current operating band and channel.

The FST session addressing mode is transparent if both initiator and responder of the FST session use the same MAC address in the frequency bands/channels involved in the FST. The FST session addressing mode is nontransparent if either the initiator or responder use different MAC addresses in the different frequency bands/channels involved in the FST session. When transparent FST is used, the STA shall present a single MAC SAP to higher layers for all frequency bands/channels in which it uses that MAC address.

An FST is allowed if the FST Setup Request and FST Setup Response frames are permitted to be transmitted as indicated in 11.3.3.

A multi-band capable device should deliver all fragments, if any, of an MSDU of an FST session before it transfers the FST session.

A multi-band capable device shall include, in any transmitted FST Setup Request frame and in any transmitted FST Setup Response frame, the Capabilities element, the Operation element, the EDCA Parameter Set element, Supported Rates and BSS Membership Selectors element, Extended Supported Rates and BSS Membership Selectors element, and Supported Channels element that are applicable to the band and channel number indicated within its most recently transmitted Multi-band element that was transmitted on the same band and channel number on which it is transmitting the FST Setup Request or FST Setup Response frames. If a Multi-band element is present in the transmitted FST Setup Request or FST Setup Response frames, the Multi-band element is considered as the most recently transmitted Multi-band element.

If a Session Transition element and a Multi-band element are present in the same frame and the values of the Operating Class and Channel Number fields within the Multi-band element are both nonzero, the value of the Band ID field related to the new band within the Session Transition element shall be the same as the Band ID field within the Multi-band element.

11.33.2 FST setup protocol

11.33.2.1 General

The FST setup protocol comprises four states and rules for how to move from one state to the next. The states are Initial, Setup Completed, Transition Done, and Transition Confirmed. In the Initial state, the FST session is operational in one or both bands/channels. In the Setup Completed state, both initiator and responder are ready to change their currently operating band(s)/channel(s). An FST session can be fully or partially transferred to another band/channel. The Transition Done state enables both initiator and responder to operate in the other band/channel if the value of the LLT was zero. Both initiator and responder have to successfully communicate in the new band/channel to reach the Transition Confirmed state. The state transition diagram of the FST setup protocol is shown in Figure 11-48.

Figure 11-47 depicts the procedure of the FST setup protocol that drives the state machine shown in Figure 11-48. The figure is an example of only the basic procedure and is not meant to be exhaustive of all possible uses of the protocol. In the figure, MLME 1 and MLME 2 represent any two MLMEs of a multi-band capable device according to the reference model described in 4.9.4. The FST Setup Request and FST Setup Response frame exchange is repeated as necessary until both the FST initiator and FST responder successfully move to the Setup Completed state, as described below. Figure 11-47 illustrates this behavior.

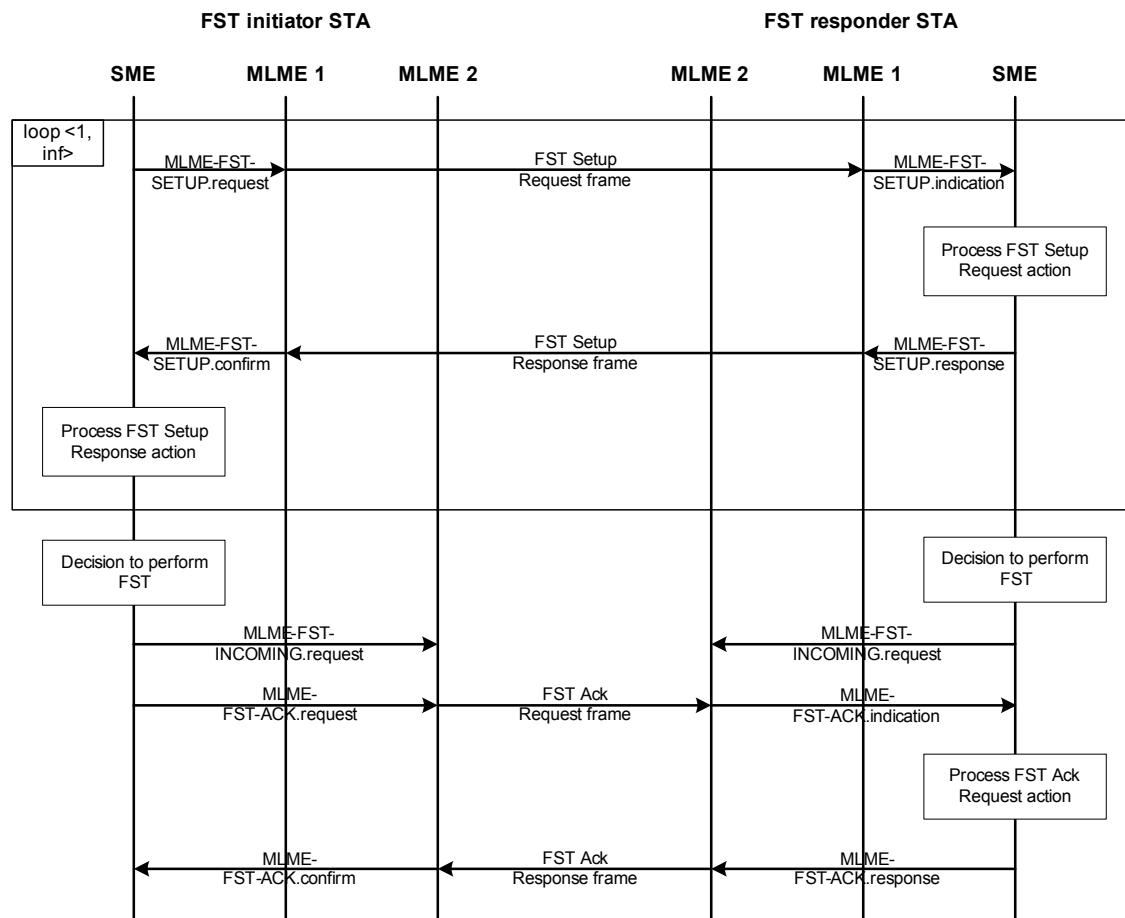

Figure 11-47—Procedure of the FST setup protocol

To establish an FST session in the Initial state and transfer it to the Setup Completed state of the FST setup protocol (Figure 11-48), an initiator and responder shall exchange FST Setup Request and FST Setup Response frames. An FST session exists in Setup Completed state, Transition Done state, or Transition Confirmed state. In the Initial and in the Setup Completed states, the old band/channel represents the frequency band/channel from which the FST session is to be transferred, and the new band/channel represents the frequency band/channel to which the FST session is to be transferred. In the Transition Done state, the new band/channel represents the frequency band/channel on which the FST Ack Request and FST Ack Response frames, if any, are transmitted, and the old band/channel represents the frequency band/channel from which the FST session is being transferred.

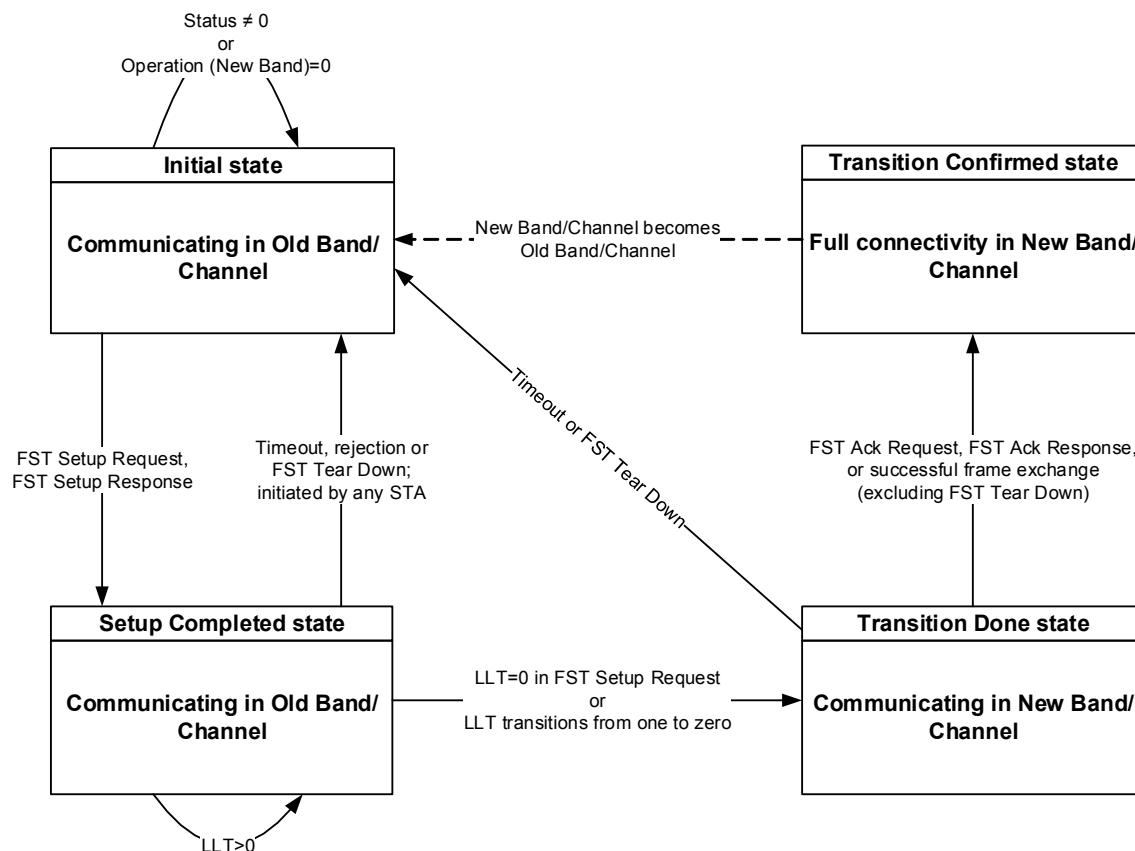

Figure 11-48—States of the FST setup protocol

The responder shall set the Status Code field to SUCCESS if it accepts the FST Setup Request, shall set the Status Code to REJECTED_WITH_SUGGESTED_CHANGES (see 9.4.1.9) to indicate that one or more parameters of the FST Setup Request frame are invalid and shall suggest alternative parameters, shall set the Status Code to PENDING_ADMITTING_FST_SESSION or PENDING_GAP_IN_BA_WINDOW to indicate that an FST setup request is pending, and shall set the Status Code field to REQUEST_DECLINED to reject an FST Setup Request frame.

A responder that is also an enabling STA (see 11.12) may set the Status Code to REJECT_DSE_BAND to indicate that the FST Setup Request frame is rejected because it was initiated by a dependent STA (see 11.12) that is requesting transition to a frequency band subject to DSE procedures. In this case, if the responder is the enabling STA for the dependent STA, the responder may include a Timeout Interval element in the FST Setup Response frame to indicate the period in TUs before which it initiates an FST Setup with the dependent STA. The Timeout Interval Type field within the Timeout Interval element shall

be set to 4. The responder can use the parameters in the FST Setup Request frame received from the dependent STA to initiate an FST Setup with the initiator.

A responder that is also a dependent STA and not enabled shall reject all received FST Setup Request frames for transitioning to a frequency band subject to DSE procedures, except if the transmitter of the FST Setup Request frame is the enabling STA of the dependent STA.

11.33.2.2 Transitioning between states

A state transition within the FST setup protocol is controlled by the State Transition Timer (STT). Each STA maintains an STT for each FST session. A STA shall move to the Initial state when the STT moves from 1 to 0 (other than set to 0) or upon reception or transmission of an FST Teardown frame.

The initiator shall set the STT to the value of the FSTSessionTimeout field at successful transmission of an FST Setup Request frame and at each Ack frame sent in response to a received FST Setup Response frame with the Status Code field equal to PENDING ADMITTING_FST_SESSION or PENDING_GAP_IN_BA_WINDOW. The initiator shall set the STT to 0 at the transmission of an Ack frame sent in response to a received FST Setup Response frame with the value of the Status Code field equal to SUCCESS.

The responder shall set the STT to the value of the FSTSessionTimeout field at successful transmission of an FST Setup Response frame. The responder shall set the STT to 0 at each transmission of an Ack frame sent in response to the reception of an FST Setup Request. The responder should send an FST Setup Response frame no later than FSTSessionTimeout after the transmission of an Ack frame sent in response to a received FST Setup Request frame or successful transmission of an FST Setup Response frame with the status code field equal to PENDING ADMITTING_FST_SESSION or PENDING_GAP_IN_BA_WINDOW. In the latter case, the responder shall transmit the unsolicited FST Setup Response frame to the initiator.

There might be multiple FST Setup Request and FST Setup Response frame transmissions by the initiator and the responder, respectively, until the FST session between these STAs becomes established. At each transition, or attempt to transition, from the Initial state to the Setup Completed state, the initiator and responder shall perform the following procedure:

- a) The initiator sends an FST Setup Request frame to the responder.
- b) Upon receipt of an FST Setup Request frame, the responder shall respond with an FST Setup Response frame unless it has a pending FST Setup Request frame addressed to the initiator and the responder has a numerically larger MAC address (see 12.7.1.1 for comparison of MAC addresses) than the initiator's MAC address, in which case, the responder shall ignore the received FST Setup Request.
- c) If, after the reception of the acknowledgment to the initiator's FST Setup Request frame, the initiator receives an FST Setup Request frame from the responder, the initiator shall not respond with an FST Setup Response frame if its MAC address is numerically larger (see 12.7.1.1 for comparison of MAC addresses and see 11.1.4.3.6) than the responder's MAC address. Otherwise, if its MAC address is numerically smaller than the responder's MAC address, it becomes the responder and shall respond with an FST Setup Response frame and shall not send the FST Setup Request frame during the current FST session transition.
- d) The initiator shall not move to the Setup Completed state if at least one of the following conditions is met:
 - 1) The initiator does not successfully receive an FST Setup Response frame from the responder within the STT.
 - 2) The value of the Status Code field in the received FST Setup Response frame from the responder is different from SUCCESS.
 - 3) A state-specific exception in Table 11-20 takes place.

- e) The initiator shall move to the Setup Completed state if none of conditions d(1), d(2), and d(3) is met.
- f) The responder shall not move to the Setup Completed state if at least one of the following conditions is met:
 - 1) The responder does not receive the acknowledgment to its transmitted FST Setup Response frame
 - 2) The value of the Status Code field in the FST Setup Response frame it transmitted to the initiator was different from SUCCESS
 - 3) The value of the Setup and Operation subfields within the Session Transition element in the transmitted FST Setup Response frame results in a status different from any of the rows shown in Figure 11-21, in which case the responder shall set the Status Code field with the transmitted FST Setup Response frame to REQUEST_DECLINED.
 - 4) The resulting status of the Operation subfield in the New Band field is 0.
- g) The responder shall move to the Setup Completed state if none of conditions f(1), f(2), f(3) and f(4) is met.

Table 11-20—Exceptions for the initiator

| State | Condition | Meaning | Next state |
|--------------|---|---|-------------------|
| Initial | FST Setup Response frame with Status Code PENDING ADMITTING_F ST_SESSION | Pending, responder in process of admitting FST session. | Initial |
| Initial | FST Setup Response frame with Status Code PENDING_GAP_IN_BA_WI NDOW | Pending, block ack window at the responder has gaps. | Initial |
| Initial | FST Setup Response frame with Status Code REJECTED_WITH_SUGGE STED_CHANGES | One or more parameters of the FST Setup Request frame is invalid and the responder suggests alternative parameters. | Initial |
| Initial | FST Setup Response frame with Status Code REQUEST_DECLINED | Responder rejects the request. One particular case is that values of the operating class and channel number fields within the Multi-band element, if any, received in the FST Setup Request frame is different from the value of the corresponding fields within the Multi-band element, if any, transmitted in the following FST Setup Response. | Initial |
| Initial | FST Setup Response frame with Status Code REJECT_DSE_BAND | Responder rejects the request since the initiator is a dependent STA and the request is for transitioning to a frequency band subject to DSE procedures. In the rejection, the responder can include a Timeout Interval element. | Initial |
| Initial | Resulting status is different from shown in Table 11-21 | The responder is not able to complete the setup. | Initial |
| Initial | Resulting status of the Operation field in the New Band field is 0 in Table 11-21 | The operation in the new band is disabled. | Initial |

Table 11-20—Exceptions for the initiator (continued)

| State | Condition | Meaning | Next state |
|-----------------|--|---|-----------------|
| Setup Completed | FST Setup Response frame with Status Code SUCCESS and value of the LLT field within the FST Setup Request frame is greater than zero | The STA is ready to switch to the new band if the link is lost in the old band. | Setup Completed |
| Setup Completed | Transmission or reception of FST Teardown frame | Termination of FST session. | Initial |

If, upon transition to the Setup Completed state, the value of the LLT field within the last successful FST Setup Request frame received by the responder or transmitted by the initiator was equal to 0, the initiator and responder shall immediately move to the Transition Done state.

If, upon transition to the Setup Completed state, the value of the LLT field within the last successful FST Setup Request frame received by the responder or transmitted by the initiator was greater than 0, the initiator and responder shall proceed as follows:

- If the last FST Setup Request or FST Setup Response frames exchanged between the initiator and responder included a Switching Stream element, then all of the streams within the Switching Stream element that have the LLT Type field set to 1 shall be switched using the Stream-based Link Loss Countdown, and all of the streams within the Switching Stream element that have the LLT Type field set to 0 shall be switched using the STA-based Link Loss Countdown.
- If neither the FST Setup Request nor the FST Setup Response frames exchanged between the initiator and responder included a Switching Stream element, then the streams shall be switched using the STA-based Link Loss Countdown.

The FST transition for the STA, if STA-based, or the stream, if stream-based, from the Setup Completed state to the Transition Done state shall occur immediately after the corresponding Link Loss countdown timer transitions from 1 to 0 within any of the initiator or responder of the FST session.

An initiator and responder shall perform the STA-based and stream-based Link Loss Countdown as follows:

- STA-based Link Loss Countdown: Both initiator and responder shall remain in the Setup Completed state and start a Link Loss countdown timer with an initial value of $LLT \times 32 \mu s$. The Link Loss countdown is reloaded with the value of $LLT \times 32 \mu s$ every time that an individually addressed frame is received from the peer STA of the FST session.
- Stream-based Link Loss Countdown: Both the initiator and responder shall start a Link Loss countdown timer with an initial value of $LLT \times 32 \mu s$ for each stream identified within the Switching Stream element. The Link Loss countdown for a stream is reloaded with the value of $LLT \times 32 \mu s$ every time that an individually addressed frame for that stream is received from the peer STA of the FST session.

Before leaving the Setup Completed state, an initiator and/or responder that is performing a full FST may transmit an FST Setup Response frame in the old band/channel with the Status Code field set to PERFORMING_FST_NOW and with the RA field set to the broadcast address to notify other STAs in the BSS of the STA's forthcoming full FST.

Table 11-21 shows the FST session status at each state transition. The Setup and Operation subfields shown in Table 11-21 are present within the Session Transition element. When the value of a subfield in the FST Setup Request frame is different from the value of that same subfield in the following FST Setup Response

frame, the resulting status shall be the logical AND of the value of the corresponding subfields in both the FST Setup Request and the FST Setup Response frames.

Table 11-21—FST status at state transition

| From State | Old band resulting status | | New band resulting status | | To State | Definition |
|-----------------|---------------------------|-----------|---------------------------|-----------|----------------------|--|
| | Setup | Operation | Setup | Operation | | |
| Initial | 1 | 1 | 0 | 0 | Initial | New band setup and operation are disabled. |
| Initial | 1 | 1 | 1 | 0 | Initial | New band operation is disabled, the setup is kept alive. |
| Initial | 0 | 0 | 1 ^a | 1 | Setup Completed | FST session is operational in new band. |
| Initial | 1 ^a | 1 | 1 ^a | 1 | Setup Completed | FST session is operational in both bands. |
| Initial | 1 | 0 | 1 ^a | 1 | Setup Completed | FST session is operational in new band; FST session in old band is kept alive. |
| Setup Completed | Unchanged | Unchanged | Unchanged | Unchanged | Transition Done | No status changes. |
| Transition Done | Unchanged | Unchanged | Unchanged | Unchanged | Transition Confirmed | No status changes. |

^a The value of this field remains unchanged during the FST session transition.

Upon transition to the Transition Done state and if transparent FST is used, the association state (see 11.3.1) of the STA corresponding to the old band/channel is transferred to the STA corresponding to the new band/channel.

To transition from the Transition Done state to the Transition Confirmed state, the initiator and responder shall perform the following procedure within the channel number of the operating class and band ID specified in the Multi-band element negotiated during the FST session setup:

- a) The State transition is controlled by the State Transition Timer (STT). Each STA of the FST session has its own STT. The initiator shall transition to the Initial state when its STT transitions from 1 to 0, but not when the STT is set to 0. The responder shall transition to the Initial state when its STT transitions from 1 to 0, but not when the STT is set to 0.

The initiator shall set the STT to the value of the FSTSessionTimeout field at successful transmission of an FST Ack Request frame or at transmission of any individually addressed MPDU to the responder. The initiator shall set the STT to 0 at the transmission of an Ack frame sent in response to a received FST Ack Response from the responder or at reception of an Ack frame received in response to a frame sent to the responder.

The responder shall set the STT to FSTSessionTimeout at transmission of an FST Ack Response frame or at transmission of any other individually addressed MPDU to the initiator. The responder shall set the STT to 0 at the reception of an Ack frame received in response to a transmitted FST Ack

Response frame or at the reception of any individually addressed frame sent by the initiator. The responder shall transmit an FST Ack Response frame to the initiator no later than FSTSessionTimeout after the transmission of an Ack frame sent in response to a received FST Ack Request from the initiator.

- b) The SME of both the initiator and responder generates an MLME-FST-INCOMING.request primitive that includes the parameters of the FST. This primitive shall be generated to the MLME associated with the channel number, operating class, and band ID specified in the Multi-band element negotiated during the FST session setup. This primitive notifies the MLME of an impending FST.
- c) The initiator shall send an FST Ack Request frame or may send any other individually addressed MPDU to the responder.

NOTE—Depending on the BSS configuration in the new band/channel, the initiator might have to associate and/or authenticate with the BSS before it is allowed to transmit a frame to the responder.

- d) Upon receipt of an FST Ack Request frame, the responder shall respond to the initiator with an FST Ack Response frame.

NOTE—Depending on the BSS configuration in the new band/channel, the responder might have to associate and/or authenticate with the BSS before it is allowed to transmit a frame to the initiator.

- e) The initiator shall move to the Transition Confirmed state
 - 1) Upon transmission of an Ack frame sent in response to any individually addressed frame, including an FST Ack Response frame, received from the responder; or
 - 2) When the initiator receives an Ack frame from the responder to any non-FST Ack Request frame the initiator transmitted to the responder.
- f) The responder shall move to the Transition Confirmed state
 - 1) When the responder receives an Ack frame in response to any individually addressed frame, including an FST Ack Response frame, sent to the initiator; or
 - 2) Upon transmission of an Ack frame sent in response to any individually addressed non-FST Ack Request frame.

Following the transition to the Transition Confirmed state, a STA shall adopt the role indicated in the STA Role field corresponding to the channel number, operating class and band ID that was last transmitted to the peer STA within the Multi-band element. If the STA was operating within a PBSS, was the initiator of the FST session, and the new role of the STA is as an IBSS STA, then the STA shall be a DFS Owner of the IBSS.

In case the transition to the Transition Confirmed state was the result of a Stream-based Link Loss Countdown, the stream shall remain in the Transition Confirmed state until all of the streams included within the corresponding Switching Stream element reach the Transition Confirmed state. Once all streams within the corresponding Switching Stream element reach the Transition Confirmed state or the FST session ceases to exist, the STA moves to the Initial state.

If neither the initiator nor the responder perform in the role of AP or PCP as indicated through the STA Role field within the Multi-band element corresponding to the new band for that STA, one of the STAs can initialize a new BSS (11.1) on the new band for communication between the STAs.

If the value of the Switch intent field in the last Session Transition element transmitted to a responder is 1, an initiator may switch to the new band and channel indicated in the last transmitted FST Setup Request frame and Multi-band element, respectively, if at least one of the following conditions is satisfied:

- The value of the Status Code field within the FST Setup Response frame received in response to the transmitted FST Setup Request frame is equal to REQUEST_DECLINED.

- The initiator moves to the Initial state due to the STT at the initiator moving from 1 to 0.
- The initiator moves to the Initial state due to the reception of an FST Teardown frame from the responder.

Immediately before an initiator switches to a new band and/or channel, the initiator shall disassociate and delete all TS and block ack agreement(s) it has with a responder for which at least one of the above conditions is met.

Following the successful FST transition to a new band, the STA of the FST session shall follow the medium access rules applicable to the new band.

11.33.2.3 FST TS switching

If a STA transmitting an FST Setup Request frame or an FST Setup Response frame does not intend to switch all its streams, then the STA shall include the Switching Stream element in the transmitted frame to indicate which streams are requested to be transferred to the other band/channel. If the FST Setup Request frame includes a Switching Stream element, the FST Setup Response frame should include a Switching Stream element. If the FST Setup Request frame does not include a Switching Stream element, the FST Setup Response frame may include a Switching Stream element. If the STA transmitting the Switching Stream element has not set up a stream in the band indicated in the New Band ID field within this element, it shall set the Stream ID In New Band Valid field to 0. A STA may set up a stream in any band/channel by transmitting ADDBA Request or ADDTS Request frames that include the Multi-band element.

If a STA transmits an ADDTS Request frame to another STA with which it has established an FST session and the ADDTS Request frame is transmitted in a band or channel different from the band or channel to which the ADDTS request is intended to apply, the ADDTS Request frame shall include the Multi-band element with the Band ID, Operating Class, and Channel Number fields set to indicate to which channel the ADDTS Request frame applies. In addition, if these STAs use the nontransparent mode for FST, the STA transmitting the ADDTS Request frame sets the STA MAC Address Present field to 1 and the STA MAC Address field to the MAC address that the STA uses in the band and channel number that are indicated in the Multi-band element contained in the ADDTS Request frame. Similar to the ADDTS Request frame, the Multi-band element shall be included in the ADDBA Request, ADDTS Response, ADDBA Response, DELTS, and DELBA frames when these frames are transmitted in a band or channel different from the band or channel to which they are intended to apply.

When using transparent mode to transfer an FST session corresponding to a TID/TSID, the Direction subfield within the TSPEC element, if any, used to set up the TID/TSID should not be set to indicate a bidirectional link. This enables the SME to use the TID/TSID in conjunction with the source and destination MAC addresses in both the old and new frequency band/channel to uniquely identify the FST session.

If any of the ADDTS variants is used to switch the TS, then the PTP TSPEC or the DMG TSPEC shall be used when the TS is being established to operate in a DMG BSS, and the Basic TSPEC shall be used when the TS is being established to operate in a non-DMG BSS irrespective of the band and channel used to communicate the ADDTS frames and the DMG ADDTS frames.

The rules defined below apply when the ADDTS frames or the DMG ADDTS frames are used to switch TS. When the ADDTS frames and the DMG ADDTS frames are used, then the ADDTS requester and the ADDTS responder provide the functions defined for the ADDBA originator and the ADDBA recipient, respectively.

If the ADDBA recipient includes the Switching Stream element in any of the FST Setup Request or FST Setup Response frames and if the Stream ID In New Band Valid field within the Switching Stream element is 0, the ADDBA originator should issue the DELBA frame to reject the BlockAck agreements indicated in

the Stream ID In Old Band field. If the originator intends to establish new BlockAck agreements in the band indicated in the Multi-band element sent by the recipient and with the recipient MAC address indicated in the Multi-band element sent by the recipient, the originator shall transmit an ADDBA Request frame addressed to the recipient.

The originator may include the Multi-band element and the Ethernet type TCLAS element in the ADDBA Request frame. If the MAC Addresses of the originator and recipient to be used in the new band are different from the MAC addresses used in the old band, then the ADDBA Request frame sent in the old band to establish a block ack agreement in the new band shall include the Multi-band and the TCLAS elements. The resulting block ack agreement, if established, applies to the band and channel identified in the Multi-band element included in the ADDBA Request frame. The BlockAck is identified by the TID/TSID and MAC addresses of the originator and the recipient used in the band and channel indicated in the Multi-band element included in ADDBA Request and ADDBA Response frames.

The ADDBA Request frame may be issued in the old band and channel, and the corresponding ADDBA Response frame may be transmitted in the band and channel indicated in the Multi-band element within the ADDBA Request frame.

The following rules for establishment of a multi-band block ack agreement shall apply:

- a) If the TA and/or the RA fields of the ADDBA Request frame are different from the originator MAC address and/or the recipient MAC address, respectively, used in the channel and band where the block ack agreement should operate, then the originator shall set the Source Address field and the Destination Address field of the classifier to the originator MAC address and the recipient MAC address, respectively, to be used in the band and channel indicated in the Multi-band element included in the ADDBA Request frame.
- b) If the TA and RA are equal to the originator MAC address and the recipient MAC address, respectively, then the Multi-band element, if any, included in the ADDBA Request frame shall indicate the band and channel over which the established block ack agreement is operating. The TCLAS element shall not be included in this ADDBA Request frame.
- c) The Multi-band element should not be included in the ADDBA Request frame if in the case b) the ADDBA Request frame is issued in the same band and channel over which the block ack agreement shall operate.
- d) If the TA and/or the RA fields of the ADDBA Response frame are different from the recipient MAC address and/or the originator MAC address, respectively, to be used in the channel and band where the block ack agreement should operate, then the recipient shall set the Source Address field and the Destination Address field of the classifier to the recipient MAC Address and the originator MAC address, respectively, to be used in the band and channel indicated in the Multi-band element included in the ADDBA Response frame. The indicated band and channel shall be equal to the band and channel indicated in the Multi-band element of the ADDBA Request frame.
- e) If the TA and RA fields are equal to the recipient MAC address and the originator MAC address, respectively, then the Multi-band element, if any, included in the ADDBA Response frame shall indicate the band and channel over which the established block ack agreement is operating. The indicated band and channel shall be equal to the band and channel indicated in the Multi-band element of the ADDBA Request frame. The TCLAS element shall not be included in the ADDBA Response frame.
- f) The Multi-band element should not be included in the ADDBA Response frame if in case e) the ADDBA Response frame is issued in the same band and channel over which the block ack agreement, if established, shall operate.

11.33.3 FST teardown

At the Setup Completed state or Transition Done state, a STA may transmit an FST Teardown frame to its peer STA of the FST session in order to tear down an FST session that was previously set up using the FST Setup Request/Response frame exchange. Upon transmission or reception of an FST Teardown frame, the initiator and responder move to the Initial state (11.33.2). When moving to the Initial state and if the value of the Switch intent field in the last Session Transition element transmitted to a responder is 1, the initiator behaves as described in 11.33.2.2.

11.33.4 On-channel Tunneling (OCT) operation

OCT allows a STA of a multi-band capable device to transmit an MMPDU that was constructed by a different STA of the same device. An MMPDU transmitted this way is referred to as an *OCT MMPDU*. The MLME of the nontransmitting STA that constructs or is the destination of an OCT MMPDU is referred to as an *NT-MLME*. The MLME of the STA that transmits or receives an OCT MMPDU over the air is referred to as a *TR-MLME*.

NOTE—OCT can be used in conjunction with or independent from the FST setup protocol.

Figure 11-49 depicts the overall OCT procedure. In this figure, <primitive> refers to the name of any of the MLME primitives defined in 6.3 that meets all of the following conditions:

- Defines request, indication, response, and confirm primitives, or just request and indication primitives.
- Includes a peer Multi-band element. The peer Multi-band element is used to identify the peer NT-MLME.
- Includes a local Multi-band element. The local Multi-band element is used to identify the local NT-MLME.

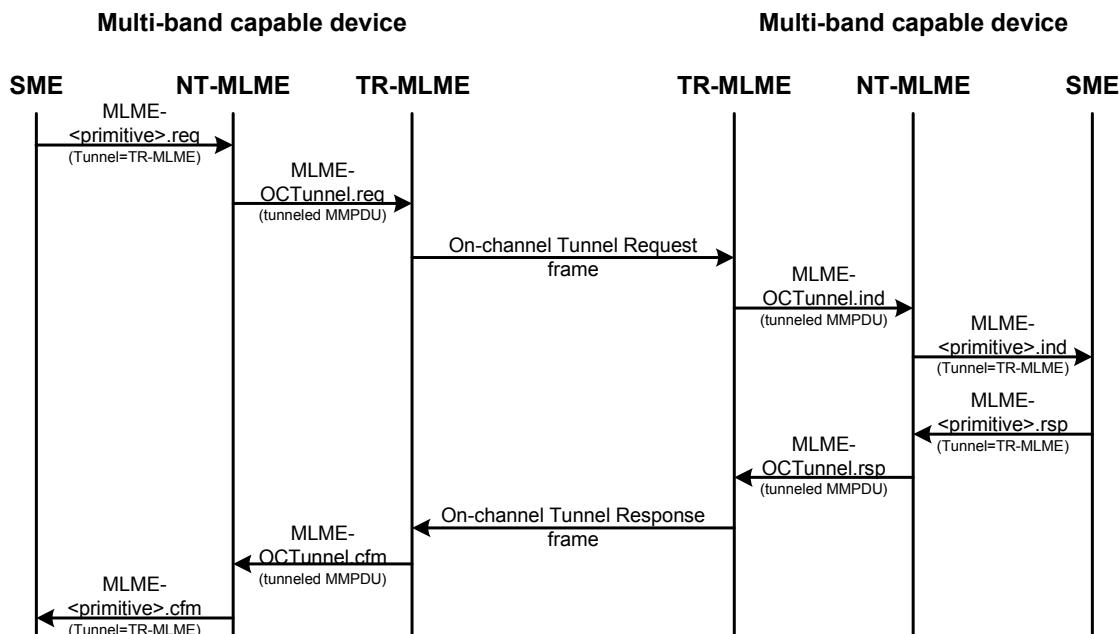

Figure 11-49—On-channel tunneling procedure

An MLME primitive meeting all of the above conditions is referred to as an *OCT MLME primitive*.

NOTE—MLME-AUTHENTICATE, MLME-ASSOCIATE, and MLME-REASSOCIATE are examples of primitives that are OCT MLME primitives.

To transmit a tunneled MMPDU, the SME of a multi-band capable device generates an OCT MLME request primitive that includes the peer Multi-band element and the local Multi-band element.

A NT-MLME receiving an OCT MLME request primitive shall

- As defined in this standard, process the request and construct an OCT MMPDU corresponding to the primitive in question. The NT-MLME shall not transmit any frame as a result of this primitive.
- Generate an MLME-OCTunnel.request primitive with parameters including the OCT MMPDU and the peer Multi-band element. The MLME-OCTunnel.request primitive shall be generated to the TR-MLME identified by the local Multi-band element which is contained within the OCT MMPDU.

A TR-MLME receiving an MLME-OCTunnel.request primitive shall transmit an On-channel Tunnel Request frame addressed to the peer TR-MLME and which includes the tunneled MMPDU.

A TR-MLME receiving an On-channel Tunnel Request frame shall generate an MLME-OCTunnel.indication primitive. The MLME-OCTunnel.indication primitive shall be generated to the NT-MLME identified by the peer Multi-band element contained within the received On-channel Tunnel Request frame.

A NT-MLME receiving an MLME-OCTunnel.indication primitive shall

- As defined in this standard, process the OCT MMPDU parameter of the primitive as if the MMPDU had been received over the air.
- Generate an OCT MLME indication primitive corresponding to the frame type of tunneled MMPDU. This primitive is generated to the SME of the STA, which processes the MMPDU as defined in this standard.

In the case of a .request/.indication primitive, the process stops here. Otherwise, the process continues as described below.

The peer SME responds to the reception of an OCT MLME indication primitive by generating the corresponding OCT MLME response primitive. This response includes the peer Multi-band element and the local Multi-band element.

A NT-MLME receiving an OCT MLME response primitive shall

- As defined in this standard, process the response and construct an OCT MMPDU corresponding to the primitive in question. The NT-MLME shall not transmit any frame as a result of this primitive.
- Generate an MLME-OCTunnel.request primitive with parameters including the OCT MMPDU and the peer Multi-band element. The MLME-OCTunnel.request primitive shall be generated to the TR-MLME identified by the local Multi-band element which is contained within the OCT MMPDU.

A TR-MLME receiving an MLME-OCTunnel.request primitive transmits an On-channel Tunnel Request frame addressed to the peer TR-MLME that includes the tunneled MMPDU.

A TR-MLME receiving an On-channel Tunnel Request frame generates an MLME-OCTunnel.indication primitive. The MLME-OCTunnel.indication primitive is generated to the NT-MLME identified by the peer Multi-band element contained within the received On-channel Tunnel Request frame.

A NT-MLME receiving an MLME-OCTunnel.indication primitive

- Processes the OCT MMPDU parameter of the primitive as if the MMPDU had been received over the air.
- Generates an OCT MLME confirm primitive corresponding to the frame type of the OCT MMPDU. This primitive is directed at the SME.

11.33.5 FST payload

When FST action frames are forwarded by an AP, FST uses Ethertype 89-0d frames as defined in Annex H. In this case, the FST payload contains an FST Action frame body as is specified in 9.6.21.

11.34 MMSL cluster operation

11.34.1 Introduction

A STA is MMSL cluster capable if it includes an MMS element in its most recent transmission of (Re)Association Request, (Re)Association Response, ADDTS Request, ADDTS Response, Probe Request, Probe Response, Information Request, or Information Response frames.

An MM-SME coordinated STA shall be MMSL cluster capable, except for an MM-SME that coordinates two STAs where one STA is a member AP or member PCP in a centralized AP or PCP cluster and the other STA is associated to the S-AP of the centralized AP or PCP cluster.

NOTE—In the centralized clustering case, the two STAs in the MM-SME are communicating with different MAC entities with different SMEs, so there is no individual link for MMSL.

A non-MM-SME coordinated STA may be MMSL cluster capable.

An MMSL cluster capable STA shall include an MMS element in transmitted (Re)Association Request and (Re)Association Response frames.

As described in 4.9.3, an MM-SME may coordinate multiple MACs (and their respective STAs).

Each STA coordinated by the same MM-SME may be used for the MMSL cluster setup and maintenance.

The PCP may deliver an MMS element that includes a MAC address that is equal to the BSSID and other MAC addresses that are not equal to the BSSID. The MAC addresses that are not the BSSID shall not be used to request and respond to association, reassociation, probing, and scheduling services provided by the PCP.

If a non-AP and non-PCP STA has delivered an MMS element to the AP or PCP, the non-AP and non-PCP STA shall not send an ADDTS Request frame to the AP or PCP with the TA field equal to a MAC address that was not included in the delivered MMS element.

If an MM-SME coordinated STA is associated with an AP or PCP that allocates one single AID to all STAs advertised in the MMS element sent by the MM-SME coordinated STA, the AID can be also used to identify the MMSL cluster. If the AID is provided for one of the advertised STAs of the MM-SME coordinated STA, then the same AID applies to all STAs whose addresses are referenced in the delivered MMS element and the Single AID field is set as per Table 9-247.

Table 11-22 covers the possible cases of the AID use for MMSL cluster identification.

Table 11-22—Setting of Single AID field

| MMSL cluster configuration | Is the Single AID allocated to the MM-SME coordinated STA A? | Is the Single AID allocated to the MM-SME coordinated STA B? | AID identification of MMSL cluster |
|---|--|--|------------------------------------|
| Non-AP and non-PCP MM-SME coordinated STA A is associated to PCP MM-SME coordinated STA B. | Yes | Yes | Yes |
| Non-AP and non-PCP MM-SME coordinated STA A and non-AP and non-PCP MM-SME coordinated STA B are both associated to the same BSS. | Yes | Yes | Yes |
| Non-AP and non-PCP MM-SME coordinated STA A is associated to a BSS and non-AP and non-PCP MM-SME coordinated STA B is not associated to the BSS. | Yes | No | No |
| Non-AP and non-PCP MM-SME coordinated STA A and non-AP and non-PCP STA B are both associated to the same BSS. | Yes | NA | Yes |
| Non-AP and non-PCP MM-SME coordinated STA A is associated to a BSS and one MAC entity of non-AP and non-PCP MM-SME coordinated STA B is associated to the same BSS. | Yes | NA | Yes |

11.34.2 MMSL cluster setup

11.34.2.1 General

To establish an MMSL cluster, an MMS element of an MM-SME coordinated STA that lists its advertised STAs shall be delivered to the peer STA. The peer STA may be an MM-SME coordinated STA or a non-MM-SME coordinated STA. An MMSL cluster is identified by one of the following:

- a) Advertised MAC addresses of the MAC entities of two MM-SME coordinated STAs
- b) Advertised MAC addresses of the MAC entities of an MM-SME coordinated STA and of a non-MM-SME coordinated STA

In both cases, the MMS element shall be exchanged between the STAs to set up the MMSL cluster agreement.

If an MMSL cluster capable non-MM-SME coordinated STA receives an ADDTS Request frame that includes an MMS element, the SME of the non-MM-SME coordinated STA shall include the received MMS element in the MLME-ADDTs.response primitive used to send the ADDTS Response frame if the SME accepts the MMSL cluster setup. The SME of the non-MM-SME coordinated STA may set the MMS Element Owner field to “no Owner” in the MMS element included in an MLME-ASSOCIATE.request primitive and MLME-ADDTs.request primitive to establish the MMSL cluster with an MM-SME coordinated STA.

The MMS element shall be exchanged between the STAs of the MMSL cluster only once per MMSL cluster setup.

11.34.2.2 MMSL cluster setup of non-AP and non-PCP MM-SME coordinated STA with AP or PCP

The Association Request and Response frames are used to establish an MMSL cluster between a non-AP and non-PCP MM-SME coordinated STA and an AP or PCP. If the AP or PCP is not an MM-SME coordinated STA, the AP or PCP shall include the MMS element received from the non-AP and non-PCP MM-SME coordinated STA in the Association Response frame sent as response. If the AP or PCP is an MM-SME coordinated STA, the AP or PCP should include its own MMS element that contains its advertised MAC entities in the Association Response frame and shall not include the MMS element received from the non-AP and non-PCP MM-SME coordinated STA in the Association Response frame. The AP or PCP shall not respond with any MMS element if it is not MMSL cluster capable.

The setup of the MMSL cluster fails if the Association Response frame does not contain the MMS element.

11.34.2.3 MMSL cluster setup of non-AP and non-PCP STA with another non-AP and non-PCP STA

If a non-AP and non-PCP MM-SME coordinated STA associated with an AP or PCP has established an AID identified MMSL cluster with the AP or PCP, the non-AP and non-PCP MM-SME coordinated STA shall not use a MAC address that was not included in the MMS element delivered to the AP or PCP to establish an MMSL cluster with another non-AP and non-PCP MM-SME coordinated STA associated with the same AP or PCP.

An ADDTS Request/Response frame exchange with a PTP TSPEC shall be used to establish the MMSL cluster between non-AP and non-PCP MM-SME coordinated STAs and between a non-AP and non-PCP MM-SME coordinated STA and a non-AP and non-PCP non-MM-SME coordinated STA.

A non-AP and non-PCP MM-SME coordinated STA shall include an MMS element that contains its advertised MAC entities in transmitted ADDTS Request frames. If the non-AP and non-PCP STA is not an MM-SME coordinated STA, the non-AP and non-PCP STA should include the MMS element with the MMS Element Owner field set to “no Owner” in the ADDTS Request frame.

The non-AP and non-PCP MM-SME coordinated STA shall include its own MMS element that contains its advertised MAC entities in transmitted ADDTS Response frames. The non-MM-SME coordinated STA may include the MMS element of the MM-SME coordinated STA from which it received an ADDTS Request frame in the ADDTS Response frame sent as response. The non-MM-SME coordinated STA shall not respond with any MMS element if it is not MMSL cluster capable.

The setup of the MMSL cluster fails if the ADDTS Response frame does not contain the MMS element.

11.35 DMG coexistence with non-IEEE-802.11 systems

This subclause describes the features available in this standard to improve coexistence with other DMG systems, including IEEE Std 802.15.3cTM.

The same common channelization that is defined in other DMG standards and specifications is adopted (20.3.1). In regulatory domains where 2 or more channels are defined, a DMG STA should support at least 2 channels.

An AP should not start an infrastructure BSS on a channel where the signal level is at or above aDMGDetectionThres or upon detecting a valid IEEE 802.15.3cTM CMS preamble at a receive level greater than or equal to -60 dBm.

If a DMG STA is capable of performing directional channel measurements (11.32) to detect non-IEEE-Std-802.11 transmissions on a channel, it can report the results of the measurements to the STA's AP or PCP.

If a DMG STA detects a non-IEEE-802.11 transmission on its channel or if the AP or PCP receives a report (11.11) from a DMG STA on a non-IEEE-802.11 transmission, the following mechanisms might be used to mitigate interference:

- Change operating channel (11.9)
- Beamforming (10.38)
- Reduce transmit power (11.8)
- Perform FST (11.33)
- Move the TBTT (11.31.2), and thus the beacon interval, in the case of an AP or PCP
- Change the schedule of SPs and CBAPs in the beacon interval (9.4.2.132) in the case of an AP or PCP
- Defer transmission for a later time
- For periods of time in the beacon interval where the STA experiences poor channel quality, the STA can use the Traffic Scheduling Constraint Set field within the DMG TSPEC element (9.4.2.134) to request its AP or PCP to avoid scheduling an SP for that DMG STA during those periods of time in the beacon interval.

11.36 DMG relay procedures

11.36.1 General

Relaying allows a source relay endpoint DMG STA (REDS) to transmit frames to a destination REDS with the assistance of another DMG STA called the *relay DMG STA (RDS)*. Relaying can improve the reliability of communication in a DMG BSS in case the direct link between the source REDS and the destination REDS is disrupted.

A STA is a REDS if both dot11REDSActivated and dot11RelayActivated are true. A REDS shall set the Relay Client field within its Relay Capabilities element to 1. A STA is an RDS if both dot11RDSActivated and dot11RelayActivated are true. An RDS shall set the Relay Supporter field within its Relay Capabilities element to 1. A STA is relay capable if dot11RelayActivated is true and it is either a REDS or an RDS or both, and it is relay incapable otherwise.

A relay capable STA shall advertise its capability by including the Relay Capabilities element in (Re)Association Request, (Re)Association Response, Probe Request, Probe Response, Information Request, and Information Response frames. An AP or relay capable PCP may include the Relay Capabilities element in DMG Beacon frames.

For a STA to operate as a REDS or an RDS in an Infrastructure BSS or PBSS, the following conditions shall be met:

- The STA is a member of the Infrastructure BSS or PBSS.
- The TDDTI field within the DMG STA Capabilities element of the AP or PCP of the BSS is 1.
- The Relay permission field within the Relay Capabilities element of the AP or PCP of the BSS is 1.

A source REDS, a destination REDS and an RDS can establish the types of relay operation as specified in 10.40.

As needed, in the following subclauses, source REDS, RDS, and destination REDS are expressed as ‘S’, ‘R’, and ‘D’, respectively. Also, a direct link between STA S and STA D can be simply referred to as *S-D link*.

11.36.2 Common relay setup procedures

11.36.2.1 Introduction

This subclause describes the procedures that a source REDS, a destination REDS, and an RDS employ to set up a relay operation among these STAs. These procedures are used for both link switching and link cooperation relays, and shall be performed in the order shown in this subclause.

11.36.2.2 Relay capabilities and RDS discovery procedures

A source REDS can obtain the capabilities of other STAs in the BSS following the STA’s association with the BSS or with the transmission of an Information Request frame as described in 11.30.1.

A source DMG STA that intends to set up relay operation with a destination DMG STA shall obtain the capabilities of the destination DMG STA prior to initiating the relay setup procedure with the destination DMG STA. The source DMG STA may attempt to set up relay operation with the destination DMG STA only if both the source DMG STA and destination DMG STA are REDS, and there exists at least one RDS in the BSS.

Upon receiving an MLME-RELAY-SEARCH.request primitive, the source DMG STA can discover a list of RDSs in the BSS by transmitting a Relay Search Request frame to the AP or PCP with the destination REDS AID field set to the AID of the destination DMG STA. The MLME of the AP or PCP receiving a Relay Search Request frame shall generate an MLME-RELAY-SEARCH.indication primitive. Upon receiving an MLME-RELAY-SEARCH.response primitive, the AP or PCP shall transmit a Relay Search Response frame addressed to the requesting STA and shall include in the transmitted frame a list of RDSs in the BSS. The MLME of the source DMG STA receiving a Relay Search Response frame shall generate an MLME-RELAY-SEARCH.confirm primitive. After the transmission of the Relay Search Response frame to the source DMG STA, the AP or PCP shall transmit an unsolicited Relay Search Response frame to the destination DMG STA with the Relay Capable STA Info field of the source DMG STA and the list of RDSs that the AP or PCP included in the last Relay Search Response frame transmitted to the source DMG STA.

11.36.2.3 RDS selection procedure

Following the transmission of a Relay Search Response frame, the AP or PCP should schedule within its Extended Schedule element two SPs for each RDS included in the transmitted Relay Search Response frame:

- An SP having as source DMG STA the source REDS and as destination DMG STA the RDS, and with the Beamforming Training field set to 1. The duration of the SP should be such that the source REDS and RDS can complete BF as described in 10.38.
- An SP having as source DMG STA the RDS and as destination DMG STA the destination REDS, and with the Beamforming Training field set to 1. The duration of the SP should be such that the RDS and the destination REDS can complete BF as described in 10.38.

After the RDS completes BF with both the source REDS and destination REDS, the source REDS shall send a Multi-Relay Channel Measurement Request frame to the RDS, which shall respond with the transmission of a Multi-Relay Channel Measurement Report frame back to the source REDS. Following the reception of this frame, the source REDS should perform BF with the destination REDS as described in 10.38, and once BF is completed the source REDS shall transmit a Multi-Relay Channel Measurement Request frame to the destination REDS. In response, the destination REDS shall transmit a Multi-Relay Channel Measurement

Report frame to the source REDS including the channel measurement information between the destination REDS and all RDSs known to the destination REDS. To shorten the time it takes to complete this procedure, STAs can limit BF to the SLS phase only.

Once this procedure is completed, the source REDS becomes aware of all the channel measurement information between the source REDS and zero or more RDSs and between the destination REDS and zero or more RDSs. The source REDS shall then select a single STA to operate as the RDS between the source REDS and the destination REDS. The selection of the RDS is implementation dependent, and it can be based on information contained within an RDS's Relay Capabilities element and channel measurements.

11.36.2.4 RLS procedure

Following the selection of the RDS to be used between the source REDS and the destination REDS, the source REDS receiving an MLME-RLS.request primitive initiates the RLS procedure by sending an RLS Request frame to the selected RDS. The RLS Request frame includes the capabilities and the AIDs of the source REDS, the destination REDS, and the RDS, and the relay transfer parameter set. Upon receiving the RLS Request frame, the RDS shall transmit an RLS Request frame to the destination REDS containing the same information as received within the frame body of the source REDS's RLS Request frame.

The MLME of the destination REDS receiving a Relay Search Request frame shall generate an MLME-RLS.indication primitive. Upon receiving an MLME-RLS.response primitive, the destination REDS shall transmit an RLS Response frame to the RDS with the destination status code field set to SUCCESS if the destination REDS is willing to participate in the RLS, and set to REQUEST_DECLINED if the destination REDS is not willing to participate in the RLS. Upon receiving the RLS Response frame, the RDS shall transmit an RLS Response frame to the source REDS containing the same information as received within the destination REDS's RLS Response frame, with the exception that the RDS shall set the relay status code field to SUCCESS if the RDS is willing to participate in the RLS, and shall set it to REQUEST_DECLINED if the RDS is not willing to participate in the RLS.

The MLME of the source DMG STA receiving an RLS Response frame from the RDS shall generate an MLME-RLS.confirm primitive. Upon receiving an RLS Response frame with the destination status code and relay status code fields set to SUCCESS, the source DMG STA may transmit an RLS Announcement frame to the AP or PCP to indicate that the RLS procedure was successfully completed. If either or both of the destination status code and relay status code fields are nonzero, the RLS procedure is unsuccessful.

Upon the completion of RLS procedure, the source REDS, the destination REDS, and the RDS can redo BF among them.

11.36.3 Relay operation-type change procedure

The source REDS may change the relay operation type from link switching to link cooperation, and vice-versa, if either one of S-D, or S-R, or R-D links becomes unavailable or for other reasons. Link unavailability can be determined by the source DMG STA not receiving expected frames from the destination REDS. To assist in this decision, the source REDS can use the link adaptation procedure (10.41.4) to obtain the quality of a link.

To change the relay operation type within an SP from link cooperation to link switching in a case that the S-D link becomes unavailable, the source REDS shall transmit a ROC Request frame to the RDS with the Link Cooperation subfield set to 0 and the relay-link subfield set to 1. Upon receiving a ROC Request frame, the RDS shall transmit a ROC Request frame to the destination REDS containing the same information as received within the frame body of the source REDS's ROC Request frame. Following the reception of a ROC Request frame, the destination REDS shall respond with a ROC Response frame to the RDS with the status code field set to SUCCESS if the destination REDS accepts to change the operation into link switching, and set to REQUEST_DECLINED if the destination REDS rejects the request. Upon receiving

the ROC Response frame, the RDS shall transmit a ROC Response frame to the source REDS with the status code field set to SUCCESS only if the RDS accepts to change the operation into link switching and the status code field set to SUCCESS in the ROC Response frame received from destination REDS. Otherwise, the RDS shall set the status code field to REQUEST_DECLINED. Upon reception of a ROC Response from the RDS with the status code field set to SUCCESS, the source REDS immediately starts to transmit frames to the destination REDS via the RDS relay link.

To change the relay operation type from link cooperation to link switching in other case that the S-R link becomes unavailable, the source REDS shall a ROC Request frame to the destination REDS with the Link Cooperation subfield set to 0 and the relay-link subfield set to 0. Following the reception of a ROC Request frame, the destination REDS shall respond with a ROC Response frame to the source REDS with the status code field indicating the acceptance or rejection of the request. Upon reception of a ROC Response from the destination REDS with the status code field set to SUCCESS, the source REDS starts to transmit frames to the destination REDS via the direct link in link switching.

To change the relay operation type within an SP from link switching to link cooperation, the source REDS shall transmit a ROC Request frame to the destination REDS via the RDS with the Link Cooperation subfield set to 1. Following the reception of a ROC Request frame from the RDS, the destination REDS shall respond with a ROC Response frame to the source REDS via the RDS with the status code field indicating the acceptance or rejection of the request. Upon reception of a ROC Response frame from the RDS with the status code field set to SUCCESS, the source REDS immediately starts to transmit frames to the destination REDS using the RDS in link cooperation. If a TPA procedure was not performed beforehand since the link switching operation has been continued from the start of relay operation, the STA shall perform the TPA procedure before transmitting using link cooperation.

NOTE—As described in 10.40, during the SP in link cooperation operation the destination REDS has its receive antenna pattern such that it simultaneously covers the links toward both the source REDS and the RDS.

11.36.4 Relay teardown

A source REDS that has successfully completed the RLS procedure with a destination REDS may teardown the relay operation between the source REDS, destination REDS and RDS. To do that, the source REDS shall transmit an RLS Teardown frame to the RDS, destination REDS and AP or PCP of the BSS. Within the RLS Teardown frame, the source REDS shall set the source AID field to the AID of the source REDS, the destination AID field to the AID of the destination REDS and the relay AID field to the AID of the RDS.

A RDS may teardown the relay operation between the source REDS, destination REDS and RDS. To do that, the RDS shall transmit an RLS Teardown frame to the source REDS, destination REDS and AP or PCP of the BSS. Within the RLS Teardown frame, the RDS shall set the source AID field to the AID of the source REDS, the destination AID field to the AID of the destination REDS and the relay AID field to the AID of the RDS.

11.37 Quieting adjacent DMG BSSs

11.37.1 General

An AP that supports QAB shall set the QAB Capability field within the AP's Extended Capabilities element to 1 and shall set the QAB Capability field to 0 otherwise. In addition, if an AP supports QAB, the AP shall also support scheduling SPs as defined in 10.36.6.

11.37.2 Procedure at the requester AP

Upon receipt of an MLME-QAB.request primitive, an AP shall perform the following procedure to start the Quiet Adjacent BSS operation (Figure 11-50):

- If both the requester and responder APs are QAB capable as indicated by the QAB Capability field within the Extended Capabilities element, the requester AP sends a QAB Request frame indicating the duration, period, offset, and number of the quiet intervals. The requester AP may include multiple Quiet Period Request elements in one frame targeting multiple responder APs.
- If a QAB Response frame is received with the matching dialog token and request token with a status code set to a value of SUCCESS, the AP has confirmed the responder AP has scheduled the requested quiet periods, and the MLME shall issue an MLME-QAB.confirm primitive indicating the success of the procedure.
- If a QAB Response frame is received with the matching dialog and request token with a status code set to a value other than SUCCESS, the procedure is considered to have failed, and the MLME shall issue an MLME-QAB.confirm primitive indicating the failure of the procedure.

NOTE—The GAS protocol can be used by an AP to verify the capabilities of another AP.

11.37.3 Procedure at the responder AP

A responder AP shall operate as follows (Figure 11-50):

- When a QAB Request frame matching the BSSID is received from another AP, the MLME shall issue an MLME-QAB.indication primitive.
- Upon receipt of the MLME-QAB.response primitive, the AP shall respond by transmitting a QAB Response frame.
 - If the result code is SUCCESS, the request is accepted. The AP shall use SPs to schedule the quiet period(s) according to the accepted request. The SPs shall have the AP as both source and destination and the AP shall not transmit during the SP. The QAB procedure shall be terminated if the number of quiet intervals exceeds the value of the Repetition Count field specified. Contained in the transmitted QAB Response frame is the copy of the request token and the BSSID of the AP.
 - If the result code is REJECTED, the request has not been fulfilled.

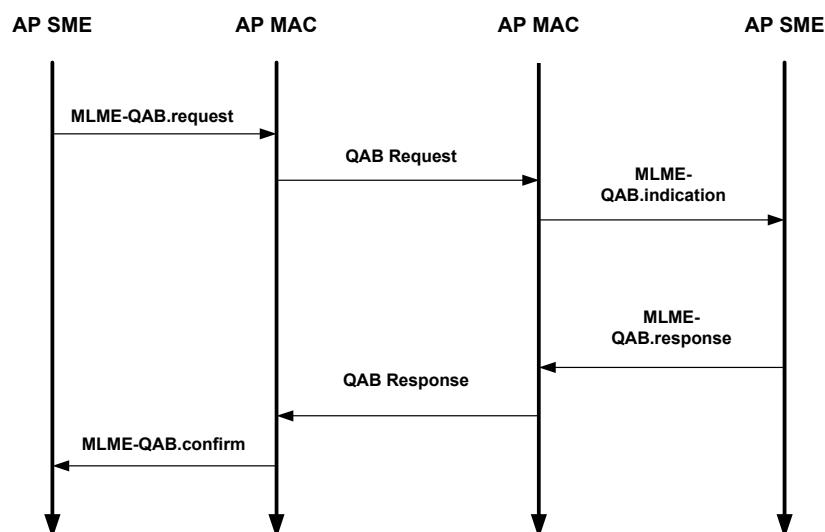

Figure 11-50—Quieting adjacent BSS operation

11.38 DMG beamforming

Upon receipt of an MLME-BF-TRAINING.request primitive, a STA shall undertake beamforming training with the STA indicated by the PeerSTAAddress parameter according to the procedures defined in 10.38. This training shall start with the SLS and shall include the BRP if and only if the RequestBRP parameter of the MLME-BF-TRAINING.request primitive is true.

A STA receiving MLME-BF-TRAINING.request primitive may act as either initiator or responder in the beamforming training.

If the STA indicated by the PeerSTAAddress parameter of a received MLME-BF-TRAINING.request primitive is an AP or PCP of a BSS in which a STA is a member, the STA receiving the MLME-BF-TRAINING.request primitive may perform beamforming training during the A-BFT as described in 10.38.5. Alternatively, the STA receiving the MLME-BF-TRAINING.request primitive may use an SP or a TXOP to perform ISS as described in 10.38.2.2.

A STA receiving the MLME-BF-TRAINING.request primitive shall issue an MLME-BF-TRAINING.confirm primitive on completion of the requested beamforming training or on timeout as specified in 10.38.

A STA that performs beamforming training with a peer STA at the request of the peer STA shall issue an MLME-BF-TRAINING.indication primitive on completion of that beamforming training, or on timeout as specified in 10.38.

Figure 11-51 illustrates an example of the beamforming training procedure in the DTI for a case where the STA receiving the MLME-BF-TRAINING.request primitive acts as initiator.

Figure 11-52 illustrates an example of the beamforming training procedure in the context of a non-AP and non-PCP STA joining an infrastructure BSS or PBSS. In this scenario, the MLME-BF-TRAINING.request primitive is issued by the STA attempting to associate in order that the link be trained to a degree that allows the over-the-air exchanges necessary for association to succeed.

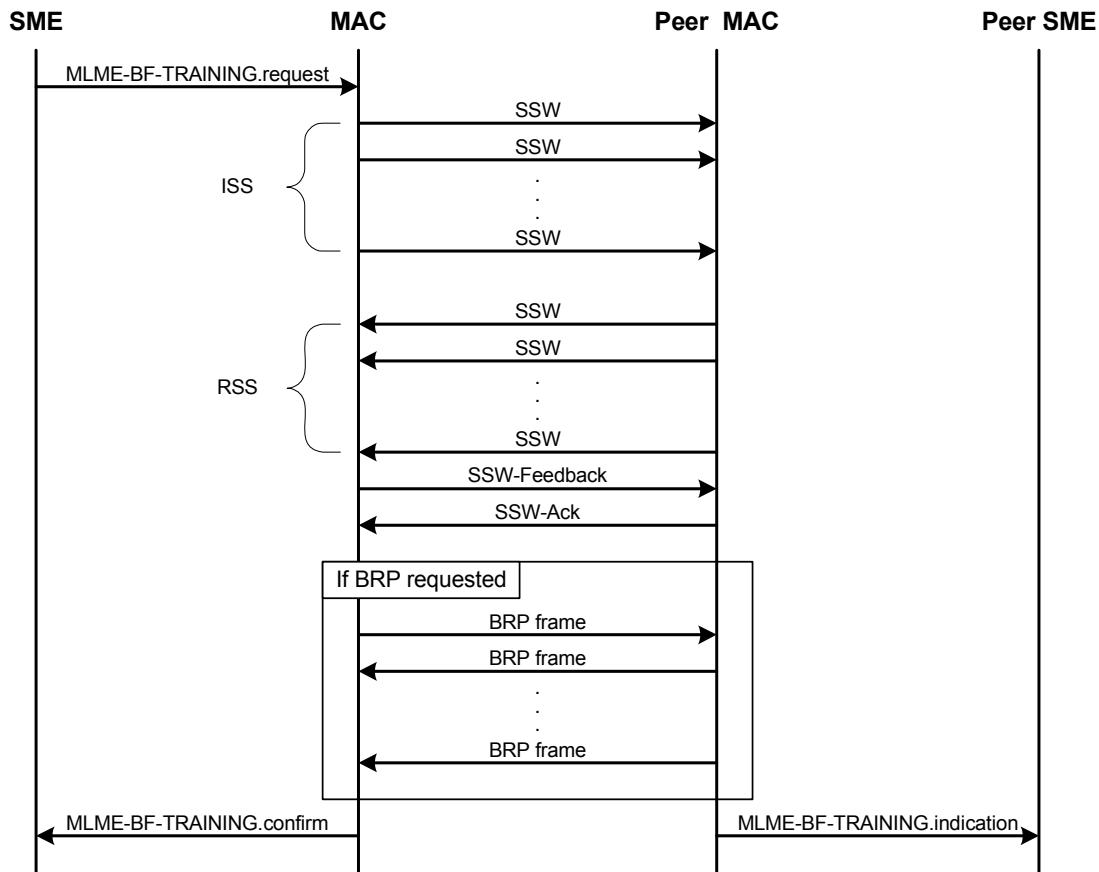

Figure 11-51—Beamforming training procedure in the DTI

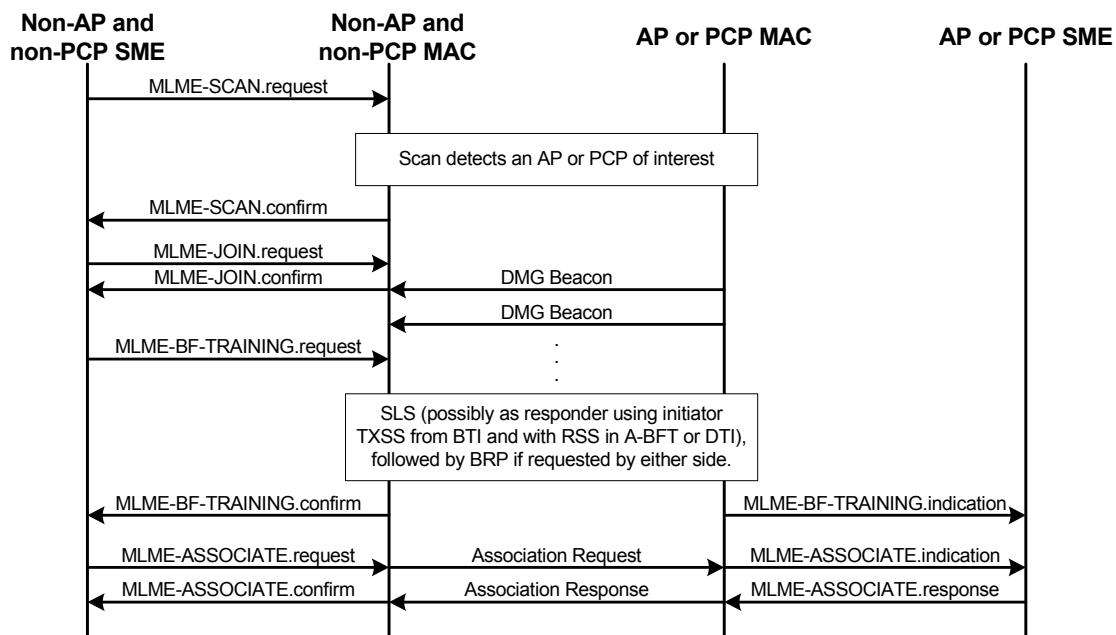

Figure 11-52—Beamforming training when joining an infrastructure BSS or PBSS

11.39 DMG MAC sublayer attributes

The attributes that define some of the MAC characteristics are given in Table 11-23.

Table 11-23—DMG MAC sublayer attribute values

| Attribute | Value |
|-----------------------------------|---|
| aMaxBIDuration | 1000 TUs |
| aMinChannelTime | aMaxBIDuration |
| aMinBTIPeriod | 4 |
| aMinSwitchInterval | $2 \times aMinBTIPeriod$ |
| aMaxSwitchInterval | $16 \times aMinSwitchInterval$ |
| aTSFResolution | 1 μ s |
| aDMGPPMinListeningTime | 150 μ s |
| aSSFramesPerSlot | 4 |
| aSSDuration | $(FSS - 1) \times SBIFS + FSS \times TXTIME(SSW)$ |
| aSSFBDuration | TXTIME(SSW-Feedback) |
| aRTSTimeoutTime | $TXTIME(RTS) + aAirPropagationTime + aRxPHYDelay + aMACProcessingDelay$ |
| aDMGTSFAccuracy | 20 ppm |
| aMinNAVTimersNumber | 2 |
| aCWminDMGIBSS | 3 |
| aMinAllocationDeliveryTime | 300 μ s |
| aMaxABFTAccessPeriod | 2 |
| aDtime | $aSBIFSTime + TXTIME(TPA Request frame)$ |
| aRelayTPATime | $aSBIFSTime + 2 \times aAirPropagationTime + 2 \times aDtime + TXTIME(TPA Request frame) + 2 \times TXTIME(TPA Response frame)$ |
| aMinPPDUDurationForDMGMeasurement | 5.27 μ s |
| aDMGDWSValidPeriod | 60 seconds |

11.40 VHT BSS operation

11.40.1 Basic VHT BSS functionality

A VHT STA has dot11VHTOptionImplemented equal to true.

A STA that is starting a VHT BSS shall be able to receive and transmit at each of the <VHT-MCS, NSS> tuple values indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter of the MLME-START.request primitive and shall be able to receive at each of the <VHT-MCS, NSS> tuple values indicated by the Supported VHT-MCS and NSS Set field of the VHT Capabilities parameter of the MLME-START.request primitive.

A STA for which dot11VHTOptionImplemented is true shall set dot11HighThroughputOptionImplemented to true.

A STA that is a VHT AP or a VHT mesh STA declares its channel width capability in the VHT Capabilities element VHT Capabilities Information field as described in Table 9-249.

A VHT STA shall set the Supported Channel Width Set subfield in its HT Capabilities element HT Capability Information field to 1, indicating that both 20 MHz operation and 40 MHz operation are supported.

At a minimum, a VHT STA sets the Rx MCS Bitmask of the Supported MCS Set field of its HT Capabilities element according to the setting of the Rx VHT-MCS Map subfield of the Supported VHT-MCS and NSS Set field of its VHT Capabilities element as follows: for each subfield Max VHT-MCS For n SS, $1 \leq n \leq 4$, of the Rx VHT-MCS Map field with a value other than 3 (no support for that number of spatial streams), the STA shall indicate support for MCSs $8(n-1)$ to $8(n-1)+7$ in the Rx MCS Bitmask, where n is the number of spatial streams, except for those MCSs marked as unsupported as described in 10.7.12.3.

A STA that is a VHT AP or a VHT mesh STA shall set the STA Channel Width subfield in the HT Operation element HT Operation Information field and the Channel Width, Channel Center Frequency Segment 0 and Channel Center Frequency Segment 1 subfields in the VHT Operation element VHT Operation Information field to indicate the BSS bandwidth as defined in Table 11-24.

Table 11-24—VHT BSS bandwidth

| HT Operation element STA Channel Width field | VHT Operation element Channel Width field | VHT Operation element Channel Center Frequency Segment 1 subfield | BSS bandwidth |
|--|---|---|---------------------------|
| 0 | 0 | 0 | 20 MHz |
| 1 | 0 | 0 | 40 MHz |
| 1 | 1 | 0 | 80 MHz |
| 1 | 1 | CCFS1 > 0 and CCFS1 - CCFS0 = 8 | 160 MHz |
| 1 | 1 | CCFS1 > 0 and CCFS1 - CCFS0 > 16 | 80+80 MHz |
| 1 | 2 | 0 | 160 MHz (deprecated) |
| 1 | 3 | CCFS1 > 0 and CCFS1 - CCFS0 > 16 | 80+80 MHz (deprecated) |

NOTE 1—CCFS0 represents the value of the Channel Center Frequency Segment 0 subfield.
 NOTE 2—CCFS1 represents the value of the Channel Center Frequency Segment 1 subfield.

The setting of the Channel Center Frequency Segment 0 and Channel Center Frequency Segment 1 subfields is shown in Table 11-25.

A VHT STA shall determine the channelization using the combination of the information in the HT Operation element Primary Channel field and the VHT Operation element VHT Operation Information field Channel Center Frequency Segment 0 and Channel Center Frequency Segment 1 subfields (see 21.3.14).

Table 11-25—Setting of Channel Center Frequency Segment 0, Channel Center Frequency Segment 1, and Channel Center Frequency Segment 2 subfields

| BSS bandwidth | VHT Operation element Channel Width field | Setting of the Channel Center Frequency Segment 0 subfield | Setting of the Channel Center Frequency Segment 1 subfield | Setting of the Channel Center Frequency Segment 2 subfield |
|---|---|---|--|--|
| 20, 40 MHz | 0 | dot11CurrentChannelCenterFrequencyIndex0 | 0 | 0 |
| 80 MHz | 1 | dot11CurrentChannelCenterFrequencyIndex0 | 0 | 0 |
| 160 MHz (At least Max VHT NSS support) | 1 | if dot11CurrentPrimaryChannel is greater than dot11CurrentChannelCenterFrequencyIndex0 then dot11CurrentChannelCenterFrequencyIndex0 + 8, else dot11CurrentChannelCenterFrequencyIndex0 - 8 | dot11CurrentChannelCenterFrequencyIndex0 | 0 |
| 160 MHz (Less than Max VHT NSS support) | 1 | if dot11CurrentPrimaryChannel is greater than dot11CurrentChannelCenterFrequencyIndex0 then dot11CurrentChannelCenterFrequencyIndex0 + 8, else dot11CurrentChannelCenterFrequencyIndex0 - 8 | 0 | dot11CurrentChannelCenterFrequencyIndex0 |
| 80+80 MHz (At least Max VHT NSS support) | 1 | dot11CurrentChannelCenterFrequencyIndex0 | dot11CurrentChannelCenterFrequencyIndex1 | 0 |
| 80+80 MHz (Less than Max VHT NSS support) | 1 | dot11CurrentChannelCenterFrequencyIndex0 | 0 | dot11CurrentChannelCenterFrequencyIndex1 |
| 160 MHz (deprecated) | 2 | dot11CurrentChannelCenterFrequencyIndex0 | 0 | 0 |
| 80+80 MHz (deprecated) | 3 | dot11CurrentChannelCenterFrequencyIndex0 | dot11CurrentChannelCenterFrequencyIndex1 | 0 |
| NOTE 1—"At least Max VHT NSS support" means that the NSS support at 160 or 80+80 MHz is at least Max VHT NSS, and therefore the secondary 80 or 160 MHz channel center frequency is signaled through CCFS1. | | | | |
| NOTE 2—"Less than Max VHT NSS support" means that the NSS support at 160 or 80+80 MHz is less than Max VHT NSS, and therefore the secondary 80 or 160 MHz channel center frequency is signaled through CCFS2. | | | | |
| NOTE 3—for NSS support, see Table 9-75 and Table 9-250. | | | | |

A VHT AP or a VHT mesh STA shall set the HT Operation element HT Operation Information field Secondary Channel Offset subfield to indicate the secondary 20 MHz channel as defined in Table 9-168, if the BSS bandwidth is more than 20 MHz.

A VHT STA that is a member of a VHT BSS shall not transmit a 20 MHz VHT PPDU on a channel other than the primary 20 MHz channel, except for a 20 MHz VHT PPDU transmission on an off-channel TDLS direct link as constrained by 11.23.6.5.2.

A VHT STA that is a member of a VHT BSS with a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz BSS bandwidth shall not transmit a 40 MHz VHT PPDU that does not use the primary 40 MHz channel, except for a 40 MHz VHT PPDU transmission on an off-channel TDLS direct link.

A VHT STA that is a member of a VHT BSS with an 80 MHz, 160 MHz, or 80+80 MHz BSS bandwidth shall not transmit an 80 MHz VHT PPDU that does not use the primary 80 MHz channel, except for an 80 MHz VHT PPDU transmission on an off-channel TDLS direct link.

A VHT STA that is a member of a VHT BSS with a 160 MHz or 80+80 MHz BSS bandwidth shall not transmit a 160 MHz or 80+80 MHz VHT PPDU that does not use the primary 80 MHz channel and the secondary 80 MHz channel, except for a 160 MHz or 80+80 MHz VHT PPDU transmission on an off-channel TDLS direct link.

A VHT STA shall not transmit to a second VHT STA using a bandwidth that is not indicated as supported in the Supported Channel Width Set subfield in the HT Capabilities element or in the VHT Capabilities Information field of the VHT Capabilities element received from that VHT STA.

A STA shall not transmit an MPDU in a VHT PPDU to a STA that exceeds the maximum MPDU length capability indicated in the VHT Capabilities element received from the recipient STA.

A VHT AP shall set the RIFS Mode field in the HT Operation element to 0.

VHT BSS operation with less than Max VHT NSS support is enabled as defined in Table 11-26 and disabled otherwise, in which case the Channel Center Frequency Segment 2 subfield of the HT Operation element shall be 0.

Table 11-26—Extended NSS channel width

| HT Operation element STA Channel Width field | VHT Operation element Channel Width field | VHT Operation element CCFS1 field | HT Operation element CCFS2 field | Extended NSS channel width |
|--|---|-----------------------------------|--|----------------------------|
| 1 | 1 | 0 | CCFS2 > 0 and CCFS2 – CCFS0 = 8 (40 MHz apart) | 160 MHz |
| 1 | 1 | 0 | CCFS2 > 0 and CCFS2 - CCFS0 > 16 (> 80 MHz apart) | 80+80 MHz |
| 1 | 1 | 0 | CCFS2 > 0 and CCFS2 – CCFS0 < 8 (< 40 MHz apart) | Reserved |
| 1 | 1 | 0 | CCFS2 > 0 and 8 < CCFS2 – CCFS0 ≤ 16 (> 40 MHz and ≤ 80 MHz apart) | Reserved |

NOTE 1—CCFS0 represents the value of the Channel Center Frequency Segment 0 subfield of the VHT Operation element.

NOTE 2—CCFS2 represents the value of the Channel Center Frequency Segment 2 subfield of the HT Operation element.

When VHT BSS operation with less than Max VHT NSS support is enabled, the NSS support is determined based on the Extended NSS channel width and the VHT Capabilities element per Table 9-250 and Table 9-75.

11.40.2 Channel selection methods for a VHT BSS

Before a STA starts a VHT BSS, the STA shall perform a minimum of dot11VHTOBSSScanCount OBSS scan operations to search for existing BSSs (see 11.40.3).

If an AP or a mesh STA starts a VHT BSS that occupies some or all channels of any existing BSSs, the AP or mesh STA may select a primary channel of the new VHT BSS that is identical to the primary channel of any one of the existing BSSs.

If an AP or a mesh STA selects a primary channel for a new VHT BSS with a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz BSS bandwidth from among the channels on which no beacons are detected during the OBSS scans, then the selected primary channel meets the following conditions:

- It shall not be identical to the secondary 20 MHz channel of any existing BSSs with a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz BSS bandwidth.
- It should not overlap with the secondary 40 MHz channel of any existing BSSs with a 80 MHz, 160 MHz or 80+80 MHz BSS bandwidth.

A STA that is an AP or mesh STA should not start a VHT BSS with a 20 MHz BSS bandwidth on a channel that is the secondary 20 MHz channel of any existing BSSs with a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz BSS bandwidth, or is overlapped with the secondary 40 MHz channel of any existing BSSs with a 160 MHz or 80+80 MHz BSS bandwidth.

NOTE—An AP or a mesh STA operating a VHT BSS with a 40 MHz, 80 MHz, 160 MHz, or 80+80 MHz BSS bandwidth, on detecting an OBSS whose primary channel is the AP's or the mesh STA's secondary 20 MHz channel, might switch to 20 MHz BSS operation and/or move to a different channel.

11.40.3 Scanning requirements for VHT STA

An OBSS scan operation is a passive or active scan of a set of channels that are potentially affected by VHT BSS operation (see 11.1.4.1). Each channel in the set may be scanned more than once during a single OBSS scan operation. OBSS scans are performed by STAs that start a VHT BSS.

During an individual scan within an OBSS scan operation, the minimum per-channel scan duration is dot11OBSSScanPassiveDwell TUs (for a passive scan) or dot11OBSSScanActiveDwell TUs (for an active scan). During an OBSS scan operation, each channel in the set is scanned at least once per dot11BSSWidthTriggerScanInterval seconds, and the minimum total scan time (i.e., the sum of the scan durations) per channel within a single OBSS scan operation is dot11OBSSScanPassiveTotalPerChannel TUs (for a passive scan) or dot11OBSSScanActiveTotalPerChannel TUs (for an active scan).

NOTE—The values provided in the previous paragraph are minimum requirements. For some combinations of parameter values the minimum might be exceeded for some parameters in order to meet the minimum value constraints of other parameters.

11.40.4 Channel switching methods for a VHT BSS

A VHT AP announces a switch of operating channel by either of the following:

- Using the Channel Switch Announcement element, Channel Switch Announcement frame, or both, following the procedure described in 11.9.8.2
- Using the Extended Channel Switch Announcement element, Extended Channel Switch Announcement frame, or both, following the procedure described in 11.10

A VHT mesh STA announces a switch attempt of operating channel by either of the following:

- Using the Channel Switch Announcement element, Channel Switch Announcement frame, or both, following the procedure described in 11.9.8.4
- Using the Extended Channel Switch Announcement element, Extended Channel Switch Announcement frame, or both, following the procedure described in 11.10

A VHT AP or a VHT mesh STA may also announce a switch of BSS bandwidth, a new Country String field (possibly including a new Operating Class table number), new operating classes, or new TPC parameters for the BSS that come into effect at the same time as the switch of operating channel.

The New Channel Number field in the Channel Switch Announcement element, Extended Channel Switch Announcement element, Channel Switch Announcement frame, or Extended Channel Switch Announcement frame identifies the primary 20 MHz channel after the switch. The value of the New Channel Number field is set to the value that dot11CurrentPrimaryChannel (see 21.3.14) will have after the switch.

If a Channel Switch Announcement frame is used to announce a switch to a 20 MHz BSS bandwidth, then neither a Wide Bandwidth Channel Switch element nor a Secondary Channel Offset element shall be present in the frame, except that a Secondary Channel Offset element may be present in a Channel Switch Announcement frame if the Secondary Channel Offset field within the Secondary Channel Offset element is set to SCN.

If a Channel Switch Announcement element is used to announce a switch to a 20 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in a Channel Switch Wrapper element shall not be present in the same frame.

If an Extended Channel Switch Announcement element in a Beacon or Probe Response frame or an Extended Channel Switch Announcement frame is used to announce a switch to a 20 MHz BSS bandwidth, then neither a Wide Bandwidth Channel Switch element nor a Wide Bandwidth Channel Switch subelement shall be present in the same frame.

NOTE—A Secondary Channel Offset element is never present with the Extended Channel Switch Announcement element or in the Extended Channel Switch Announcement frame. Instead, the indicated operating class within the Extended Channel Switch Announcement element or frame is used to differentiate between a BSS BSS bandwidth of 20 MHz and a BSS bandwidth greater than 20 MHz as well as indicate the location of the secondary 20 MHz channel. For a switch to a 20 MHz BSS bandwidth, the operating class indicated within the Extended Channel Switch Announcement element or frame has a channel spacing of 20 MHz. For a switch to an BSS bandwidth greater than 20 MHz, the operating class indicated within the Extended Channel Switch Announcement element or frame has a channel spacing of 40 MHz.

If a Channel Switch Announcement frame is used to announce a switch to a 40 MHz BSS bandwidth, then the following apply:

- The Secondary Channel Offset element shall be present in the frame.
- The Wide Bandwidth Channel Switch shall not be present in the frame.

If a Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 40 MHz BSS bandwidth, then the Wide Bandwidth Channel Switch subelement in the Channel Switch Wrapper element shall also be present in the same frame.

If an Extended Channel Switch Announcement element in a Beacon or Probe Response frame is used to announce a switch to a 40 MHz BSS bandwidth, then the Wide Bandwidth Channel Switch subelement in the Channel Switch Wrapper element may be present in the same frame.

NOTE—The indicated operating class within the Extended Channel Switch Announcement element identifies the bandwidth and the relative position of the primary 20 MHz and secondary 20 MHz channels. Hence a Wide Bandwidth Channel Switch subelement is unnecessary when the Extended Channel Switch Announcement element is used for a channel switch to a 40 MHz bandwidth.

If a Channel Switch Announcement frame is used to announce a switch to an 80 MHz, 80+80 MHz, or 160 MHz BSS bandwidth, then both the Secondary Channel Offset element and the Wide Bandwidth Channel Switch element shall be present in the frame.

If a Channel Switch Announcement element or an Extended Channel Switch Announcement element is used to announce a switch to an 80 MHz, 80+80 MHz, or 160 MHz BSS bandwidth, then a Wide Bandwidth Channel Switch subelement in the Channel Switch Wrapper element shall be present in the same frame.

If an Extended Channel Switch Announcement frame is used to announce a switch to an 80 MHz, 80+80 MHz, or 160 MHz BSS bandwidth, then the Wide Bandwidth Channel Switch element shall be present in the frame.

If an Extended Channel Switch Announcement element or Extended Channel Switch Announcement frame is used to announce a switch to an 80 MHz, 80+80 MHz, or 160 MHz BSS BSS bandwidth, then

- The value of the New Operating Class field identifies the primary 40 MHz channel, and
- The Operating Triplet fields within the New Country subelement or element, respectively, shall indicate all of the operating classes for the switched BSS.

If new BSS TPC parameters are announced that come into effect at the same time as the channel switch, then if an AP, IBSS STA or mesh STA is extended spectrum management capable, it shall include

- At least one New Transmit Power Envelope element in a transmitted Channel Switch Announcement frame or Extended Channel Switch Announcement frame and
- At least one New Transmit Power Envelope subelement in a transmitted Channel Wrapper element in Beacon and Probe Response frames.

A recipient STA in the BSS that is extended spectrum management capable and that has dot11SpectrumManagementRequired or dot11RadioMeasurementActivated equal to true and that maintains association with the BSS after the switch shall use the parameters in these received elements and subelements in the recipient STA's TPC calculations for the new operating channel and BSS bandwidth (see 11.8). If both New Transmit Power Envelope elements and New Transmit Power Envelope subelements are transmitted for the switch, the set of New Transmit Power Envelope elements and set of subelements shall contain the same set of values for the Local Maximum Transmit Power Unit Interpretation subfield, and New Transmit Power Envelope elements and subelements that have the same value of the Local Maximum Transmit Power Unit Interpretation subfield shall also have the same values for their other fields.

If a new country string, new operating classes or both, are coming into effect at the same time as the channel switch, then if an AP, IBSS STA or mesh STA is extended spectrum management capable, it shall include

- A New Country element in a transmitted Extended Channel Switch Announcement frame and
- A New Country subelement in a transmitted Channel Wrapper element.

The New Country element or subelement shall contain all of the Operating Classes for the BSS after the switch. The New Country element or subelement, transmitted in an Extended Channel Switch Announcement frame or in the same frame as an Extended Channel Switch Announcement element, respectively, shall include one Operating Triplet field that contains the same Operating Class as the New Operating Class field in the Extended Channel Switch Announcement frame or Extended Channel Switch Announcement element. A recipient STA in the BSS that is extended spectrum management capable and that has dot11MultiDomainCapabilityActivated, dot11SpectrumManagementRequired, or dot11RadioMeasurementActivated equal to true and that maintains association with the BSS after the switch

shall use the parameters in these received elements and subelements in order to maintain regulatory compliance. If both New Country elements and New Country subelements are transmitted for the switch, their fields shall be the same.

A Channel Switch Wrapper element shall not be included in Beacon or Probe Response frames if the element contains zero subelements.

NOTE—Channel Switch Wrapper is not defined to carry subelements in the case of a switch to 20 MHz and when no change to the country string, operating classes or TPC parameters are announced.

A VHT STA uses only the Transmit Power Envelope element, not the Power Constraint element, for TPC of 80 MHz, 160 MHz, and 80+80 MHz transmissions. In the Country element, a VHT STA shall include zero Subband Triplet fields in an Operating/Subband Sequence field that contains an Operating Class field for which the “Channel Spacing (MHz)” column in the applicable table in Annex E equals 80 or 160.

An AP that switches the BSS to a lower BSS bandwidth may recalculate the TS bandwidth budget and may delete one or more active TSs by invoking the MLME-DELTS.request primitive with a ReasonCode value of SERVICE_CHANGE_PRECLUDES_TS.

A VHT STA that is a member of an IBSS shall not transmit values in the Wide Bandwidth Channel Switch element that change the frequency ordering of the primary 40 MHz channel and the secondary 40 MHz channel from the ordering of the most recently adopted operating channel, if the operating channel includes a secondary 40 MHz channel. A VHT STA that is a member of an IBSS shall not transmit values in the Wide Bandwidth Channel Switch element that change the frequency ordering of the primary 80 MHz channel and the secondary 80 MHz channel from the ordering of the most recently adopted operating channel, if the operating channel includes a secondary 80 MHz channel.

11.40.5 NAV assertion in a VHT BSS

A VHT STA shall update its NAV as described in 10.3.2.4 using the Duration/ID field value in any frame that does not have an RA matching the STA’s MAC address and that was received in a 20 MHz PPDU in the primary 20 MHz channel or received in a 40 MHz PPDU in the primary 40 MHz channel or received in an 80 MHz PPDU in the primary 80 MHz channel or received in a 160 MHz or 80+80 MHz PPDU.

NOTE—The PHY might filter out a PPDU as described in 21.3.20 or not receive a PPDU due to VHT TXOP power saving described in 11.2.3.19. If so, frames in the PPDU are not received by the MAC and have no effect on the NAV.

11.40.6 VHT STA antenna indication

A VHT STA that does not change its Rx antenna pattern after association shall set the Rx Antenna Pattern Consistency subfield in the VHT Capabilities Information field to 1; otherwise, the STA shall set the Rx Antenna Pattern Consistency subfield in the VHT Capabilities Information field to 0.

A VHT STA that does not change its Tx antenna pattern after association shall set the Tx Antenna Pattern Consistency subfield in the VHT Capabilities Information field to 1; otherwise, the STA shall set the Tx Antenna Pattern Consistency subfield in the VHT Capabilities Information field to 0.

11.40.7 Basic VHT-MCS and NSS set operation

The basic VHT-MCS and NSS set is the set of <VHT-MCS, NSS> tuples that are supported by all VHT STAs that are members of a VHT BSS. It is established by the STA that starts the VHT BSS, indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter in the MLME-START.request primitive. Other VHT STAs determine the basic VHT-MCS and NSS set from the Basic VHT-MCS And NSS Set field of the VHT Operation element in the BSSDescription derived through the scan mechanism (see 11.1.4.1).

A VHT STA shall not attempt to join (MLME-JOIN.request primitive) a BSS unless it supports (i.e., is able to both transmit and receive using) all of the <VHT-MCS, NSS> tuples in the basic VHT-MCS and NSS set.

NOTE—A VHT STA does not attempt to (re)associate with a VHT AP unless the STA supports (i.e., is able to both transmit and receive using) all of the <VHT-MCS, NSS> tuples in the Basic VHT-MCS And NSS Set field in the VHT Operation element transmitted by the AP because the MLME-JOIN.request primitive is a necessary precursor to (re)association.

11.40.8 Extended NSS BW Support Signaling

If dot11VHTExtendedNSSBWCapable is false, a STA shall set the Extended NSS BW Support subfield of the VHT Capabilities Information field to 0 in VHT Capability elements that it transmits, otherwise, the subfield may be set to 1, 2 or 3 as indicated in 9.4.2.158.2.

If dot11VHTExtendedNSSBWCapable is false, a STA shall set the VHT Extended NSS BW Capable subfield of the Supported VHT-MCS and NSS Set field to 0 in VHT Capability elements that it transmits, otherwise, the subfield shall be set to 1.

11.41 Group ID management operation

An AP determines the possible combinations of STAs that can be addressed by a VHT MU PPDU by assigning STAs to groups and to specific user positions within those groups.

Assignments or changes of user positions corresponding to one or more Group IDs shall be performed using a Group ID Management frame defined in 9.6.23.3.

A STA may be assigned to multiple groups by setting multiple subfields of the Membership Status Array field (see 9.4.1.54) to 1 in the Group ID Management frame addressed to that STA.

A STA's user position in each group of which the STA is a member is indicated by the associated subfield in the User Position Array field (see 9.4.1.55) in the Group ID Management frame addressed to the STA. For each Group ID, an AP may assign the same user position to multiple STAs. A STA shall have only one user position in each group of which the STA is a member.

An AP may transmit a Group ID Management frame only if dot11VHTOptionImplemented is true. A Group ID Management frame shall not be sent to a VHT STA that does not have the MU Beamformee Capable field in the VHT Capabilities element equal to 1.

A Group ID Management frame shall be sent as an individually addressed frame.

A STA's MLME that receives a Group ID Management frame with a RA matching its MAC address shall issue a PHYCONFIG_VECTOR primitive with the GROUP_ID_MANAGEMENT parameter based on the content of the received Group ID Management frame in order to configure the following lookup tables in the PHY:

- a) group ID to Membership Status, denoted by MembershipStatusInGroupID[g] for $1 \leq g \leq 62$
- b) group ID to User Position, denoted by UserPositionInGroupID[g] for $1 \leq g \leq 62$

Group ID values of 0 and 63 are used for SU PPDU and the PHY filtering of such PPDUs is controlled by the PHYCONFIG_VECTOR primitive LISTEN_TO_GID00 and LISTEN_TO_GID63 parameters. The User Position in Group ID information is interpreted by a STA receiving a VHT MU PPDU as explained in 21.3.11.4.

Transmission of a Group ID Management frame to a STA and any associated acknowledgment from the STA shall complete before the transmission of a VHT MU PPDU to the STA.

A VHT MU PPDU shall be transmitted to a STA based on the content of the Group ID Management frame most recently transmitted to the STA and for which an acknowledgment was received.

11.42 Notification of operating mode changes

A STA in which `dot11OperatingModeNotificationImplemented` is true shall set the Operating Mode Notification field in the Extended Capabilities element to 1. A VHT STA shall set `dot11OperatingModeNotificationImplemented` to true. A STA in which `dot11OperatingModeNotificationImplemented` is true is referred to as *operating mode notification capable*.

A STA that is operating mode notification capable and that transmits an Association Request, Reassociation Request, TDLS Setup Response, TDLS Setup Confirm, Mesh Peering Open, or Mesh Peering Confirm frame to a STA that is operating mode notification capable should notify the recipient STA of a change in its operating mode by including the Operating Mode Notification element in the frame.

A first STA that is operating mode notification capable should notify a second STA that is operating mode notification capable of a change in its operating mode by transmitting an Operating Mode Notification frame to the second STA if the first STA has established any of the following with a second STA:

- An association with an AP
- A TDLS link
- A DLS link
- A Mesh Peer relationship

NOTE—Notify Channel Width frames and elements are used to signal STA operating channel width changes to and from STAs that are not operating mode notification capable.

The Operating Mode field in the Operating Mode Notification frame or the Operating Mode Notification element together with the Supported Channel Width set field and the Extended NSS BW Support field of the VHT Capabilities element indicates the transmitting STA's receive bandwidth and NSS capabilities. See 10.7.12.1.

The notification of a change in supported spatial streams should occur prior to a decrease in the maximum number of spatial streams and following an increase in the maximum number of spatial streams.

The notification of a change in operating bandwidth should occur prior to a decrease in the operating channel width and following an increase in the operating channel width.

A STA shall not transmit an individually addressed frame that contains the Operating Mode field unless the recipient is operating mode notification capable.

An AP should notify associated STAs of a change in the maximum number of spatial streams it is able to receive through one or more of the following mechanisms:

- Using individually addressed Operating Mode Notification frames
- Including the Operating Mode Notification element in Beacon frames for a period of time to allow STAs in PS mode to receive the notification

NOTE—An AP cannot change the maximum number of spatial streams it is able to receive from HT STAs that are not operating mode notification capable.

The notification should occur prior to a decrease in the maximum number of spatial streams and following an increase in the maximum number of spatial streams.

An AP should notify associated STAs of a change in its operating channel width through one or more of the following mechanisms:

- Using the Channel Switch Announcement element, Channel Switch Announcement frame or both following the procedure defined in 11.9.8.2
- Using the Extended Channel Switch Announcement element, Extended Channel Switch Announcement frame or both, following the procedure described in 11.10
- Using individually addressed Operating Mode Notification frames and/or Notify Channel Width frames
- Using the STA Channel Width field in the HT Operation element and/or Channel Width field in the VHT Operation element

The notification should occur prior to a decrease in the operating channel width and following an increase in the operating channel width.

A VHT AP that has at least one VHT STA associated and that indicates a channel width change using management action frame(s) shall transmit Operating Mode Notification frame(s) to signal the channel width change. A VHT AP that has at least one non-VHT HT STA associated and that indicates a channel width change using management action frame(s) shall transmit Notify Channel Width frame(s) to signal the channel width change.

A VHT STA shall not transmit an individually addressed Notify Channel Width frame to a VHT STA.

A VHT STA associated with a VHT AP shall ignore Notify Channel Width frames received from the VHT AP.

An HT AP that is not a VHT AP that changes its operating channel width shall indicate the new operating channel width in the STA Channel Width field in the HT Operation element. A VHT AP that changes its operating channel width shall indicate the new operating channel width in the Channel Width field in the VHT Operation element and STA Channel Width field in the HT Operation element (see Table 11-24).

An AP shall not include the Operating Mode Notification element in Beacon, Probe Response, Association Response, and Reassociation Response frames when not changing the maximum number of spatial streams the AP is able to receive.

A STA shall not transmit an Operating Mode field with the value of the Rx NSS subfield indicating a number of spatial streams not supported by the recipient STA. The number of spatial streams supported by the recipient STA is reported in the Supported Rates and BSS Membership Selectors element, Extended Supported Rates and BSS Membership Selectors element, Supported MCS Set, or Supported VHT-MCS and NSS Set field transmitted in Management frames by the recipient STA.

A STA shall not transmit an Operating Mode field with the value of the Channel Width subfield indicating a bandwidth not supported by the STA, as reported in the Supported Channel Width Set subfield in the HT Capability Information field or in the VHT Capabilities Information field in Management frames transmitted by the STA.

A STA that is operating mode notification capable shall not transmit a PPDU to a STA that uses a bandwidth that is greater than the channel width indicated in the most recently received Operating Mode Notification element or Operating Mode Notification frame from that STA. A STA that is operating mode notification capable shall not transmit a PPDU to a STA that uses a greater number of spatial streams than indicated in the most recently received Operating Mode Notification element or Operating Mode Notification frame received from that STA.

NOTE 1—The number of spatial streams might be further restricted if the receiving STA is in SM power save mode (see 11.2.6).

NOTE 2—To avoid possible frame loss, a VHT STA that sends an individually addressed Operating Mode Notification frame to a second VHT STA indicating reduced operating channel width and/or reduced active receive chains can continue with its current operating channel width and active receive chains until it infers that the second STA has processed this notification. The first VHT STA might make this inference from either of the following:

- By receiving a frame addressed to itself from the second VHT STA in a PPDU with a bandwidth and N_{SS} that are less than or equal to the channel width and N_{SS} , respectively, indicated in the Operating Mode Notification frame
- Based on the passage of time in some implementation dependent way, which is outside the scope of this standard

NOTE 3—It might take a long time for a STA to change its operating mode following the transmission of the Operating Mode Notification frame and during that time the STA might not be able to receive frames resulting in frame loss. If a non-AP STA cannot tolerate frame loss during that period it can set the Power Management subfield of the Frame Control field of the Operating Mode Notification frame to 1 to indicate that the STA has entered power save. When the non-AP STA has completed its operating mode change, it can send another frame (such as a QoS Null) with the Frame Control Power Management subfield set to 0 to indicate that the STA has exited power save.

11.43 Basic TVHT BSS functionality

The STA that is creating a TVHT BSS shall be able to receive and transmit at each of the <VHT-MCS, NSS> tuple values indicated by the Basic VHT-MCS And NSS Set field of the VHT Operation parameter of the MLME-START.request primitive and shall be able to receive at each of the <VHT-MCS, NSS> tuple values indicated by the Supported VHT-MCS and NSS Set field of the VHT Capabilities parameter of the MLME-START.request primitive. A STA for which dot11VHTOptionImplemented is true shall set dot11VHTOptionImplemented to true.

A TVHT AP declares its channel width capability in the VHT Capabilities element VHT Capabilities Information field, as defined in 9.4.2.158.

A TVHT AP shall set the Channel Width subfield in the TVHT Operation Information field to indicate the BSS bandwidth and transmitted PPDU type as defined in Table 11-27.

Table 11-27—TVHT BSS bandwidth

| TVHT Operation element Channel Width field | BSS bandwidth | PPDU type |
|--|---------------|--------------|
| 0 | TVHT_W | TVHT_MODE_1 |
| 1 | TVHT_2W | TVHT_MODE_1 |
| | | TVHT_MODE_2C |
| 2 | TVHT_W+W | TVHT_MODE_1 |
| | | TVHT_MODE_2N |
| 3 | TVHT_4W | TVHT_MODE_1 |
| | | TVHT_MODE_2C |
| | | TVHT_MODE_4C |
| 4 | TVHT_2W+2W | TVHT_MODE_1 |
| | | TVHT_MODE_2C |
| | | TVHT_MODE_4N |

A TVHT non-AP STA that receives a frame containing a TVHT Operation element shall determine the channelization based on the Channel Center Frequency Segment0, Channel Center Frequency Segment1, and Primary Channel Number subfields of the TVHT Operation Information field (see 22.3.14).

A TVHT STA that is a member of a TVHT BSS shall transmit a TVHT_MODE_1 PPDU only on the primary TVHT_W channel, except for a TVHT_MODE_1 PPDU transmission on an off-channel TDLS direct link.

A TVHT STA that is a member of a TVHT BSS with a TVHT_2W, TVHT_4W, or TVHT_W+W BSS bandwidth shall not transmit a TVHT_MODE_2C or TVHT_MODE_2N PPDU that does not use the primary TVHT_W channel and the secondary TVHT_W channel, except for a TVHT_MODE_2C, TVHT_MODE_4C, or TVHT_MODE_2N PPDU transmission on an off-channel TDLS direct link.

A TVHT STA that is a member of a TVHT BSS with a TVHT_4W or TVHT_2W+2W BSS bandwidth shall not transmit a TVHT_MODE_4C or TVHT_MODE_4N PPDU that does not use the primary TVHT_2W channel and the secondary TVHT_2W channel, except for a TVHT_MODE_4C or TVHT_MODE_4N PPDU transmission on an off-channel TDLS direct link.

A TVHT STA shall not transmit to a TVHT STA using a bandwidth that is not indicated as supported in the VHT Capabilities element or Operating Mode Notification frame recently received from that TVHT STA.

In a TVHT BSS, the primary TVHT_W channel is the primary channel.

11.44 Operation under the control of a GDB

11.44.1 General

When a STA implements support for one or more of the procedures described in this subclause, it shall set dot11TVHTOptionImplemented to true. When dot11TVHTOptionImplemented is true and a STA is initialized for operation in a band that requires GDB control, then dot11GDDActivated shall be true.

In some regulatory domains, STAs shall consult a GDB to determine permissible operating frequencies and parameters before transmitting. Such STAs may operate as geolocation database dependent (GDD) enabling STAs, which are required by regulation to provide their identification, geolocation, and other information to the GDB as specified by regulatory authorities. Other STAs are permitted to transmit when enabled by a GDD enabling STA. Such STAs operate as GDD dependent STAs.

Subclause 11.44 describes procedures for STAs when they are operating under the control of a GDB to satisfy regulatory requirements. For operation under such restrictions, GDD dependent STAs operate according to the control procedures of a GDD enabling STA that enables their operation. The frame exchange sequence between GDD enabling STA and GDD dependent STAs for enabling their operation occurs in State 4 (see 11.3.1).

A GDD enabling STA is a STA that is able to access a GDB and to obtain the information about the permitted frequencies and other information for use in its location. A GDD enabling STA or geolocated non-AP STA populates its dot11STALCITable with location information by a means that has received regulatory approval and is outside the scope of this standard. When location information is set in dot11STALCITable,

the STA sets dot11GeolocationCapabilityActivated. The current dot11STALCITable allows management access to the location information that is the basis for operation. A GDD enabling STA may transmit a GDD enabling signal and may enable operations of GDD dependent STAs.

A GDD dependent STA is a STA that is under the control of a GDD enabling STA.

The GDD enablement procedure for GDD dependent STAs and the operating rules for GDD enabling and GDD dependent STAs are defined in the following subclauses.

11.44.2 GDD enabling STA operation

A GDD enabling STA may transmit a GDD enabling signal in-band on an available frequency to indicate that it offers GDD enablement service.

The GDD enabling signal is a Beacon frame with an Extended Capabilities element that contains a Geodatabase Inband Enabling Signal field with a value of ‘1’. A GDD dependent STA shall not transmit any frames before it receives a GDD enabling signal over the air directly from a GDD enabling STA.

In some regulatory domains the GDD enabling STA may be required to have secure authentication or association with the GDD dependent STA before it sends the GDD Enablement Response frame. If required by regulation, the GDD enabling STA may contact a GDB to verify that the requesting GDD dependent STA is authorized to operate in the frequency band.

Upon receipt of a GDD Enablement Request frame from a GDD dependent STA, the GDD enabling STA sends a GDD Enablement Response frame with either of the following results:

- a) The Status Code field set to SUCCESS to indicate the successful enablement of the requesting GDD dependent STA
- b) The Status Code field set to ENABLEMENT DENIED or INVALID_PARAMETERS or RESTRICTION FROM AUTHORIZED GDB, in which case the GDD enablement request has been denied

A GDD enabling STA may issue an unsolicited GDD Enablement Response frame with a Status Code AUTHORIZATION DEENABLED to notify a GDD dependent STA to cease its transmissions and change its GDD enablement state to *Unenabled*. When an unsolicited GDD Enablement Response frame with a Status Code AUTHORIZATION DEENABLED is transmitted, the WSM element is not included.

11.44.3 GDD dependent STA operation

A GDD dependent STA is configured with a GDD enablement state variable which is set to one of the following three states: *Unenabled*, *AttemptingGDDEnablement*, or *GDDEnabled*. A GDD dependent STA begins operation by setting its GDD enablement state variable to *Unenabled* and operates in receive-only mode within the band, passively scanning channels for a GDD enabling signal from a GDD enabling STA.

A typical state machine implementation of GDD dependent STA operation under GDD is provided in Figure 11-53.

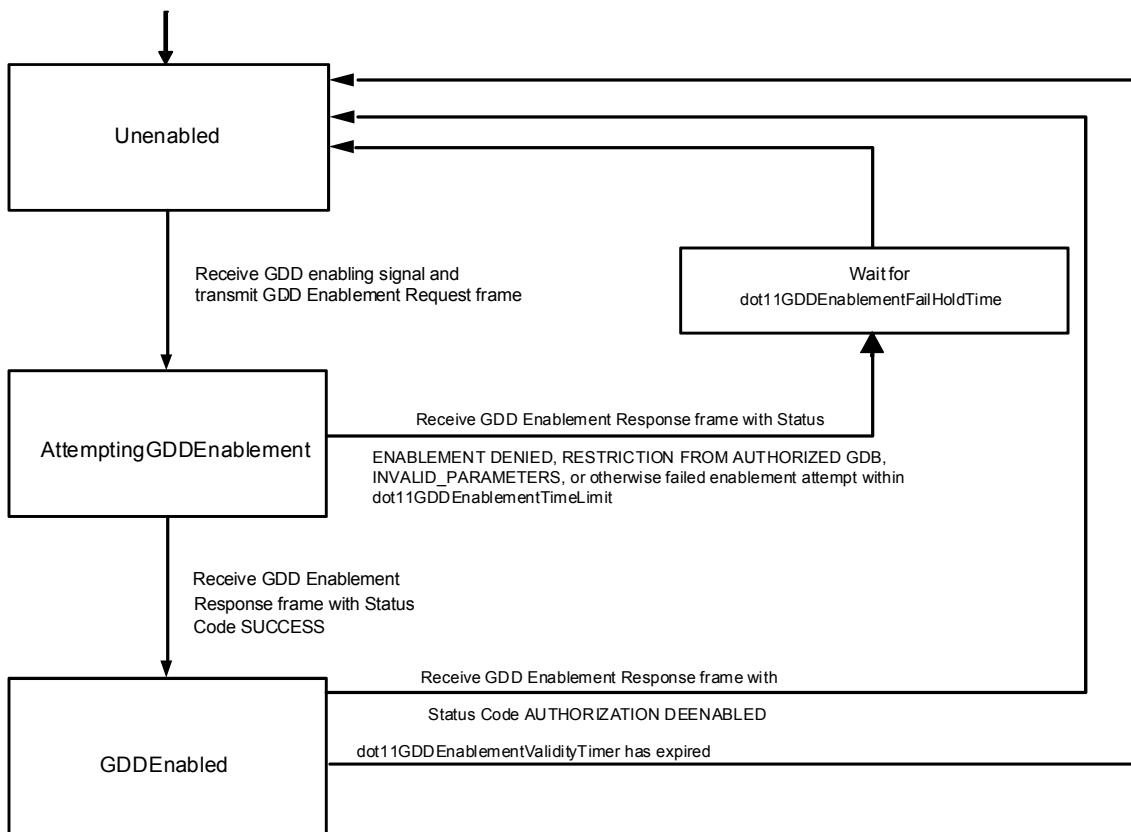

Figure 11-53—GDD dependent STA state transition diagram

A GDD dependent STA shall not transmit any frames unless it has received a valid GDD enabling signal from a GDD enabling STA.

A GDD dependent STA that is able to receive a valid GDD enabling signal, but has not been enabled by a GDD enabling STA shall not transmit, except to perform GDD enablement with a GDD enabling STA transmitting the GDD enabling signal.

A GDD dependent STA shall not transmit any frames other than GDD enablement-related frames and authentication and association frames before it performs the following GDD enablement procedure:

- The GDD dependent STA changes its GDD enablement state variable to *AttemptingGDDEnablement* after receiving a GDD enabling signal.
- After authentication and association, the GDD dependent STA securely sends a GDD Enablement Request frame to a GDD enabling STA from which it has received a GDD enabling signal. Based on the input received from the GDD dependent STA, the GDD enabling STA responds with a GDD Enablement Response frame indicating the result for the enablement request.
- When a GDD dependent STA receives a GDD Enablement Response frame with the Status Code SUCCESS within *dot11GDDEnablementTimeLimit*, the GDD enablement state variable of the GDD dependent STA is set to *GDDEnabled*. Once it becomes enabled, the GDD dependent STA maintains a GDD enablement validity timer, which is initialized to *dot11ContactVerificationSignalInterval*.

A GDD dependent STA that has not attained GDD enablement from a GDD enabling STA shall not transmit beyond `dot11GDDEnablementTimeLimit`, measured from the time of the first `PHY-TXSTART.request` primitive, while attempting to attain GDD enablement. Then, when the GDD enablement attempt fails within the allowed maximum time, it shall not transmit for `dot11GDDEnablementFailHoldTime`, before it may again attempt to attain GDD enablement.

NOTE—A GDD dependent STA might detect several GDD enabling STAs. If the GDD dependent STA is unable to obtain a GDD Enablement Response frame from one GDD enabling STA, it might make further attempts with additional GDD enabling STAs within the maximum time limit of `dot11GDDEnablementTimeLimit`.

Once in *GDDEnabled* state, the following rules apply to a GDD dependent STA during its operations:

- The GDD dependent STA shall maintain a GDD enablement validity timer by decrementing `dot11GDDEnablementValidityTimer`. The procedures for maintaining the GDD enablement validity timer are defined in 11.44.9, 11.44.6, and 11.44.4.
- A GDD dependent STA shall cease all transmission when the `dot11GDDEnablementValidityTimer` has expired. It then changes its GDD enablement state to *Unenabled*.
- A GDD dependent STA shall immediately cease all transmission if it receives an unsolicited GDD Enablement Response frame with a Status Code of AUTHORIZATION DEENABLED from the GDD enabling STA that enabled its operation.

11.44.4 Channel availability query (CAQ) procedure

11.44.4.1 Introduction

This subclause describes a channel availability query procedure that can be used to obtain the list of available channels for the operation of a GDD STA. A STA shall not use the CAQ procedure specified here unless `dot11GDDActivated` is true.

A GDD dependent STA sends the channel availability query request to a GDD enabling STA to obtain the list of available channels. The CAQ procedure might be initiated by the GDD dependent STA in order to remain in the *GDDEnabled* state during its normal operational mode, as specified in 11.44.3.

The GDD dependent STA sends the Channel Availability Query frame to obtain the new channel availability information when it receives an indication of change in the available channel list for its use, such as from a recent CVS signal (see 11.44.6).

Once the GDD dependent STA successfully receives the response for its Channel Availability Query frame from the GDD enabling STA, it reinitializes the `dot11GDDEnablementValidityTimer` to `dot11ContactVerificationSignalInterval`.

A GDD STA that acquires its geolocation position with the accuracy required by the regulatory domain sets `dot11GeolocationCapabilityActivated` to true. Any STA that operates as a GDD enabling STA might have its geolocation position before it initiates the CAQ procedure. Such a STA might transmit a channel availability query request to another GDD enabling STA. The responding STA generates the CAQ response after communicating to the RLSS, if the Channel Availability Query frame was received in a Channel Availability Query RLQP-element.

NOTE—A GDD enabling STA can send the Channel Availability Query frame to another GDD enabling STA. The responding GDD enabling STA, in such a case, can contact a GDB with the location and identifying parameters sent by the requesting STA.

A GDD enabling STA performs the CAQ procedure to update its channel availability when it determines that its geolocation position has moved beyond the permitted distance or beyond the validity time since its last query, as required by regulation.

STAs might transmit a channel availability query request in the protected dual of a CAQ Public Action frame (see 9.6.8.25, or in a GAS Initial Request frame containing an Channel Availability Query RLQP-element (see 9.4.6.2).

The procedures for channel availability query requesting STA and channel availability query responding STA are specified in 11.44.4.2 and 11.44.4.3.

In some regulatory domains, CAQ procedures may be conducted in other bands with properly implemented security to meet regulatory requirements. In such cases, CAQ RLQP rather than CAQ protected duals of Public Action frames shall be used.

11.44.4.2 CAQ requesting STA

A GDD dependent STA or a GDD enabling STA may initiate a CAQ procedure as a CAQ requesting STA.

A CAQ requesting STA may use RLQP to transmit a CAQ request when it detects RLQP support by its intended CAQ responder in a Beacon or Probe Response frame and to transmit a CAQ request to a STA with which it is associated when the requesting STA detects RLQP support.

Upon receipt of the MLME-GAS.request primitive with an AdvertisementProtocolID value of RLQP and Query parameters with the values of the fields in the RLQP Channel Availability Query element, the requesting STA performs the procedure specified in 11.25.3.2.2 to transmit a GAS Initial Request frame that contains the Channel Availability Query RLQP-element. The specific information items in the Query Request field of the GAS Initial Request frame are defined in 9.4.6.2.

The CAQ requesting STA may send the protected dual of a Channel Availability Query frame where the CAQ responding STA does not support RLQP capability. Upon receipt of the MLME-CHANNELAVAILABILITYQUERY.request primitive with Reason Result Code of 1, the MLME schedules for transmission a Channel Availability Query frame. The specific information items in the protected dual of a CAQ Public Action are defined in 9.6.8.25.

The CAQ requesting STA sets the Reason Result Code field to 1 and provides the Query Info field, as shown in Figure 9-631, to indicate if the Device Identification or Location Information fields are included in the Channel Availability Query frame.

A GDD enabling STA sending the Channel Availability Query frame should provide its device identification information in a format specified in 9.4.4.2.2.

A GDD enabling STA with dot11GeolocationCapabilityActivated equal to true should provide one or more Location Information fields in its Channel Availability Query frame.

A CAQ requesting STA may request a common channel list applicable to a bounded geographic area by providing more than one Device Location Information field in the Channel Availability Query frame. The bounded geographic area is defined by the area surrounded by the given sets of geographic coordinates in the multiple Device Location Information fields.

11.44.4.3 CAQ responding STA

A GDD enabling STA that receives the Channel Availability Query frame performs the role of the CAQ responding STA.

When a GDD enabling STA that has dot11RLSSActivated true receives a Channel Availability Query RLQP-element request, it generates and transmits the Channel Availability Query RLQP-element response to the requesting STA. Upon receipt of the MLME-GAS.response primitive with ResponseInfo parameter having a value of the corresponding field in the CAQ element, the responding STA transmits a Channel Availability Query RLQP-element response.

The CAQ responding STA generates the response to the CAQ requesting STA based on the result obtained from the RLSS. The specific information items in the Channel Availability Query RLQP-element response are defined in 9.4.6.2 and are set as follows:

- Requester STA Address field set to the MAC address of the STA from which the query was received.
- If no security method is enabled on the connection between the CAQ requesting STA and the CAQ responding STA, the Reason Result Code field is set to 4 (REFUSED).
- Reason Result Code field set to 2 or 3 for successful result or to 4 or 5 for failure, as defined in 9.4.6.2.
- WSM Information field, as defined in 9.4.4.2.5 when the Reason Result Code is set to 2 or 3.

NOTE—For the CAQ process, the RLSS provides the list of available channels for the location(s) provided by the requesting STA in the Query Response. In some regulatory domains, the RLSS can perform access to a GDB to derive its response for channel query request and the associated information it provides in its Query Response.

A CAQ responding STA might receive a Channel Availability Query frame or its protected dual. Upon receipt of the MLME-CHANNELAVAILABILITYQUERY.response primitive, the MLME schedules for transmission of the response in a Channel Availability Query frame. The Channel Availability Query frame or its protected dual is generated based on the ResultCode and other parameters received from the SME for the Channel Availability Query frame, as follows:

- Requester STA Address field set to the value of the PeerSTAAddress parameter.
- If no security method is enabled on the connection between the CAQ framing STA and the CAQ responding STA, the Reason Result Code field is set to 4 (REFUSED).
- Reason Result Code field set to 2 or 3 for successful result or to 4 or 5 for failure, as defined in 9.4.6.2.
- WSM Information field, as defined in 9.4.4.2.5 when the Reason Result Code is set to 2 or 3.

When a CAQ Responding STA receives the Channel Availability Query frame from a GDD dependent STA, it sets the Reason Result Code field to 2 when the query is successful and provides the WSM information it has obtained for its own location.

When a CAQ Responding STA receives the Channel Availability Query frame from another GDD enabling STA that includes one or more Device Location Information fields in the Channel Availability Query frame, it sets the Reason Result Code field to 2 or 3 when the query is successful and provides the WSM information that is valid for the location of the requesting STA.

When the Channel Availability Query frame contains multiple Device Location Information fields, the WSM information in the CAQ response is applicable for any location within the bounded area defined by the multiple locations. When the Channel Availability Query frame contains two Device Location Information fields, the WSM information in the CAQ response is applicable for any location within the bounded area determined by the uncertainty values of the coordinates of the second Device Location Information field. If no common channels are available to the bounded geographic area defined by multiple locations, CAQ responding STA responds with Reason Result Code field set to 2 (Success with the available

channel list result for Device Location Information field) and WSM information applicable to the first Device Location Information field in the Channel Availability Query frame. If one or more common channels are available to the bounded geographic area defined by multiple locations, the CAQ responding STA responds with Reason Result Code field set to 3 (Success with an available channel list result for a bounded geographic area defined by multiple Device Location Information fields) and a corresponding WSM Information field.

When a CAQ responding STA receives the protected Channel Availability Query frame, the response shall be sent using the protected Channel Availability Query frame.

11.44.5 Channel schedule management (CSM) procedures

11.44.5.1 Introduction

This subclause describes a channel schedule management procedure that can be used to obtain the list of available channels for the operation of a GDD STA. STAs can use the CSM procedure specified here when dot11GDDActivated is true.

Upon receipt of MLME-CHANNELSCHEDULEMANAGEMENT.request primitive, the MLME schedules transmission for a CSM request frame. If the parameter Protected of the MLME-CHANNELSCHEDULEMANAGEMENT.request primitive has the value true, then the CSM request frame as defined in 9.6.8.26 is transmitted in a Protected Dual of Public Action frame; otherwise the CSM request frame is transmitted in a Public Action frame.

Upon receipt of MLME-GAS.request primitive with an AdvertisementProtocolID parameter value of RLQP and Query parameter for a Channel Schedule Management RLQP-element, the requesting STA performs the procedure specified in 11.25.3.2.2 to transmit a GAS Initial Request frame that contains the Channel Schedule Management RLQP-element.

A GDD enabling STA transmits a CSM request to a RLSS to query the schedule information on TV channels. By default, a RLSS is able to provide channel schedule information on TV channels. However, the RLSS may reject the request by responding with Reason Result Code field set to the value for “Request declined by RLSS for unspecified reason.”

A GDD enabling STA transmits a CSM request to a RLSS to query the schedule information on WLAN channels. The RLSS maps channel schedule information from TV channels to WLAN channels and provides the schedule information, as defined in 9.4.4.2.4, to the GDD enabling STA that sent the query to facilitate WLAN operation. A RLSS that is not capable of providing WLAN channel schedule information responds to a request using the CSM response with the Reason Result Code field set to the value for “Request declined by RLSS because of no capability for providing schedule information on WLAN channels.”

A GDD enabling STA transmits a CSM request to another GDD enabling STA that is capable of database access as indicated in the GDD enabling signal. The GDD enabling STA that is capable of database access is able to access the RLSS and obtain the channel schedule information on TV channels. The GDD enabling STA may respond to a request by sending the CSM response with Reason Result Code field set to the value for “Request Declined by the GDD enabling STA because of no capability for providing schedule information on WLAN channels.”

A GDD enabling STA may transmit a CSM request to query WLAN channel information from another GDD enabling STA. A GDD enabling STA responds to a CSM request using a CSM response with the Reason Result Code field set to the value for “Success” if it is capable of providing channel schedule information on WLAN channels obtained from a RLSS and responds with the Reason Result Code field set

to the value for “Request declined by the GDD enabling STA because of no capability for providing schedule information on WLAN channels,” otherwise.

When the information in a CSM response is identical to the information in the most recently transmitted CSM response to the same requesting STA, the responding STA can set the Reason Result Code field value CSM element in a query response to “Successful” with no channel schedule changes from the last query of the RLSS and omit both the Channel Schedule Management Mode and Channel Schedule Descriptor fields.

A GDD enabling STA with dot11ChannelScheduleManagementActivated true may send a CSM frame to update the channel schedule information of another GDD enabling STA that receives an available channel list from it.

The GDD dependent STA shall not transmit a CSM request.

The details of requesting and responding with CSM are provided in 11.44.5.2 and 11.44.5.3.

11.44.5.2 CSM requesting STA

A STA employing RLQP uses the GAS protocol for its CSM procedure with a RLSS. Upon receipt of the MLME-GAS.request primitive with an AdvertisementProtocolID value of RLQP and Query parameter with the value of Channel Schedule Management RLQP-element, the CSM requesting STA transmits an RLQP-element with RLQP ID for CSM in the Query Request field in a GAS Initial Request frame. The specific information items in the Query Request field of the GAS Initial Request frame are generated as follows:

- Reason Result Code field = 0 or 1 as defined in 9.6.8.26.
- Channel Schedule Management Mode field = 0 or 1 as defined in 9.6.8.26.
- Channel Schedule Descriptor field, as defined in 9.4.4.2.4, containing the channel that the STA wants to query.

A STA uses the CSM Public Action frame or its protected dual to query another STA for channel schedule information. Upon receipt of the MLME-CHANNELSCHEDULEMANAGEMENT.request primitive with the CSM parameter of CSM element, the requesting STA transmits a CSM frame. The request frame is generated as follows:

- Reason Result Code field = 0 or 1 as defined in 9.6.8.26.
- Channel Schedule Management Mode field = 0 or 1 as defined in 9.6.8.26.
- Channel Schedule Descriptor field, as defined in 9.4.4.2.4, contains only the channel that the STA wants to query.

11.44.5.3 CSM responding STA

A STA employing RLQP uses the GAS protocol for its CSM procedure with a RLSS. Upon receipt of the MLME-GAS.request primitive with an ResponseInfo parameter value of Channel Schedule Management RLQP-element, the CSM responding STA transmits a RLQP-element with RLQP ID for CSM in the Query Response field in a GAS Initial Response frame or one or more GAS Comeback Response frames. The responding RLQP CSM shall be transmitted in a Protected Dual of Public Action frame if the received CSM is protected. The specific information items in the Query Response field of the GAS Initial Response frame are generated as follows:

- Reason Result Code field = values 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12 as defined in 9.6.8.26.
- Channel Schedule Descriptor field, as defined in 9.4.4.2.4, contains the channel and related channel schedule information.

A STA uses CSM Public Action frame or its protected dual to respond to another STA with channel schedule information. Upon receipt of the MLME-CHANNELSCHEDULEMANAGEMENT.request primitive with CSM parameter value of CSM element, the CSM responding STA transmits a CSM frame in response. The responding CSM shall be transmitted in a Protected Dual of Public Action frame if the received CSM is protected. The CSM response frame is generated as follows:

- Reason result code field = values 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, or 12 as defined in 9.6.8.26.
- Channel Schedule Descriptor field, as defined in 9.4.4.2.4, contains the channel and related channel schedule information.

11.44.6 Contact verification signal (CVS)

The Contact Verification Signal frame is transmitted by a GDD enabling STA to establish that its GDD dependent STAs are within the reception range of the GDD enabling STA and to validate the available channel list. A GDD enabling STA with dot11ContactVerificationSignalActivated true shall transmit an individually addressed Protected CVS frame (see 9.6.8.27) to its GDD dependent STAs.

A GDD dependent STA receives a CVS frame transmitted from its GDD enabling STA that provided the WSMs to verify that it is within reception range of that GDD enabling STA. The CVS frame has a Map ID field that indicates whether the WSM has been changed. A GDD dependent STA compares values of the Map ID field in the CVS frame with the Map ID of its existing WSM. If they are the same, then the GDD dependent STA assumes that its WSM is valid, and it sets dot11GDDEnablementValidTimer equal to dot11ContactVerificationSignalInterval. If they are different, the WSM is invalid because WSM information has changed. The STA should transmit a Channel Availability Query frame and receive a response in a Channel Availability Query frame that contains an updated WSM. If the GDD dependent STA fails to retrieve the updated WSM, it shall change its GDD enablement state to *unenabled* and stop transmitting over the air after dot11GDDEnablementValidTimer has expired.

11.44.7 Network channel control (NCC) procedures

11.44.7.1 Introduction

This subclause describes network channel control procedures that can be used to manage channels for operation of a GDD STA. A STA may use the NCC procedures specified here when dot11GDDActivated is true.

Network channel control utilizes a two-message transaction sequence to allow an NCC responding STA to control the frequency usage in TV bands of an NCC requesting STA's WLAN network channels. The first MMPDU sent by the NCC requesting STA asserts identity and requests NCC information. The NCC requesting STA may select its preferred frequencies from its WSM and request usage. The MMPDU sent by the NCC responding STA returns the NCC result. The NCC responding STA might grant permission to use the selected frequencies for multiple WLAN network channels to the NCC requesting STA by responding with a Network Channel Control frame (see 9.6.8.30). When responding, the NCC responding STA provides the confirmed WLAN network channels and the transmit power constraints as well. The WLAN network channels that the NCC responding STA confirms might be the same as or a subset of the network channels listed in the Network Channel Control frame received from the NCC requesting STA.

An NCC requesting STA employing RLQP may send an Network Channel Control frame to the RLSS to request its preferred frequencies given by the WSM for WLAN network channels. The NCC requesting STA accomplishes this by transmitting an RLQP-element with the RLQP ID for NCC in the Query Request field in a GAS Initial Request frame. After it receives this frame the NCC responding STA forwards the NCC request to the RLSS. After receiving the NCC request, the RLSS responds and sends an NCC response via

the NCC responding STA to the NCC requesting STA. When responding, the RLSS also provides the confirmed WLAN network channels and the transmit power constraints. The WLAN network channels that the RLSS confirms might be the same as or a subset of the network channels listed in the Network Channel Control request frame received from the NCC requesting STA.

Whenever the WSM has changed due to the update of the database information or detection of the primary service signals, an NCC requesting STAs may transmit a new Network Channel Control frame.

11.44.7.2 NCC requesting STA

An NCC requesting STA may be a GDD dependent STA. An NCC requesting STA employing RLQP may use the GAS protocol for its NCC procedure with a RLSS. Upon receipt of the MLME-GAS.request primitive with an AdvertisementProtocolID value of RLQP and Query parameter with the value of Network Channel Control RLQP-element, the NCC requesting STA transmits an RLQP-element with Info ID for NCC in the Query Request field in a GAS Initial Request frame. The specific information items in the Query Request field of the GAS Initial Request frame are generated as follows:

- The Requester STA Address field is set to the MAC address of the NCC requesting STA.
- The Responder STA Address field is set to the MAC address of the NCC responding STA.
- The Reason Result code is REQUEST, as defined in 9.4.6.4.
- The Number of Network Channel Control Triplets field, as defined in 9.4.6.4, gives the number of triplets of Operating Class, Channel Number, and Transmit Power Constraint fields.
- The Operating Class and Channel Number fields, with the values defined in E.1, together specify the channel frequency and channel bandwidth for WLAN network channels selected by the NCC requesting STA.
- The Maximum Transmit Power field, as defined in 9.4.6.4, is set to the intended maximum transmit power in dBm for operation of the requesting STA.

An NCC Requesting STA might use the Network Channel Control frame or its protected dual to query another STA to request frequency usage in TV bands for WLAN network channels. Upon receipt of the MLME-NETWORKCHANNELCONTROL.request primitive, the requesting STA transmits a (protected) Network Channel Control frame. The request frame is generated as follows:

- The Requester STA Address field is set to the MAC address of the NCC requesting STA.
- The Responder STA Address field is set to the MAC address of the NCC responding STA.
- The Reason Result Code is REQUEST, as defined in 9.4.6.4.
- The Number of Network Channel Control Triplets field, as defined in 9.4.6.4, gives the number of triplets of Operating Class, Channel Number, and Transmit Power Constraint fields.
- The Operating Class and Channel Number fields, with the values defined in E.1, together specify the channel frequency and channel bandwidth for WLAN network channels selected by the NCC requesting STA.
- The Maximum Transmit Power field, as defined in 9.4.6.4, is set to the intended maximum transmit power in dBm for operation of the requesting STA.

11.44.7.3 NCC responding STA

An NCC responding STA may be a GDD enabling STA. An NCC responding STA employing RLQP may use the GAS protocol for its NCC procedure with a RLSS. Upon receipt of the MLME-GAS.response primitive with a ResponseInfo parameter value of Network Channel Control RLQP-element, the NCC responding STA transmits a RLQP-element with Info ID for NCC in the Query Response field in a GAS Initial Response frame or one or more GAS Comeback Response frames. The specific information items in the Query Response field of the GAS Initial Response frame are generated as follows:

- Requester STA Address field set to the MAC address of the NCC requesting STA.
- Responder STA Address field set to the MAC address of the NCC responding STA.
- Reason Result Code field = values SUCCESS, REFUSED, TOO_MANY_SIMULTANEOUS_REQUESTS, or Continuation frame as defined in 9.4.6.4.
- The Number of Network Channel Control Triplets field, as defined in 9.4.6.4, gives the number of triplets of Operating Class, Channel Number, and Transmit Power Constraint fields.
- The Operating Class and Channel Number fields, with the values defined in E.1, together specify the channel frequency and channel bandwidth that the NCC responding STA has granted permission to the NCC requesting STA for WLAN operation.
- The Maximum Transmit Power field, as defined in 9.4.6.4, sets to maximum allowable transmit power in dBm of the requesting STA’s WLAN operation.

An NCC responding STA may use an Network Channel Control frame or its protected dual to respond to another STA with NCC information. Upon receipt of the MLME-NETWORKCHANNELCONTROL.response primitive with NCC parameter value of NCC element, the NCC responding STA transmits a Network Channel Control frame containing an NCC element. The response frame is generated as follows:

- Requester STA Address field set to the MAC address of the NCC requesting STA.
- Responder STA Address field set to the MAC address of the NCC responding STA.
- Reason Result Code = values SUCCESS, REFUSED, TOO_MANY_SIMULTANEOUS_REQUESTS, or Continuation frame as defined in 9.4.6.4.
- The Number of Network Channel Control Triplets field, as defined in 9.4.6.4, gives the number of triplets of Operating Class, Channel Number, and Transmit Power Constraint fields.
- The Operating Class and Channel Number fields, with the values defined in E.1, together specify the channel frequency and channel bandwidth that the NCC responding STA has granted permission to the NCC requesting STA for WLAN operation.
- The Maximum Transmit Power field, as defined in 9.4.6.4, sets to maximum allowable transmit power in dBm of the requesting STA’s WLAN operation.

11.44.8 Reduced neighbor report

In Beacon and Probe Response frames, a Reduced Neighbor Report element may be transmitted by an AP with dot11TVHTOptionImplemented true. A Reduced Neighbor Report element contains information on neighbor APs. A Reduced Neighbor Report element might not be exhaustive either by choice or by the fact that there may be neighbor APs not known to the AP.

The Reduced Neighbor Report element contains a list of operating classes and primary channels along with TBTT information for the reported neighbor APs on each operating class and primary channel. The operating class is selected from values in Table E-4 filtered by the requirement that, together with the Channel Number field, the primary channel be identifiable.

NOTE—For instance, this excludes operating class 128–130.

When the reporting AP cannot obtain an operating class that, together with the Channel Number field, identifies the primary channel from the neighboring AP, then the reporting AP shall report an operating class that, together with a channel number, identifies the primary channel of the reported BSS. Given a choice of operating classes that preserve the identification of the primary channel, the reporting AP should select an operating class that preserves as many behavior limits as possible known to the reporting AP.

NOTE—An operating class might be unavailable because the neighboring AP does not transmit an operating class or the transmitted operating class does not indicate a primary channel.

A Reduced Neighbor Report element includes only channels that are consistent with the Country element in the frame in which the Reduced Neighbor Report element appears. The Reduced Neighbor Report element contents may be derived from the NeighborListSet parameter of the MLME-NEIGHBORREPRES.request primitive. The contents of the Reduced Neighbor Report element might also be configured or obtained by other means beyond the scope of this standard.

If the Supported Operating Classes element of the STA is included in the Probe Request frame, the reduced neighbor report contains information on neighbor APs whose current operating class matches the supported operating classes in the Probe Request frame.

The Reduced Neighbor Report element shall include the information on neighbor APs whose SSID matches the specific SSID in the Probe Request frame if the Filtered Neighbor AP bit in the Neighbor AP Information field is set to 1.

A serving AP shall include a value less than 255 in the Neighbor AP TBTT Offset subfield if it is able to guarantee an accumulated error of 1.5 TU or better.

A STA receiving a Reduced Neighbor Report element may use the report to schedule passive scanning for faster AP discovery. The scheduling process is beyond the scope of this standard. A STA receiving a Reduced Neighbor Report element with an unknown subelement identifier shall ignore the unknown subelement and continue to process the remaining subelements.

11.44.9 White space map (WSM)

This subclause describes WSM procedures that can be used to obtain lists of available channels for operation of a GDD STA. STAs can use the WSM procedure specified here when dot11GDDActivated is true.

When dot11WhiteSpaceMapActivated is true, a GDD STA shall follow the procedures in this subclause.

If dot11WhiteSpaceMapActivated is true, a GDD enabling STA transmits a WSM, and a GDD dependent STA can transmit frames only on the available channels indicated in its valid WSM. GDBs can be different according to each regulatory domain and its regulatory requirements. A WSM Type field value of 1 indicates that the WSM is generated from the GDB and the WSM Information field of the WSM element specifies the available information for TVWS, which is country-specific and defined in 9.4.4.2.5.

A GDD enabling STA contacts a GDB to obtain the permissible frequencies and operating parameters before it begins its transmissions. After receiving the WSM information from a GDB, a GDD enabling STA operates in TVWS only in the frequencies that the GDB indicates are available. The GDD enabling STA generates WSMs based on the information from the GDB. It may update WSMs when STAs perform a measurement or receive a measurement report in which a primary service signal is measured on a channel, which is indicated as available from the GDB.

A WSM element includes a list of identified available channels and corresponding maximum allowed transmission powers for each available channel.

When a GDD enabling STA retrieves updated available frequency information, it is able to transmit individually addressed Protected WSM Announcement frames with an updated WSM element to its GDD dependent STAs.

A GDD dependent STA receiving a WSM element operates on the channels indicated in the WSM. A GDD dependent STA that receives an updated WSM from its GDD enabling STA shall move its channel of operation if it is operating on a channel that has become unavailable in the updated WSM.

A GDD enabling STA transmits a WSM within a GDD Enablement Response frame, CAQ response frame, and WSM Announcement frame. A Device Class field of a WSM in a GDD Enablement Response frame and CAQ response frame is set to a value of a Device Class field in a GDD Enablement Request frame and Channel Availability Query frame, respectively. A Device Class field of WSM in a WSM Announcement frame is set to a value of the Device Class field of a WSM in a GDD Enablement Request frame.

The value of the Map version bits in the Map ID field is increased by 1 (modulo 127) whenever the GDD enabling STA transmits the updated WSM. The most recently received WSM is used by the WSM receiving STAs. A WSM with a Map version value of 127 indicates that the WSM is informative and it does not affect the GDD enablement states of a GDD dependent STA. If the Type bit in the Map ID field is set to 1, the following channel list is a full channel list; and if the Type bit is set to 0, the following channel list is a partial channel list. If a STA receives several WSMs with the same Map version and the Type bit is equal to 0, the STA should construct the whole channel list using the multiple WSMs having the same Map version.

GDD dependent STAs receiving a WSM should scan for existing BSSs on the available channels identified within received WSM element. In TVWS a GDD dependent STA receiving a WSM element shall operate on the channels indicated in the WSM. A GDD dependent STA that has previously received a WSM and that receives an updated WSM from its AP or GDD enabling STA shall move its channel of operation if it is operating on a channel that has become unavailable in the updated WSM.

If dot11WhiteSpaceMapActivated is true, then the enabled GDD dependent STA may send a Probe Request frame on any channel identified in the received WSM element. An AP that has dot11WhiteSpaceMapActivated true and that receives a Probe Request frame should respond with a Probe Response frame containing a WSM element.

11.45 Beacon RSSI

Upon receiving a Beacon frame, a STA measures the received signal strength of the Beacon frame (dot11BeaconRssi). If the Beacon frame is received using multiple receive chains, the Beacon RSSI is averaged in linear domain over all active receive chains. The Beacon RSSI is reported in dBm. When operating in frequency bands below 6 GHz, the Beacon RSSI has an accuracy of ± 5 dB (95% confidence interval) within the specified dynamic range of the receiver. Beacon RSSI may be averaged over time using a vendor specific smoothing function.

11.46 Estimated throughput

A STA that has a value of true for dot11EstimatedServiceParametersOptionImplemented is an estimated service parameters (ESP) STA.

Entities outside the scope of this standard that might control the traffic steering decision of a device benefit by being able to predict the throughput that might be obtained through a link with a STA. Those same entities also need to know what the current estimate of throughput is for network selection purposes (by comparing an estimated throughput with existing throughput). The MLME-ESTIMATED-THROUGHPUT.request and MLME-ESTIMATED-THROUGHPUT.confirm primitives together provide an interface to allow such entities, operating through the SME, to obtain an estimate of throughput for MSDUs sent between the STA that corresponds to the PeerMACAddress indicated in the parameter list of the MLME-ESTIMATED-THROUGHPUT.request primitive and this STA.

When an MLME-ESTIMATED-THROUGHPUT.request primitive is received at the MLME, the MLME can use the parameters provided in the primitive plus the following information to create estimates of throughput per access category to deliver to the SME in the EstimatedThroughputOutbound parameter of the MLME-ESTIMATED-THROUGHPUT.confirm primitive:

- RSSI measured during reception of Beacon or Probe Response frames transmitted by the STA that corresponds to the MAC entity with the MAC address equal to the PeerMACAddress in the MLME-ESTIMATED-THROUGHPUT.request primitive to this STA
- Number of spatial streams that is expected to be supported on the link between this STA and the STA
- Channel bandwidth
- Estimated air fractional time
- Block ack window size

If the MLME is incapable of determining a value for the EstimatedThroughputOutbound or EstimatedThroughputInbound parameter for any access category, then the MLME shall return a value of 0 for the value of that parameter for that access category in the MLME-ESTIMATED-THROUGHPUT.confirm primitive. If the AverageMSDUSizeOutbound parameter for an access category is equal to -1 in the MLME-ESTIMATED-THROUGHPUT.request primitive, the STA shall include a value of 0 in the EstimatedThroughputOutbound parameter for the corresponding access category in the MLME-ESTIMATED-THROUGHPUT.confirm primitive. If the AverageMSDUSizeOutbound parameter for an access category is equal to 0 in the MLME-ESTIMATED-THROUGHPUT.request primitive, the STA may use any value for the average MSDU size used in calculating the estimated throughput to be included in the corresponding access category in the EstimatedThroughputOutbound parameter of the MLME-ESTIMATED-THROUGHPUT.confirm primitive, but should use a value of 1500 octets. If the AverageMSDUSizeInbound parameter for an access category is equal to -1 in the MLME-ESTIMATED-THROUGHPUT.request primitive, the STA shall include a value of 0 in the EstimatedThroughputInbound parameter for the corresponding access category in the MLME-ESTIMATED-THROUGHPUT.confirm primitive. If the AverageMSDUSizeInbound parameter for an access category is equal to 0 in the MLME-ESTIMATED-THROUGHPUT.request primitive, the STA may use any value for the average MSDU size used in calculating the estimated throughput to be included in the corresponding access category in the EstimatedThroughputInbound parameter of the MLME-ESTIMATED-THROUGHPUT.confirm primitive, but should use a value of 1500 octets.

An ESP STA should determine a value for EstimatedThroughputOutbound for each AC of a current or potential link with a STA using the equation found in R.7.

An ESP STA or a mesh STA may include a Request element that includes the element ID of the Estimated Service Parameters element in transmitted Probe Requests.

An ESP STA that is an AP or a mesh STA shall include the Estimated Service Parameters element within Probe Response frames transmitted in response to a Probe Request frame that included a Request element that includes the element ID of the Estimated Service Parameters element. An ESP STA that is not an AP may include the Estimated Service Parameters element within Probe Response frames transmitted in response to a Probe Request frame that included a Request element that includes the element ID of the Estimated Service Parameters element. An ESP STA may include the Estimated Service Parameters element within Probe Response frames transmitted in response to a Probe Request frame that did not include a Request element, or included a Request element that did not include the element ID of the Estimated Service Parameters element.

An ESP STA that is an AP or a mesh STA shall include the Estimated Service Parameters element within Beacon frames. An ESP STA that is not an AP may include the Estimated Service Parameters element within Beacon frames.

12. Security

12.1 Conventions

Reserved fields and subfields are set to 0 upon transmission and are ignored upon reception.

ASCII strings are defined in 9.2.2.

12.2 Framework

12.2.1 Classes of security algorithm

This standard defines two classes of security algorithms for IEEE 802.11 networks:

- Algorithms for creating and using an RSNA, called *RSNA algorithms*
- Pre-RSNA algorithms

NOTE—This standard does not prohibit STAs from simultaneously operating pre-RSNA and RSNA algorithms.

The use of WEP for confidentiality, authentication, or access control is deprecated. The WEP algorithm is unsuitable for the purposes of this standard.

The use of TKIP is deprecated. The TKIP algorithm is unsuitable for the purposes of this standard.

12.2.2 Security methods

Pre-RSNA security comprises the following algorithms and procedures:

- WEP, described in 12.3.2
- IEEE 802.11 entity authentication, described in 12.3.3

RSNA security comprises the following algorithms and procedures:

- TKIP, described in 12.5.2
- CCMP, described in 12.5.3
- GCMP, described in 12.5.5
- BIP, described in 12.5.4
- RSNA establishment and termination procedures, including use of IEEE 802.1X authentication, described in 12.6 and SAE authentication described in 12.4
- Key management procedures, described in 12.7

12.2.3 RSNA STA capabilities

When dot11RSNAActivated is true, an RSNA STA shall include the RSNE in Beacon, Probe Response, Information Response, and (Re)Association Request frames and in message 2 and message 3 of the 4-way handshake; shall set the DMG Privacy subfield to 1 within transmitted DMG Beacons; and may include the RSNE in DMG Beacon and Announce frames. A pre-RSNA STA is not capable of creating RSNAs.

All STAs implementing RSNA shall support the RSNE described in 9.4.2.25.

12.2.4 RSNA establishment

An SME establishes an RSNA in one of six ways:

- a) If an RSNA uses authentication negotiated over IEEE Std 802.1X in an infrastructure BSS, an RSNA-capable STA's SME establishes an RSNA as follows:
 - 1) It identifies the AP as RSNA-capable from the AP's Beacon, DMG Beacon, Announce, Information Response, or Probe Response frames.
 - 2) It shall invoke Open System authentication if the STA is a non-DMG STA.
 - 3) It negotiates cipher suites during the association process, as described in 12.6.2 and 12.6.3.
 - 4) It uses IEEE Std 802.1X-2010 to authenticate, as described in 12.6.10 and 12.6.11.
 - 5) It establishes one or more temporal keys by executing a key management algorithm, using the protocol defined by 12.7 or 13.
 - 6) It protects the data link by programming the negotiated cipher suites and the established temporal key into the MAC and then invoking protection. See, for example, 12.5.3 for a description of the RSNA data protection mechanisms.
 - 7) If the STAs negotiate management frame protection, the SME programs the TK and pairwise cipher suite into the MAC for protection of individually addressed robust Management frames. It also installs the IGTK and IPN for protection of group addressed robust Management frames.
- b) If an RSNA is based on a PSK or password in an infrastructure BSS, the SME establishes an RSNA as follows:
 - 1) It identifies the AP as RSNA-capable from the AP's Beacon, DMG Beacon, Announce, Information Response, or Probe Response frames.
 - 2) If the RSNA-capable AP advertises support for SAE authentication in its Beacon or Probe Response frames, and the STA has a group defined in the dot11RSNAConfigDLCGroupTable and a password for the AP in the dot11RSNAConfigPasswordValueTable, the STA shall invoke SAE authentication to establish a PMK. If the RSNA-capable AP does not advertise support for SAE authentication in its Beacon and Probe Response frames but advertises support for the alternate form of PSK authentication (see 4.10.3.4), and the STA also supports the alternate form of PSK authentication, the non-DMG STA may invoke Open System authentication and use the PSK as the PMK with the key management algorithm in step 4) below.
 - 3) It negotiates cipher suites during the association process, as described in 12.6.2 and 12.6.3.
 - 4) It establishes one or more temporal keys by executing a key management algorithm, using the protocol defined by 12.7.
 - 5) It protects the data link by programming the negotiated cipher suites and the established temporal key into the MAC and then invoking protection.
 - 6) If the STAs negotiate management frame protection, the STA programs the TK and pairwise cipher suite into the MAC for protection of individually addressed robust Management frames. It also installs the IGTK and IPN for protection of group addressed robust Management frames.
- c) If an RSNA is based on a PSK or password in an IBSS the SME executes the following sequence of procedures:
 - 1) It identifies the peer as RSNA-capable from the peer's Beacon, DMG Beacon, Announce, Information Response, or Probe Response frames.
 - 2) If the RSNA-capable peer advertises support for SAE authentication in its Beacon and Probe Response frames and the STA has a group defined in the dot11RSNAConfigDLCGroupTable and a password for the peer in the dot11RSNAConfigPasswordValueTable, the STA shall invoke SAE authentication and establish a PMK. If the RSNA-capable peer does not advertise support for SAE authentication but advertises support for the alternate form of PSK authentication (see 4.10.3.4), and the STA also supports the alternate form of PSK

NOTE—STAs might respond to a Data frame from an unrecognized STA by sending a Probe Request frame to find out whether the unrecognized STA is RSNA-capable.

- 2) If the RSNA-capable peer advertises support for SAE authentication in its Beacon and Probe Response frames and the STA has a group defined in the dot11RSNAConfigDLCGroupTable and a password for the peer in the dot11RSNAConfigPasswordValueTable, the STA shall invoke SAE authentication and establish a PMK. If the RSNA-capable peer does not advertise support for SAE authentication but advertises support for the alternate form of PSK authentication (see 4.10.3.4), and the STA also supports the alternate form of PSK

authentication the STA may invoke Open System authentication if the STA is a non-DMG STA and use a PSK as the PMK with the alternate form of PSK authentication.

- 3) Each STA uses the procedures in 12.7, to establish one or more temporal keys and to negotiate cipher suites. Note that two peer STAs might follow this procedure simultaneously. See 12.6.15.
- 4) It protects the data link by programming the negotiated cipher suites and the established temporal key and then invoking protection.
- d) If an RSNA uses authentication negotiated over IEEE Std 802.1X in an IBSS, an RSNA-capable STA's SME establishes an RSNA as follows:
 - 1) It identifies the peer as RSNA-capable from the peer's Beacon, DMG Beacon, Announce, Information Response, or Probe Response frames.

NOTE—STAs might respond to a Data frame from an unrecognized STA by sending a Probe Request frame to find out whether the unrecognized STA is RSNA-capable.

- 2) It may invoke Open System authentication if the STA is a non-DMG STA.
- 3) Each STA uses IEEE Std 802.1X-2010 to authenticate with the AS associated with the other STA's Authenticator, as described in 12.6.10 and 12.6.11.

NOTE—Two peer STAs might follow this procedure simultaneously.

- 4) Each SME establishes one or more temporal keys by executing a key management algorithm, using the protocol defined in 12.7. Hence two such key management algorithms are happening in parallel between any two STA's Suplicants and Authenticators.
- 5) Both STAs use the agreed-upon temporal key portion of the PTK and pairwise cipher suite from one of the exchanges to protect the link. Each STA uses the GTK established by the exchange it initiated to protect the group addressed frames it transmits.
- e) In order to associate with a PCP in a PBSS, an RSNA-capable STA's SME establishes an RSNA with the PCP following the RSNA establishment steps in an infrastructure BSS in accordance with method a) and b) above, as appropriate, with the PCP taking the role of the AP.
- f) When an RSNA-capable STA chooses not to associate with a peer in a PBSS, its SME establishes an RSNA with the peer following the RSNA establishment steps in an IBSS in accordance with method c) or d) above, as appropriate, with the caveat that the RSNA authentication and key management algorithm is executed only once between the peers.

The time a security association takes to set up shall be less than dot11RSNAConfigSATimeout. The security association setup starts when initiated by the SME and completes when the MLME-SETPROTECTION.request primitive is invoked. The action the STA takes on the timeout is a policy decision. Some options include retrying the security association setup or trying another STA. This timeout allows recovery when one of the STAs setting up a security association fails to respond correctly to setting up the security association. It also allows recovery in IBSS when one of the two security associations fails because of a security association timeout.

Only Authentication frames with the authentication algorithm equal to Open System authentication or FT authentication may be used within an RSNA. An RSNA STA shall not associate if Shared Key authentication was invoked prior to RSN association.

12.2.5 RSNA PeerKey Support

The STSL mechanism is obsolete. Consequently, the PeerKey protocol components that do not support the AP PeerKey protocol might be removed in a later revision of the standard.

The PeerKey protocol provides mutual authentication, session identification, and data confidentiality for a station-to-station connection. A PeerKey association, composed of an SMKSA and an STKSA, shall be allowed only within the context of an existing RSNA by both peers with a common AP, or between peer APs that implement the AP PeerKey protocol. An initiator STA or peer STA shall not initiate an STSL master key (SMK) handshake and STSL transient key (STK) handshake if dot11RSNAActivated is false. An initiator STA or peer STA shall not establish a security association if dot11RSNAActivated is false.

A STSL session may choose to allow unprotected communication between STAs. In this case, the PeerKey protocol is not used.

12.2.6 RSNA assumptions and constraints

An RSNA assumes the following:

- a) Each STA can generate cryptographic-quality random numbers. This assumption is fundamental, as cryptographic methods require a source of randomness. See J.5 for suggested hardware and software methods to achieve randomness suitable for this purpose.
- b) When IEEE 802.1X authentication is used, the specific EAP method used performs mutual authentication. This assumption is intrinsic to the design of RSN in IEEE 802.11 LANs and cannot be removed without exposing both the STAs to man-in-the-middle attacks. EAP-MD5 is an example of an EAP method that does not meet this constraint (see IETF RFC 3748 [B42]). Furthermore, the use of EAP authentication methods where server and client credentials are not differentiated reduces the security of the method to that of a PSK due to the fact that malicious insiders might masquerade as servers and establish a man-in-the-middle attack.

In particular, the mutual authentication requirement implies an unspecified prior enrollment process (e.g., a long-lived authentication key or establishment of trust through a third party such as a certification authority), as the STA needs to be able to identify the ESS or IBSS as a trustworthy entity and vice versa. The STA shares authentication credentials with the AS utilized by the selected AP or, in the case of PSK, the selected AP. The SSID provides an unprotected indication that the selected AP's authentication entity shares credentials with the STA. Only the successful completion of the IEEE 802.1X EAP or PSK authentication, after association, validates any such indication that the AP is connected to an authorized network or service provider.

- c) The mutual authentication method needs to be strong, meaning impersonation attacks are computationally infeasible when based on the information exposed by the authentication. This assumption is intrinsic to the design of RSN.
- d) The AP and AS have a trustworthy channel between them that can be used to exchange cryptographic keys without exposure to any intermediate parties.
- e) An IEEE 802.1X AS never exposes the common symmetric key to any party except the AP with which the STA is currently communicating. This is a very strong constraint. It implies that the AS itself is never compromised. It also implies that the IEEE 802.1X AS is embedded in the AP or that the AP is physically secure and the AS and the AP lie entirely within the same administrative domain. This assumption follows from the fact that if the AP and the AS are not collocated or do not share pairwise key encryption keys directly, then it is impossible to assure the non-AP STA that its key, which is distributed by the AS to the AP, has not been compromised prior to use.
- f) Similarly, a STA never shares with a third party a common symmetric key that it shares with a peer. Doing so destroys the utility of the key for detecting MPDU replay and forgery.
- g) The Supplicant and the Authenticator generate a different, fresh PTK for each session between the pair. This assumption is fundamental, as reuse of any PTK would enable compromise of all the data protected by that key.
- h) The destination STA chosen by the transmitter is the correct destination. For example, Address Resolution Protocol (ARP) and Internet Control Message Protocol (ICMP) are methods of determining the destination STA's MAC address that are not secure from attacks by other members

of the ESS. One of the possible solutions to this problem might be for the STA to send or receive only frames whose final DA or SA are the AP and for the AP to provide a network layer routing function. However, such solutions are outside the scope of this standard.

An HT STA shall not use either of the pairwise cipher suite selectors: “Use group cipher suite” or TKIP to communicate with another HT STA.

NOTE—Because a VHT STA is also an HT STA, the elimination of TKIP also applies to VHT STAs.

12.2.7 Requirements for the Protected Frame field

The Protected Frame field shall be set to 1 in:

- Data frames that are protected using the mechanisms specified in Clause 12.
- Individually addressed robust Management frames.
- Authentication frames with Authentication Algorithm Number field equal to 1 (Shared Key) and Authentication Transaction Sequence Number field equal to 3.

It shall be set to 0 in all other frames.

12.2.8 Requirements for robust management frame protection

The robust Management frames are Disassociation, Deauthentication, and robust Action frames.

Action frames specified with “No” in the “Robust” column of Table 9-47 are not robust Management frames and shall not be protected.

When management frame protection is negotiated, all group addressed robust Management frames shall be encapsulated using the procedures defined in 11.13.

12.2.9 Emergency service establishment in an RSN

An AP or mesh STA that supports RSNA and has the ESR bit set to 1 and the UESA bit set to 1 in the Interworking element in Beacon and Probe Response frames supports both RSNA and emergency services associations (see 11.3.5.2) simultaneously.

In an infrastructure BSS, the STAs with emergency services association should discard all group addressed frames they receive, as they do not possess the Group Key and therefore are not able to decrypt group addressed frames. In an RSNA enabled BSS that has one or more STAs associated with an emergency services association, an AP should avoid transmitting unprotected group addressed frames in order not to disturb the operation of STAs that are in possession of Group Key. One possible way of achieving this is to support Proxy-ARP in the AP, as defined in 11.24.14. In addition, it is recommended that an AP supporting emergency services association should also support DMS to convert group addressed frames to individually addressed frames and transmit them to STAs associated using the emergency services association. STAs using emergency services association might request DMS if needed.

12.3 Pre-RSNA security methods

12.3.1 Status of Pre-RSNA security methods

Except for Open System authentication, all pre-RSNA security mechanisms are obsolete. Support for them might be removed in a later revision of the standard.

Open System Authentication and Open System Deauthentication shall not be used between mesh STAs.

12.3.2 Wired equivalent privacy (WEP)

12.3.2.1 WEP overview

WEP-40 was defined as a means of protecting (using a 40-bit key) the confidentiality of data exchanged among authorized users of a WLAN from casual eavesdropping. Implementation of WEP is optional. The same algorithms have been widely used with a 104-bit key instead of a 40-bit key in fielded implementations; this is called *WEP-104*. The WEP cryptographic encapsulation and decapsulation mechanics are the same whether a 40-bit or a 104-bit key is used. The term WEP by itself refers to either WEP-40 or WEP-104.

12.3.2.2 WEP MPDU format

Figure 12-1 depicts the encrypted frame body as constructed by the WEP algorithm.

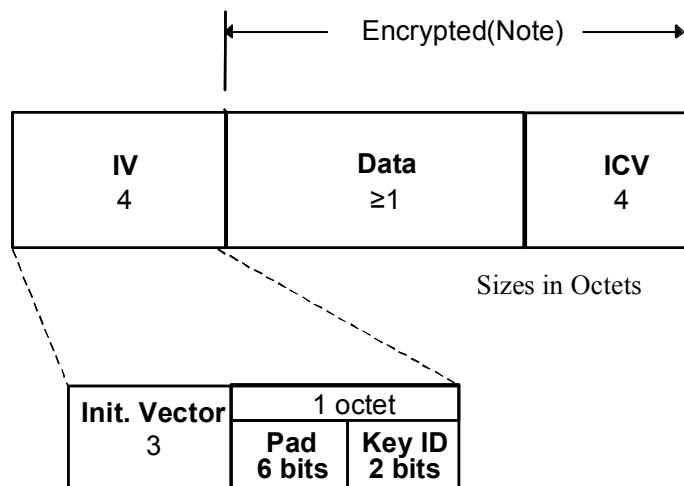

Figure 12-1—Construction of expanded WEP MPDU

The WEP ICV field shall be 32 bits in length. The expanded frame body shall start with a 32-bit IV field. This field shall contain three subfields: a 3-octet subfield that contains the IV, a 2-bit Key ID subfield, and a 6-bit Pad subfield. The ordering conventions defined in 9.2.2 apply to the IV field and its subfields and to the ICV field. The Key ID subfield contents select one of four possible secret key values for use in decrypting this frame body. When key-mapping keys are used, the Key ID field is reserved.

Interpretation of these bits is discussed further in 12.3.2.3. The contents of the Pad subfield shall be 0. The Key ID subfield occupies the 2 MSBs of the last octet of the IV field, while the Pad subfield occupies the 6 LSBs of this octet.

12.3.2.3 WEP state

WEP uses encryption keys only; it performs no data authentication. Therefore, it does not have data integrity keys. WEP uses two types of encryption keys: key-mapping keys and default keys.

A key-mapping key is an unnamed key corresponding to a distinct transmitter address-receiver address <TA,RA> pair. Implementations shall use the key-mapping key if it is configured for a <TA,RA> pair. In other words, the key-mapping key shall be used to WEP-encapsulate or -decapsulate MPDUs transmitted by TA to RA, regardless of the presence of other key types. When a key-mapping key for an address pair is present, the WEP Key ID subfield in the MPDU is reserved.

A default key is an item in a four-element MIB array called *dot11WEPDefaultKeys*, named by the value of a related array index called *dot11WEPDefaultKeyID*. If a key-mapping key is not configured for a WEP MPDU's <TA,RA> pair, WEP shall use a default key to encapsulate or decapsulate the MPDU. On transmit, the key selected is the element of the *dot11DefaultKeys* array given by the index *dot11WEPDefaultKeyID*—a value of 0, 1, 2, or 3—corresponding to the first, second, third, or fourth element, respectively, of *dot11WEPDefaultKeys*. The value the transmitter encodes in the WEP Key ID subfield of the transmitted MPDU shall be the *dot11WEPDefaultKeyID* value. The receiver shall use the Key ID subfield of the MPDU to index into *dot11WEPDefaultKeys* to obtain the correct default key. All WEP implementations shall support default keys.

NOTE—Many implementations also support 104-bit WEP keys. These are used exactly like 40-bit WEP keys: a 24-bit WEP IV is prepended to the 104-bit key to construct a 128-bit WEP seed, as explained in 12.3.2.4.3. The resulting 128-bit WEP seed is then consumed by the ARC4 stream cipher. This construction based on 104-bit keys affords no more assurance than the 40-bit construction, and its implementation and use are in no way condoned by this standard. Rather, the 104-bit construction is noted only to document de facto practice.

The default value for all WEP keys shall be null. WEP implementations shall discard the MSDU and generate an MA-UNITDATA-STATUS.indication primitive with transmission status indicating that a frame shall not be encapsulated with a null key in response to any request to encapsulate an MPDU with a null key.

12.3.2.4 WEP procedures

12.3.2.4.1 WEP ICV algorithm

The WEP ICV shall be computed using the CRC-32, as defined in 9.2.4.7, calculated over the plaintext MPDU Data (PDU) field.

12.3.2.4.2 WEP encryption algorithm

A WEP implementation shall use the ARC4 stream cipher from RSA Security, Inc., as its encryption and decryption algorithm. ARC4 uses a pseudorandom number generator (PRNG) to generate a key stream that it exclusive-ORs (XORs) with a plaintext data stream to produce cipher text or to recover plaintext from a cipher text.

12.3.2.4.3 WEP seed construction

A WEP implementation shall construct a per-MPDU key, called a *seed*, by concatenating an encryption key to an IV.

For WEP-40, bits 0–39 of the WEP key correspond to bits 24–63 of the seed, and bits 0–23 of the IV correspond to bits 0–23 of the seed, respectively. The bit numbering conventions in 9.2.2 apply to the seed. The seed shall be the input to ARC4, in order to encrypt or decrypt the WEP Data and ICV fields.

NOTE—For WEP-104, bits 0–103 of the WEP key correspond to bits 24–127 of the seed, and bit 0–23 of the IV correspond to bits 0–23 of the seed, respectively.

The WEP implementation encapsulating an MPDU's plaintext data should select a new IV for every MPDU it WEP-protects. The IV selection algorithm is unspecified. The algorithm used to select the encryption key used to construct the seed is also unspecified.

The WEP implementation decapsulating an MPDU shall use the IV from the received MPDU's Init Vector subfield. See 12.3.2.4.5 for the specification of how the decapsulator selects the key to use to construct the per-MPDU key.

12.3.2.4.4 WEP MPDU cryptographic encapsulation

WEP shall apply three transformations to the plaintext MPDU to effect the WEP cryptographic encapsulation. WEP computes the ICV over the plaintext data and appends this after the MPDU data. WEP encrypts the MPDU plaintext data and ICV using ARC4 with a seed constructed as specified in 12.3.2.4.3. WEP encodes the IV and key identifier into the IV field, prepended to the encrypted Data field.

Figure 12-2 depicts the WEP cryptographic encapsulation process. The ICV shall be computed and appended to the plaintext data prior to encryption, but the IV encoding step may occur in any order convenient for the implementation.

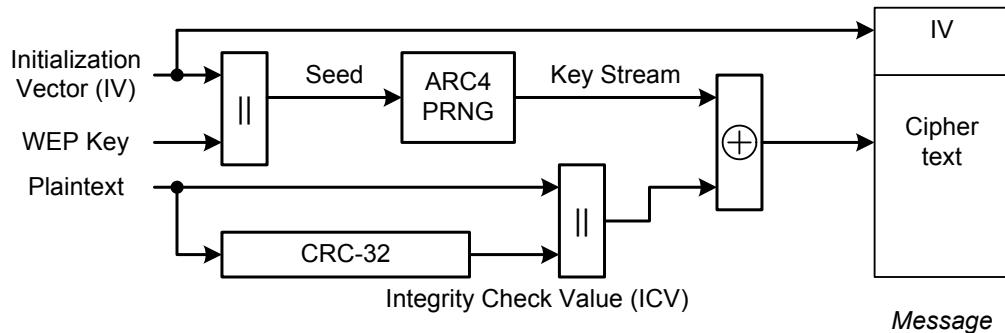

Figure 12-2—WEP encapsulation block diagram

12.3.2.4.5 WEP MPDU decapsulation

WEP shall apply three transformations to the WEP MPDU to decapsulate its payload. WEP extracts the IV and key identifier from the received MPDU. If a key-mapping key is present for the <TA,RA> pair, then this shall be used as the WEP key. Otherwise, the key identifier is extracted from the Key ID subfield of the WEP IV field in the received MPDU, identifying the default key to use.

WEP uses the constructed seed to decrypt the Data field of the WEP MPDU; this produces plaintext data and an ICV. Finally WEP recomputes the ICV and bitwise compares it with the decrypted ICV from the MPDU. If the two are bitwise identical, then WEP removes the IV and ICV from the MPDU, which is accepted as valid. If they differ in any bit position, WEP generates an error indication to MAC management. MSDUs with erroneous MPDUs (due to inability to decrypt) shall not be passed to LLC.

Figure 12-3 depicts a block diagram for WEP decapsulation. Unlike cryptographic encapsulation, the decapsulation steps shall be in the indicated order.

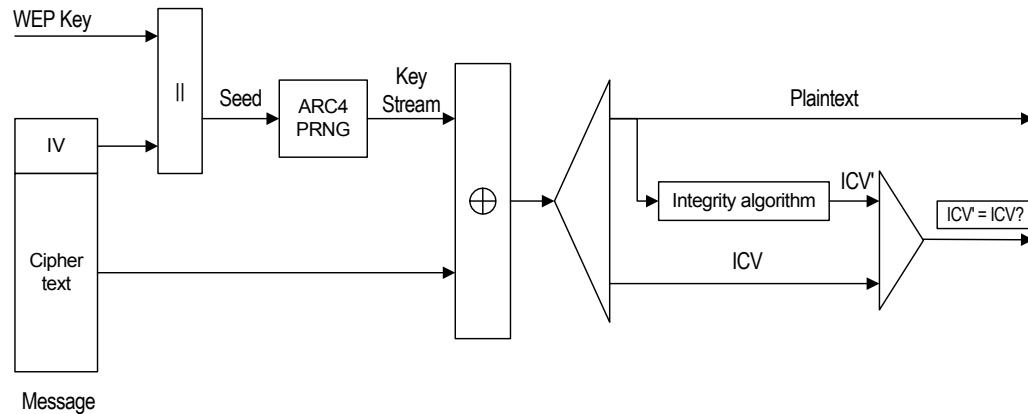

Figure 12-3—WEP decapsulation block diagram

12.3.3 Pre-RSNA authentication

12.3.3.1 Overview

In an infrastructure BSS, a non-DMG STA shall complete an IEEE 802.11 authentication exchange prior to association. A DMG STA not in an IBSS shall complete an IEEE 802.11 authentication exchange prior to association when an authentication algorithm other than the Open System authentication algorithm is requested. A DMG STA shall not perform an IEEE 802.11 authentication exchange using the Open System authentication algorithm. An IEEE 802.11 authentication exchange is optional in an IBSS.

All Authentication frames shall be individually addressed, as IEEE 802.11 authentication is performed between pairs of STAs, i.e., group addressed authentication is not allowed. Deauthentication frames are advisory and may be sent as group addressed frames.

Shared Key authentication is deprecated and should not be implemented except for backward compatibility with pre-RSNA STAs.

12.3.3.2 Open System authentication

12.3.3.2.1 General

Open System authentication is a null authentication algorithm.

Any non-DMG STA requesting Open System authentication can be authenticated if dot11AuthenticationAlgorithmsTable at the peer STA includes an entry with dot11AuthenticationAlgorithm equal to openSystem and dot11AuthenticationAlgorithmActivated equal to true.

A STA may decline to authenticate with another requesting STA. Open System authentication is the default authentication algorithm for a pre-RSNA STA.

Open System authentication utilizes a two-message authentication transaction sequence. The first message asserts identity and requests authentication. The second message returns the authentication result. If the result is “successful,” the STAs shall be declared mutually authenticated.

In the description in 12.3.3.2.2 and 12.3.3.2.3, the STA initiating the authentication exchange is referred to as the *requester*, and the STA to which the initial frame in the exchange is addressed is referred to as the *responder*. The specific items in each of the messages described in the following subclauses are defined in 9.3.3.12, Table 9-35, and Table 9-36.

12.3.3.2.2 Open System authentication (first frame)

Upon receipt of an Open System MLME-AUTHENTICATE.request primitive, the requester shall construct an Open System authentication request carried in an Authentication frame and transmit it to the responder.

12.3.3.2.3 Open System authentication (final frame)

Upon receipt of an Authentication frame requesting Open System authentication, the responder may authenticate the requester using the following procedure:

- a) Issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request.
- b) Construct and transmit a response carried in an Authentication frame with the fields as defined in 9.3.3.12 and the status field as defined in 9.4.1.9.

If dot11AuthenticationAlgorithmTable does not include an entry with dot11AuthenticationAlgorithm equal to openSystem and dot11AuthenticationAlgorithmActivated equal to true, the result code shall not take the value “successful.”

12.3.3.3 Shared Key authentication

12.3.3.3.1 General

Shared Key authentication seeks to authenticate STAs as either a member of those who know a shared secret key or a member of those who do not.

Shared Key authentication may be used if WEP has been selected and shall not be used otherwise.

This mechanism uses a shared key delivered to participating STAs via a secure channel that is independent of IEEE Std 802.11. This shared key is set in a write-only MIB attribute with the intent to keep the key value internal to the STA.

A STA shall not initiate a Shared Key authentication exchange unless dot11PrivacyOptionImplemented is true.

In the description in 12.3.3.3.2 to 12.3.3.3.6, the STA initiating the authentication exchange is referred to as the *requester*, and the STA to which the initial frame in the exchange is addressed is referred to as the *responder*. The specific items in each of the messages described in the following subclauses are defined in 9.3.3.12, Table 9-35, and Table 9-36.

12.3.3.3.2 Shared Key authentication (first frame)

Upon receipt of a Shared Key MLME-AUTHENTICATE.request primitive, the requester shall construct a Shared Key authentication request carried in an Authentication frame and transmit it to the responder.

12.3.3.3.3 Shared Key authentication (second frame)

Upon receipt of an Authentication frame requesting Shared Key authentication, the responder may authenticate the requester using the procedure here and in the following two frames:

- a) Issue an MLME-AUTHENTICATE.indication primitive to inform the SME of the authentication request.
- b) Before sending the second frame in the Shared Key authentication sequence, the responder shall use WEP to generate a string of octets to be used as the authentication challenge text.
- c) Construct and transmit to the requester a response carried in an Authentication frame with the fields as defined in 9.3.3.12 and the status field as defined in 9.4.1.9.

If the status code is not SUCCESS, this shall be the last frame of the transaction sequence; and the content of the challenge text field is unspecified.

If the status code is SUCCESS, the following additional information items shall have valid contents:

- Authentication algorithm dependent information = The challenge text
- This authentication result shall be of fixed length of 128 octets. The field shall be filled with octets generated by the WEP PRNG. The actual value of the challenge field is unimportant, but the value shall not be a static value.

12.3.3.4 Shared Key authentication (third frame)

The requester shall copy the challenge text from the second frame into a third Authentication frame. The third frame shall be transmitted to the responder after cryptographic encapsulation by WEP, as defined in 12.3.2, using the shared key.

12.3.3.5 Shared Key authentication (final frame)

The responder shall WEP-decapsulate the third frame as described in 12.3.2. If the WEP ICV check is successful, the responder shall compare the decrypted contents of the Challenge Text field with the challenge text sent in second frame. If they are the same, then the responder shall transmit an Authentication frame to the requester with a successful status code in the final frame of the sequence. If the WEP ICV check fails or challenge text comparison fails, the responder shall respond with an unsuccessful status code in final frame.

12.3.3.6 Shared key MIB attributes

To transmit a Management frame of subtype Authentication, with an Authentication Transaction Sequence Number field value of 2, the MAC shall operate according to the following decision tree:

```
if dot11PrivacyOptionImplemented is false then
    the MMPDU is transmitted with a sequence of 0 octets in the Challenge Text field and a status
    code value of UNSUPPORTED_AUTH_ALGORITHM
else
    the MMPDU is transmitted with a sequence of 128 octets generated using the WEP PRNG and
    a key whose value is unspecified and beyond the scope of this standard and a randomly chosen
    IV value (note that this is typically selected by the same mechanism for choosing IV values for
    transmitted Data frames) in the Challenge Text field and a status code value of SUCCESS (the
    IV used is immaterial and is not transmitted). Note that there are cryptographic issues involved
    in the choice of key/IV for this process as the challenge text is sent unencrypted and, therefore,
    provides a known output sequence from the PRNG.
endif
```

To receive a Management frame of subtype Authentication, with an Authentication Transaction Sequence Number field value of 2, the MAC shall operate according to the following decision tree:

```
if the Protected Frame subfield of the Frame Control field is 1 then
    respond with a status code value of CHALLENGE_FAILURE
else
    if dot11PrivacyOptionImplemented is true then
        if there is a mapping in dot11WEPKeyMappings matching the MSDU's TA then
            if that key is null then
                respond with a frame whose Authentication Transaction Sequence Number field
                is 3 that contains the appropriate authentication algorithm number, a status code
                value of CHALLENGE_FAILURE, and no Challenge Text field, without
                encrypting the contents of the frame
            else
                respond with a frame whose Authentication Transaction Sequence Number field
                is 3 that contains the appropriate authentication algorithm number, a status code
                value of SUCCESS, and the identical Challenge Text field, encrypted using that
                key, and setting the Key ID subfield in the IV field to 0
            endif
        else
            if dot11WEPDefaultKeys[dot11WEPDefaultKeyID] is null then
```

respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of CHALLENGE_FAILURE, and no Challenge Text field, without encrypting the contents of the frame

else

respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of SUCCESS, and the identical Challenge Text field, WEP-encapsulating the frame under the key dot11WEPDefaultKeys[dot11WEPDefaultKeyID], and setting the Key ID subfield in the IV field to dot11WEPDefaultKeyID

endif

endif

else

respond with a frame whose Authentication Transaction Sequence Number field is 3 that contains the appropriate authentication algorithm number, a status code value of UNSUPPORTED_AUTH_ALGORITHM, and no Challenge Text field, without encrypting the contents of the frame

endif

endif

When receiving a Management frame of subtype Authentication, with an Authentication Transaction Sequence Number field value of 3, the MAC shall operate according to the following decision tree:

if the Protected Frame subfield of the Frame Control field is 0 **then**

 respond with a status code value of CHALLENGE_FAILURE

else

if dot11PrivacyOptionImplemented is true **then**

if there is a mapping in dot11WEPKeyMappings matching the MSDU's TA **then**

if that key is null **then**

 respond with a frame whose Authentication Transaction Sequence Number field is 4 that contains the appropriate authentication algorithm number and a status code value of CHALLENGE_FAILURE without encrypting the contents of the frame

else

 WEP-decapsulate with that key, incrementing dot11WEPICVErrorCount and responding with a status code value of CHALLENGE_FAILURE if the ICV check fails

endif

else

if dot11WEPDefaultKeys[dot11WEPDefaultKeyID] is null **then**

 respond with a frame whose Authentication Transaction Sequence Number field is 4 that contains the appropriate authentication algorithm number and a status code value of CHALLENGE_FAILURE without encrypting the contents of the frame

else

 WEP-decapsulate with dot11WEPDefaultKeys[dot11WEPDefaultKeyID], incrementing dot11WEPICVErrorCount and responding with a status code value of CHALLENGE_FAILURE if the ICV check fails

endif

endif

else

 respond with a frame whose Authentication Transaction Sequence Number field is 4 that contains the appropriate authentication algorithm number and a status code value of CHALLENGE_FAILURE

```
    endif
  endif
```

dot11PrivacyInvoked shall not take the value of true if dot11PrivacyOptionImplemented is false. Setting dot11WEPKeyMappings to a value that includes more than dot11WEPKeyMappingLengthImplemented entries is illegal and shall have an implementation-specific effect on the operation of the data confidentiality service. Note that dot11WEPKeyMappings may contain from zero to dot11WEPKeyMappingLengthImplemented entries, inclusive.

The values of the attributes in the aPrivacygrp should not be changed during the authentication sequence, as unintended operation may result.

12.4 Authentication using a password

12.4.1 SAE overview

STAs, both AP STAs and non-AP STAs, may authenticate each other by proving possession of a password. Authentication protocols that employ passwords need to be resistant to off-line dictionary attacks.

Simultaneous authentication of equals (SAE) is a variant of *Dragonfly*, a password-authenticated key exchange based on a zero-knowledge proof. SAE is used by STAs to authenticate with a password; it has the following security properties:

- The successful termination of the protocol results in a PMK shared between the two STAs.
- An attacker is unable to determine either the password or the resulting PMK by passively observing an exchange or by interposing itself into the exchange by faithfully relaying messages between the two STAs.
- An attacker is unable to determine either the password or the resulting shared key by modifying, forging, or replaying frames to an honest, uncorrupted STA.
- An attacker is unable to make more than one guess at the password per attack. This implies that the attacker cannot make one attack and then go offline and make repeated guesses at the password until successful. In other words, SAE is resistant to dictionary attack.
- Compromise of a PMK from a previous run of the protocol does not provide any advantage to an adversary attempting to determine the password or the shared key from any other instance.
- Compromise of the password does not provide any advantage to an adversary in attempting to determine the PMK from the previous instance.

Unlike other authentication protocols SAE does not have a notion of an “Initiator” and “Responder” or of a “Supplicant” and “Authenticator.” The parties to the exchange are equals, with each side being able to initiate the protocol. Each side may initiate the protocol simultaneously such that each side views itself as the “initiator” for a particular run of the protocol. Such a peer-to-peer protocol may be used in a traditional client-server (or Supplicant/Authenticator) fashion but the converse does not hold. This requirement is necessary to address the unique nature of MBSSs.

The parties involved are called *STA-A* and *STA-B*. They are identified by their MAC addresses, STA-A-MAC and STA-B-MAC, respectively. STAs begin the protocol when they discover a peer by receiving Beacon or Probe Response frame(s), or when they receive an Authentication frame indicating SAE authentication from a peer.

SAE is an RSNA authentication protocol and is selected according to 12.6.2.

SAE shall be implemented on all mesh STAs to facilitate and promote interoperability.

12.4.2 Assumptions on SAE

SAE uses various functions and data to accomplish its task and assumes certain properties about each function. These are as follows:

- H is an “extractor” function (see IETF RFC 5869) that concentrates potentially dispersed entropy from an input to create an output that is a cryptographically strong, pseudorandom key. This function takes as input a non-secret “salt” and a secret input keying material “ikm” and produces a fixed-length output.
- CN is a confirmation function that takes a secret key and data to confirm and bind to the exchange.
- A finite cyclic group is negotiated for which solving the discrete logarithm problem is computationally infeasible.

When used with AKMs 00-0F-AC:8 or 00-0F-AC:9 from Table 9-133, H is instantiated as HMAC-SHA-256:

$$H(\text{salt}, \text{ikm}) = \text{HMAC-SHA-256}(\text{salt}, \text{ikm})$$

When used with AKMs 00-0F-AC:8 or 00-0F-AC:9 from Table 9-133, CN is instantiated as a function that takes a key, a counter, and a sequence of data. Each piece of data is converted to an octet string and concatenated together before being concatenated to the counter and passed, along with the key, to HMAC-SHA-256:

$$CN(\text{key}, \text{counter}, X, Y, Z, \dots) = \text{HMAC-SHA-256}(\text{key}, \text{counter} \parallel D2OS(X) \parallel D2OS(Y) \parallel D2OS(Z) \parallel \dots)$$

where D2OS() represents the data to octet string conversion functions in 12.4.7.2. Each invocation of CN() specifies the format of the counter.

Other instantiations of functions H and CN require creation of a new AKM identifier.

12.4.3 Representation of a password

Passwords are used in SAE to deterministically compute a secret element in the negotiated group, called a *password element*. The input to this process needs to be in the form of a binary string. For the protocol to successfully terminate, it is necessary for each side to produce identical binary strings for a given password, even if that password is in character format. There is no canonical binary representation of a character and ambiguity exists when the password is a character string. To eliminate this ambiguity, a STA shall represent a character-based password as an ASCII string. Representation of a character-based password in another character set or use of a password preprocessing technique (to map a character string to a binary string) may be agreed upon, in an out-of-band fashion, prior to beginning SAE. If the password is already in binary form (e.g., it is a binary preshared key) no character set representation is assumed. The binary representation of the password, after being transformed from a character representation or directly if it is already in binary form, is stored in the dot11RSNConfigPasswordValueTable. When a “password” is called for in the description of SAE that follows the credential from the dot11RSNConfigPasswordValueTable is used.

12.4.4 Finite cyclic groups

12.4.4.1 General

SAE uses discrete logarithm cryptography to achieve authentication and key agreement. Each party to the exchange derives ephemeral public and private keys with respect to a particular set of domain parameters that define a finite cyclic group. Groups may be based on either Finite Field Cryptography (FFC) or on Elliptic Curve Cryptography (ECC). Each component of a group is referred to as an *element*. Groups are negotiated using an identifying number from a repository maintained by IANA as “Group Description”

attributes for IETF RFC 2409 (IKE) [B17][B31]. The repository maps an identifying number to a complete set of domain parameters for the particular group. For the purpose of interoperability, a STA shall support group 19, an ECC group defined over a 256-bit prime order field.

More than one group may be configured on a STA for use with SAE by using the dot11RSNAConfigDLCGroup table. Configured groups are prioritized in ascending order of preference. If only one group is configured, it is, by definition, the most preferred group.

NOTE—The preference of one group over another is a local policy issue.

SAE uses three arithmetic operators defined for both FFC and ECC groups, an operation that takes two elements to produce a third element (called the *element operation*), an operation that takes an integer (called *scalar*) and an element to produce a second element (called the *scalar operation*), and an operation that takes an element to produce a second element (called the *inverse operation*). The convention used here is to represent group elements in uppercase bold italic and scalar values in lowercase italic. The element operation takes two elements, X and Y , to produce a third element, Z , and is denoted $Z = \text{elem-op}(X, Y)$; the scalar operation takes a scalar, x , and an element, Y , to produce a second element Z and is denoted $Z = \text{scalar-op}(x, Y)$; the inverse operation takes an element, X , to produce a second element, Z , and is denoted $Z = \text{inverse-op}(X)$.

$\text{scalar-op}(x, Y)$ is defined as successive iterations of $\text{elem-op}(Y, Y)$. That is, it is possible to define $\text{scalar-op}(1, Y) = Y$ and for $x > 1$, $\text{scalar-op}(x, Y) = \text{elem-op}(\text{scalar-op}(x-1, Y), Y)$. The specific definition of $\text{elem-op}(X, Y)$ depends on the type of group, either ECC or FFC.

12.4.4.2 Elliptic curve cryptography (ECC) groups

12.4.4.2.1 ECC group definition

ECC groups used by SAE are defined by the sextuple $(p, a, b, \mathbf{G}, r, h)$ where p is a prime number, a and b specify the elliptic curve defined by the equation, $y^2 = x^3 + ax + b \bmod p$, \mathbf{G} is a generator (a base point on the elliptic curve), r is the prime order of \mathbf{G} , and h is the co-factor. Elements in ECC groups are the points on the elliptic curve defined by their coordinates— (x, y) —that satisfy the equation for the curve and the identity element, the so-called “point at infinity.”

The IANA registry used to map negotiated numbers to group domain parameters includes some ECC groups defined over a characteristic 2 finite field and may include some ECC groups with a co-factor greater than 1. These groups shall not be used with SAE. Only ECC groups defined over an odd prime finite field with a co-factor equal to 1 shall be used with SAE.

The element operation in an ECC group is addition of two points on the curve resulting in a third point on the curve. For example, the point X is added to the point Y to produce the point Z :

$$Z = X + Y = \text{elem-op}(X, Y)$$

The scalar operation in an ECC group is multiplication of a point on the curve by a scalar resulting in a second point on the curve. For example, the point Y is multiplied by the scalar x to produce the point Z :

$$Z = xY = \text{scalar-op}(x, Y)$$

The inverse operation in an ECC group is inversion of a point on a curve resulting in a second point on the curve. A point on an elliptic curve is the inverse of a different point if their sum is the “point at infinity.” In other words:

$$\text{elem-op}(X, \text{inverse}(X)) = \text{“point at infinity”}$$

ECC groups make use of a mapping function, F, that maps a point (x, y) that satisfies the curve equation to its x-coordinate—i.e., if $\mathbf{P} = (x, y)$ then $F(\mathbf{P}) = x$. Function F is not defined with the identity element as input.

NOTE—SAE protocol operations preclude function F from ever being called with the identity element, i.e., the “point at infinity.”

12.4.4.2.2 Generation of the password element with ECC groups

The password element of an ECC group (**PWE**) shall be generated in a random hunt-and-peck fashion. The password and a counter, represented as a single octet and initially set to 1, are used with the peer identities to generate a password seed. The password seed shall then be stretched using the key derivation function (KDF) from 12.7.1.7.2 to a length equal to the bit length of the prime number, p , from the elliptic curve domain parameters with the Label being the string “SAE Hunting and Pecking” and with the Context being the prime number. If the resulting password value is greater than or equal to the prime number, the counter shall be incremented, a new password seed shall be derived and the hunting-and-pecking shall continue. Otherwise, it shall be used as the x-coordinate of a candidate point (x, y) on the curve satisfying the curve equation, if such a point exists. If no solution exists, the counter shall be incremented, a new password-seed shall be derived and the hunting-and-pecking shall continue. Otherwise, there are two possible solutions: (x, y) and $(x, p - y)$. The password seed shall be used to determine which one to use: if the least-significant bit (LSB) of the password seed is equal to that of y , the **PWE** shall be set to (x, y) ; otherwise, it shall be set to $(x, p - y)$.

In order to minimize the possibility of side-channel attacks that attempt to determine the number of interactions of the “hunting-and-pecking” loop required for a given <password, STA-A-MAC, STA-B-MAC> tuple, implementations should perform at least k iterations regardless of whether **PWE** is discovered or not. The value k may be set to any non-negative value and should be set to a sufficiently large number to effectively guarantee the discovery of **PWE** in less than k iterations. If **PWE** is discovered in less than k iterations a random “password” can be used in subsequent iterations to further obfuscate the true cost of discovering **PWE**.

NOTE—The probability that one requires more than n iterations of the “hunting and pecking” loop to find **PWE** is roughly $(r/2p)^n$, which rapidly approaches 0 as n increases.

Algorithmically this process is described as follows:

```

found = 0;
counter = 1
Length = len( $p$ )
base = password
do {
    pwd-seed = H(MAX(STA-A-MAC, STA-B-MAC) || MIN(STA-A-MAC, STA-B-MAC),
                  base || counter)
    pwd-value = KDF-Hash-Length(pwd-seed, “SAE Hunting and Pecking”,  $p$ )
    if (pwd-value <  $p$ )
        then
            if (pwd-value3 +  $a \times \text{pwd-value} + b$  is a quadratic residue modulo  $p$ )
                then
                    if (found==0)
                        then
                            x = pwd-value
                            save = pwd-seed
                            found = 1
                            base = a new random number
                fi
            fi
        fi
    fi
}

```

```

        counter = counter + 1
    } while ((counter <= k) or (found==0))
    y = sqrt(x3 + ax + b) mod p
    if (LSB(save) == LSB(y))
    then
        PWE = (x, y)
    else
        PWE = (x, p - y)
    fi

```

where

| | |
|--|--|
| KDF-Hash-Length len() | is the key derivation function defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133) returns the length of its argument in bits |
|--|--|

Checking whether a value is a quadratic residue modulo a prime can leak information that can be used in launching a side-channel attack. Therefore, a STA should use this blinding technique in determining a quadratic residue to address the possibility of a side-channel attack.

The blinding technique involves multiplication of the value with a random number so the value being checked for quadratic residue modulo a prime can take on all numbers between 1 and $p-1$ with equal probability. The blinded value is multiplied by a quadratic residue or quadratic non-residue depending on the value of a coin flip and the result is checked whether the result is a quadratic residue or quadratic non-residue, respectively.

This technique involves creation of a quadratic residue, qr , and quadratic non-residue, qnr , prior to beginning of the hunting-and-pecking loop. These values can be chosen at random by checking their legendre symbol:

```

do {
    qr = random() mod p
} while ( LGR(qr | p) is not equal to -1)

do {
    qnr = random() mod p
} while ( LGR(qnr | p) is not equal to 1)

```

The blinding technique of determining whether a value, v , is a quadratic residue modulo a prime, p , is then:

```

r = (random() mod (p - 1)) + 1
num = (v × r × r) mod p
if (LSB(r) == 1)
then
    num = (num × qr) mod p
    if (LGR(num | p) == 1)
    then
        v is a quadratic residue modulo p
    fi
else
    num = (num × qnr) mod p
    if (LGR(num | p) == -1)
    then
        v is a quadratic residue modulo p
    fi

```

fi
 \tilde{f}_i
 v is a quadratic non-residue modulo p

The values qr and qnr may be used for all loops in the hunting-and-pecking process but a new value for r shall be generated each time a quadratic residue is checked.

12.4.4.3 Finite field cryptography (FFC) groups

12.4.4.3.1 FFC group definition

FFC groups used by SAE are defined by the triple (p, \mathbf{G}, r) , where p is a prime number, \mathbf{G} is a generator, and r is the prime order of $\mathbf{G} \bmod p$. An element, \mathbf{B} , in an FFC group satisfies $\mathbf{B} = \mathbf{G}^i \bmod p$ for some integer i . This special property differentiates elements from scalars, even though both elements and scalars can be represented as non-negative integers less than the prime modulus p . The notation convention of 12.4.4 signifies this difference between an element and a scalar in an FFC group. The identity element for an FFC group is the value $1 \bmod p$.

The element operation in an FFC group is modular multiplication of two elements of this group resulting in a third element of this group. For example, the element \mathbf{X} is multiplied by the element \mathbf{Y} to produce the element \mathbf{Z} :

$$\mathbf{Z} = (\mathbf{XY}) \bmod p = \text{elem-op}(\mathbf{X}, \mathbf{Y})$$

The scalar operation in an FFC group is modular exponentiation of an element of this group by a scalar resulting in a second element of this group. For example, the point \mathbf{Y} is raised to the power x to produce the element \mathbf{Z} :

$$\mathbf{Z} = \mathbf{Y}^x \bmod p = \text{scalar-op}(x, \mathbf{Y})$$

Some FFC groups in the IANA repository are based on *safe primes*, i.e., a prime, p , of the form $p = 2q + 1$, where q is also a prime number. For these FFC groups, the group generated by \mathbf{G} always has order $r = (p - 1)/2$ and thus is uniquely derived from context. For other FFC groups, the parameter r shall be explicitly stated as part of the domain parameters.

The inverse operation in an FFC group is modular inversion of an element of this group producing a second element in this group. An element \mathbf{Z} is the inverse of a second element \mathbf{X} of this group if their modular product is the identity element of the FFC group. In other words:

$$\text{elem-op}(\mathbf{X}, \text{inverse}(\mathbf{X})) = 1 \bmod p$$

In contrast to ECC groups, FFC groups do not need a mapping function that maps an element of the FFC group to an integer (since those elements are already non-negative integers less than the prime number, p). However, for sake of uniform protocol definition, function F with FFC groups is defined as the identity function—i.e., if x is an element of the FFC group then $F(x) = x$.

12.4.4.3.2 Generation of the password element with FFC groups

The password element of an FFC group (**PWE**) shall be generated in a random hunt-and-peck fashion similar to the technique for an ECC group. The password and a counter, represented as a single octet and initially set to 1, are used with the two peer identities to generate a password seed. The password seed shall then be stretched using the key derivation function (KDF) from 12.7.1.7.2 to a length equal to the bit length

of the prime number, p , from the group domain parameters with the Label being the string “SAE Hunting and Pecking” and the Content being the prime number. If the resulting password value is greater than or equal to the prime number, the counter shall be incremented, a new password seed shall be derived, and the hunting-and-pecking shall continue. Otherwise, it shall be raised to the power $(p - 1) / r$ (where p is the prime number and r is the order) modulo the prime number to produce a candidate PWE . If the candidate PWE is greater than 1, the candidate PWE becomes the PWE ; otherwise, the counter shall be incremented, a new password seed shall be derived, and the hunting-and-pecking shall continue.

Algorithmically this process is described as follows:

```

found = 0;
counter = 1
Length = len( $p$ )
do {
    pwd-seed = H(MAX(STA-A-MAC, STA-B-MAC) || MIN(STA-A-MAC, STA-B-MAC),
                  password || counter)
    pwd-value = KDF-Hash-Length(pwd-seed, “SAE Hunting and Pecking”,  $p$ )
    if (pwd-value <  $p$ )
        then
             $PWE = \text{pwd-value}^{(p-1)/r} \bmod p$ 
            if ( $PWE > 1$ )
                then
                    found = 1
                fi
            fi
        counter = counter + 1
    } while (found == 0)
}

```

where

| | |
|---|--|
| <i>KDF-Hash-<i>Length</i></i> <i>len()</i> | is the key derivation function defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133) returns the length of its argument in bits |
|---|--|

12.4.5 SAE protocol

12.4.5.1 Message exchanges

The protocol consists of two message exchanges, a commitment exchange and a confirmation exchange. The commitment exchange is used to force each party to the exchange to commit to a single guess of the password. The confirmation exchange is used to prove that the password guess was correct. Authentication frames are used to perform these exchanges (see 9.3.3.12 and 12.4.7.3). The rules for performing these exchanges are specified by the finite state machine in 12.4.8.

When a party has sent its message in the commit exchange it is said to have *committed* and when it has sent its message in the confirmation exchange it has *confirmed*. The following rules are ascribed to the protocol:

- A party may *commit* at any time
- A party *confirms* after it has *committed* and its peer has *committed*
- A party *accepts* authentication after a peer has *confirmed*
- The protocol successfully *terminates* after each peer has *accepted*

12.4.5.2 PWE and secret generation

Prior to beginning the protocol message exchange, the secret element **PWE** and two secret values are generated. First, a group is selected, either the most preferred group if the STA is initiating SAE to a peer, or the group from a received SAE Commit message if the STA is responding to a peer. The **PWE** shall be generated for that group (according to 12.4.4.2.2 or 12.4.4.3.2, depending on whether the group is ECC or FFC, respectively) using the identities of the two STAs and the configured password.

After generation of the **PWE**, each STA shall generate a secret value, *rand*, and a temporary secret value, *mask*, each of which shall be chosen randomly such that $1 < \text{rand} < r$ and $1 < \text{mask} < r$ and $(\text{rand} + \text{mask}) \bmod r$ is greater than 1, where *r* is the (prime) order of the group. If their sum modulo *r* is not greater than 1, they shall both be irretrievably deleted and new values shall be randomly generated. The values *rand* and *mask* shall be random numbers produced from a quality random number drawn from a uniform distribution generator. These values shall never be reused on distinct protocol runs.

12.4.5.3 Construction of an SAE Commit message

An SAE Commit message consists of a scalar and an element that shall be produced using the **PWE** and secrets generated in 12.4.5.2, as follows:

$$\begin{aligned}\text{commit-scalar} &= (\text{rand} + \text{mask}) \bmod r \\ \text{COMMIT-ELEMENT} &= \text{inverse}(\text{scalar-op}(\text{mask}, \text{PWE}))\end{aligned}$$

This message shall be transmitted to the peer as described in 12.4.7. The temporary secret *mask* may be deleted at this point.

12.4.5.4 Processing of a peer's SAE Commit message

Upon receipt of a peer's SAE Commit message both the scalar and element shall be verified.

If the scalar value is greater than 0 and less than the order, *r*, of the negotiated group, scalar validation succeeds; otherwise, it fails. Element validation depends on the type of group. For FFC groups, the element shall be an integer greater than 1 and less than the prime number *p* minus 1, (*p* – 1), and the scalar operation of the element and the order of the group, *r*, shall equal 1 modulo the prime number *p*. If either of these conditions does not hold, element validation fails; otherwise, it succeeds. For ECC groups, both the x- and y-coordinates of the element shall be non-negative integers less than the prime number *p*, and the two coordinates shall produce a valid point on the curve satisfying the group's curve definition, not being equal to the “point at the infinity.” If either of those conditions does not hold, element validation fails; otherwise, element validation succeeds.

If either scalar validation or element validation fails, the STA shall reject the peer's authentication. If both the scalar and element from the peer's SAE Commit message are successfully validated, a shared secret element, *K*, shall be derived using the scalar and element (*peer-commit-scalar* and **PEER-COMMIT-ELEMENT**, respectively) from the peer's SAE Commit message and the STA's secret value.

$$\begin{aligned}\text{K} &= \text{scalar-op}(\text{rand}, (\text{elem-op}(\text{scalar-op}(\text{peer-commit-scalar}, \text{PWE}), \\ &\quad \text{PEER-COMMIT-ELEMENT})))\end{aligned}$$

If the shared secret element, *K*, is the identity element for the negotiated group (the value one for an FFC group or the point-at-infinity for an ECC group) the STA shall reject the peer's authentication. Otherwise, a secret value, *k*, shall be computed as:

$$k = F(K)$$

The entropy of k shall then be extracted using H to produce *keyseed*. The key derivation function from 12.7.1.7.2 shall then be used with the hash algorithm identified by the AKM suite selector (see Table 9-133) to derive a key confirmation key, KCK, and a pairwise master key, PMK, from *keyseed*. When used with AKMs 8 or 9, the salt shall consist of thirty-two (32) octets of the value 0 (indicated below as <0>32) and both the KCK and PMK shall be 256 bits in length, and therefore the length of keying material derived is 512. Use of other AKMs require definition of the lengths of the salt, the KCK, and the PMK.

$$\begin{aligned} \text{keyseed} &= H(<0>32, k) \\ \text{kck_and_pmk} &= \text{KDF-Hash-512}(\text{keyseed}, \text{"SAE KCK and PMK"}, \\ &\quad (\text{commit-scalar} + \text{peer-commit-scalar}) \bmod r) \\ \text{KCK} &= L(\text{kck_and_pmk}, 0, 256) \\ \text{PMK} &= L(\text{kck_and_pmk}, 256, 256) \end{aligned}$$

where

KDF-Hash-512 is the key derivation function defined in 12.7.1.7.2 using the hash algorithm defined by the negotiated AKM in Table 9-133.

The PMK identifier is defined as follows:

$$\text{PMKID} = L((\text{commit-scalar} + \text{peer-commit-scalar}) \bmod r, 0, 128)$$

12.4.5.5 Construction of an SAE Confirm message

A peer generates an SAE Confirm message by passing the KCK, the current value of the *send-confirm* counter (see 9.4.1.38), the scalar and element from the sent SAE Commit message, and the scalar and element from the received SAE Commit message to the confirmation function CN.

$$\text{confirm} = \text{CN}(\text{KCK}, \text{send-confirm}, \text{commit-scalar}, \textbf{COMMIT-ELEMENT}, \text{peer-commit-scalar}, \textbf{PEER-COMMIT-ELEMENT})$$

The *send-confirm* counter shall be in the format specified in subclause 9.2.2 in the order in which it is transmitted over the air. The message shall be transmitted to the peer as described in 12.4.7.

12.4.5.6 Processing of a peer's SAE Confirm message

Upon receipt of a peer's SAE Confirm message a *verifier* is computed, which is the expected value of the peer's confirmation, *peer-confirm*, extracted from the received an SAE Confirm message. The *verifier* is computed by passing the KCK, the peer's send-confirm counter from the received an SAE Confirm message (see 9.4.1.38), the scalar and element from the received SAE Commit message, and scalar and element from the sent SAE Commit message to the confirmation function CN.

$$\text{verifier} = \text{CN}(\text{KCK}, \text{peer-send-confirm}, \text{peer-commit-scalar}, \textbf{PEER-COMMIT-ELEMENT}, \text{commit-scalar}, \textbf{COMMIT-ELEMENT})$$

The *peer-send-confirm* shall be in the format in subclause 9.2.2, as extracted out of the received frame. If the *verifier* equals *peer-confirm*, the STA shall accept the peer's authentication and set the lifetime of the PMK to the value dot11RSNAConfigPMKLifetime. If the *verifier* differs from the *peer-confirm*, the STA shall reject the peer's authentication and delete the PMK.

12.4.6 Anti-clogging tokens

A STA is required to do a considerable amount of work upon receipt of an SAE Commit message. This opens up the possibility of a distributed denial-of-service attack by flooding a STA with bogus SAE Commit

messages from forged MAC addresses. To prevent this from happening, a STA shall maintain an *Open* counter in its SAE state machine indicating the number of open and unfinished protocol instances (see 12.4.5.1). When that counter hits or exceeds dot11RSNASEAntiCloggingThreshold, the STA shall respond to each SAE Commit message with a rejection that includes an Anti-Clogging Token statelessly bound to the sender of the SAE Commit message. The sender of the SAE Commit message shall then include this Anti-Clogging Token in a subsequent SAE Commit message.

The Anti-Clogging Token is a variable-length value that statelessly binds the MAC address of the sender of an SAE Commit message. The length of the Anti-Clogging Token needs not be specified because the generation and processing of the Anti-Clogging Token is solely up to one peer. To the other peer in the SAE protocol, the Anti-Clogging Token is merely an opaque blob whose length is insignificant. It is suggested that an Anti-Clogging Token not exceed 256 octets.

NOTE—A suggested method for producing Anti-Clogging Tokens is to generate a random secret value each time the state machine variable hits dot11RSNASEAntiCloggingThreshold and pass that secret and the MAC address of the sender of the SAE Commit message to the random function H to generate the token.

As long as the state machine variable *Open* is greater than or equal to dot11RSNASEAntiCloggingThreshold all SAE Commit messages that do not include a valid Anti-Clogging Token shall be rejected with a request to repeat the SAE Commit message and include the token (see 12.4.5.1).

Since the Anti-Clogging Token is of fixed size and the size of the *peer-commit-scalar* and **PEER-COMMIT-ELEMENT** are inferred from the finite cyclic group being used, it is straightforward to determine whether a received SAE Commit message includes an Anti-Clogging Token or not.

Encoding of the Anti-Clogging Token and its placement with respect to the *peer-commit-scalar* and **PEER-COMMIT-ELEMENT** is described in 12.4.7.4.

12.4.7 Framing of SAE

12.4.7.1 General

SAE Commit messages and SAE Confirm messages are sent and received by a SAE protocol using Authentication frames.

12.4.7.2 Data type conversion

12.4.7.2.1 General

This protocol requires elements in finite cyclic groups to be converted to octet strings prior to transmission and back again upon receipt. To convert an element into an octet string, the first step is to represent the element in integer format and then employ an integer-to-octet string conversion prior to transmission. To convert an octet string into an element requires an octet string to integer conversion and then representing the integer(s) as an element.

12.4.7.2.2 Integer to octet string conversion

An integer, x , shall be converted into an octet string of length m such that $2^{8m} > x$ by first representing x in its binary form and then converting the result to an octet-string.

Given x , m , represent x as a sequence of x_{m-i} base 2⁸.

$$x = x_{m-1} \times 2^{8(m-1)} + x_{m-2} \times 2^{8(m-2)} + \dots + x_1 \times 2^8 + x_0$$

then let the octet M_i have the value x_i for $0 \leq i \leq m-1$, and the octet string shall be $M_{m-1} \parallel M_{m-2} \parallel \dots \parallel M_1 \parallel M_0$.

12.4.7.2.3 Octet string to integer conversion

An octet string shall be converted into an integer by viewing the octet string as the base 2^8 representation of the integer.

$$x = \sum_{i=1}^{m} 2^{8(m-i)} \times M_{m-i}$$

12.4.7.2.4 Element to octet string conversion

For ECC groups, each element, except the “point at infinity,” is a point on the elliptic curve satisfying the curve equation and consists of two components: an x-coordinate and a y-coordinate. To convert this point to an octet string, each component shall be treated as an integer and converted into an octet string whose length is the smallest integer m such that $2^{8m} > p$, where p is the prime number specified by the elliptic curve domain parameters, according to 12.4.7.2.2. The point shall be represented as the concatenation of the x-coordinate and the y-coordinate, each represented as an octet string of length m octets, and is $2m$ octets long.

For FFC groups each element is a non-negative integer less than the prime number p specified by the FFC domain parameters. To convert this element into an octet string, it shall be treated directly as an integer and converted into an octet string whose length is the smallest integer m such that $2^{8m} > p$, where p is the prime number specified by the domain parameters, according to 12.4.7.2.2.

12.4.7.2.5 Octet string to element conversion

To convert an octet string into a point on an elliptic curve it is necessary to divide it into two octet strings of equal length m . If the length of the octet string does not evenly divide by two, conversion shall fail. Each octet string of length m shall be converted to an integer according to 12.4.7.2.3. The first octet string conversion produces an integer that becomes the x-coordinate of the point and the second octet string conversion produces an integer that becomes the y-coordinate of the point. If either integer equals 0 or is greater than or equal to p , the prime from the elliptic curve domain parameters, conversion shall fail. If the resulting (x, y) point does not satisfy the equation of the curve, or produces the “point at infinity,” conversion shall fail.

To convert an octet string into an element in a prime modulus group the octet string shall be converted into an integer according to 12.4.7.2.3 and the integer shall be used directly as the group element.

12.4.7.3 Authentication transaction sequence number for SAE

An SAE Commit message shall use authentication transaction sequence number 1. an SAE Confirm message shall use authentication transaction sequence number 2.

12.4.7.4 Encoding and decoding of SAE Commit messages

An SAE Commit message shall be encoded as an Authentication frame with an Authentication Algorithm Number field set to 3, a Transaction Sequence Number of 1 and a Status Code of SUCCESS Status codes not equal to SUCCESS indicate a rejection of a peer’s SAE Commit message and are described in 12.4.7.6.

An SAE Commit message shall consist of a Finite Cyclic Group field (9.4.1.43) indicating a group, a Scalar field (9.4.1.40) containing the scalar, and an FFE field containing the element (9.4.1.41). If the SAE Commit

message is in response to an Anti-Clogging Token request (see 12.4.7.6), the Anti-Clogging Token is present (see 9.4.1.39).

When transmitting an SAE Commit message, the scalar and element shall be converted to octet strings and placed in the Scalar field and FFE field, respectively. The scalar shall be treated as an integer and converted into an octet string of length m such that $2^{8m} > r$, where r is the order of the group, according to 12.4.7.2.2, and the element shall be converted into (an) octet string(s) according to 12.4.7.2.4. When receiving an SAE Commit message the component octet strings in the Scalar field and Element field shall be converted into a scalar and element, respectively, according to 12.4.7.2.3 and 12.4.7.2.5, respectively.

12.4.7.5 Encoding and decoding of SAE Confirm messages

An SAE Confirm message shall be encoded as an Authentication frame with an Authentication Algorithm Number field set to 3, a Transaction Sequence Number of 2 and a Status Code of SUCCESS. Status codes not equal to SUCCESS indicate rejection of a peer's SAE Confirm message and are described in 12.4.7.6.

An SAE Confirm message shall consist of a Send-Confirm field (9.4.1.38) and a Confirm field (9.4.1.42) containing the output of the random function as described in 12.4.5.5. When transmitting an SAE Confirm message the output of the random function shall be treated as an integer and converted into an octet string of length m , where m is the block size of the random function, according to 12.4.7.2.2 and placed in the Confirm field. When receiving an SAE Confirm message, the octet string in the Confirm field shall be converted into an integer representing the peer's Confirm according to 12.4.7.2.3.

12.4.7.6 Status codes

An SAE Commit message with a status code not equal to SUCCESS shall indicate that a peer rejects a previously sent SAE Commit message. An unsupported finite cyclic group is indicated with a status code of UNSUPPORTEDFINITECYCLICGROUP, “Authentication is rejected because the offered finite cyclic group is not supported.” An Anti-Clogging Token is requested by transmitting an SAE Commit message with a status code of ANTI_CLOGGING_TOKEN_REQUIRED, “Anti-Clogging Token Requested,” with the Anti-Clogging Token occupying the Token field of the Authentication frame.

An SAE Confirm message, with a status code not equal to SUCCESS, shall indicate that a peer rejects a previously sent SAE Confirm message. An SAE Confirm message that was not successfully verified is indicated with a status code of CHALLENGE_FAILURE.

12.4.8 SAE finite state machine

12.4.8.1 General

The protocol is instantiated by the finite state machine in Figure 12-4. Each instance of the protocol is identified by a tuple consisting of the local MAC address and the peer MAC address. The model in which SAE is defined consists of a parent process, managed by the SME, which receives messages, and dispatches them to the appropriate protocol instance, also managed by the SME. The parent process manages a database of protocol instances indexed by the peer identity. Protocol instances maintain state, receive events from the parent process, send events to itself, and output data.

NOTE—Figure 12-4 does not show all state machine transitions. A full description of the SAE finite state machine is in 12.4.8.6.2 to 12.4.8.6.6.

The parent process instantiates protocol instances upon receipt of SAE messages and initiation by SME. The parent process also maintains a counter of the number of protocol instances created.

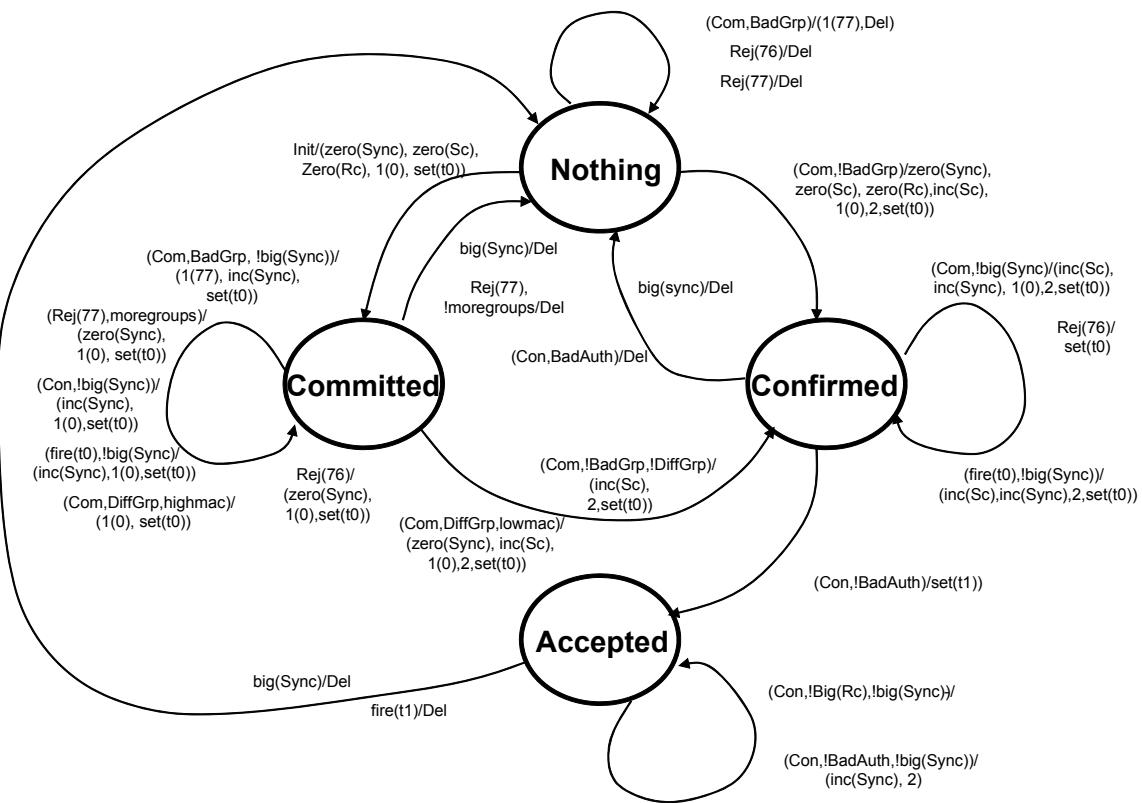

Figure 12-4—SAE finite state machine

12.4.8.2 States

12.4.8.2.1 Parent process states

The parent process is in a continuous quiescent state.

12.4.8.2.2 Protocol instance states

Each protocol instance is in one of the following four states:

- *Nothing*—The *Nothing* state represents the initial state of a freshly allocated protocol instance or the terminal state of a soon-to-be deallocated protocol instance. Freshly created protocol instances will immediately transition out of *Nothing* state depending on the reason for their creation. Protocol instances that transition into *Nothing* state shall immediately be irretrievably deleted.
- *Committed*—In the *Committed* state, the finite state machine has sent an SAE Commit message and is awaiting an SAE Commit message and an SAE Confirm message from the peer.
- *Confirmed*—In the *Confirmed* state, the finite state machine has sent both an SAE Commit message and an SAE Confirm message and received an SAE Commit message. It awaits an SAE Confirm message.
- *Accepted*—In the *Accepted* state, the protocol instance has both sent and received an SAE Commit message and an SAE Confirm message and the protocol instance has finished.

12.4.8.3 Events and output

12.4.8.3.1 Parent process events and output

The parent process receives events from three sources: the SME, protocol instances, and received frames.

The SME signals the following events to the parent SAE process:

- *Initiate*—An *Initiate* event is used to instantiate a protocol instance to begin SAE with a designated peer.
- *Kill*—A *Kill* event is used to remove a protocol instance with a designated peer.

Protocol instances send the following events to the SAE parent process:

- *Fail*—The peer failed to be authenticated.
- *Auth*—The peer was successfully authenticated.
- *Del*—The protocol instance has had a fatal event.

Receipt of frames containing SAE messages signals the following events to the SAE parent process:

- *Authentication frame with Transaction Sequence number 1*—This event indicates that an SAE Commit message has been received from a peer STA.
- *Authentication frame with Transaction Sequence number 2*—This event indicates that an SAE Confirm message has been received from a peer STA.

The parent process generates Authentication frames with Authentication transaction sequence 1 and a Status of 76 indicating rejection of an Authentication attempt because an Anti-Clogging Token is required.

12.4.8.3.2 Protocol instance events and output

The protocol instance receives events from the parent SAE process.

- *Com*—Indicates receipt of an SAE Commit message (authentication transaction sequence number 1) with a status of 0.
- *Con*—Indicates receipt of an SAE Confirm message (authentication transaction sequence number 2) with a status of 0.
- *Init*—Indicates that the protocol instance should begin negotiation with a specified peer.
- *Rej(N)*—Indicates receipt of a rejected SAE Commit message with status *N*.

In addition, protocol instances receive *fire(X)* events indicating the expiration of timer *X*. Upon expiration of a timer and generation of a *fire()* event, the expired timer is not reset.

The protocol instance generates output from the following events:

- *I(N)*—Indicates generation of an SAE Commit message (authentication transaction sequence number 1) with status *N*.
- *2*—Indicates generation of an SAE Confirm message (authentication transaction sequence number 2).

12.4.8.4 Timers

The parent SAE process does not use timers. Each protocol instance can set timers that result in *fire()* events to be sent to itself. The following timers can be set:

- *t0*—A retransmission timer.
- *t1*—A PMK expiration timer.

Timers are set by the protocol instance issuing a *set()* for the particular timer.

12.4.8.5 Variables

12.4.8.5.1 Parent process variables

The parent SAE process maintains a counter, *Open*, which indicates the number of protocol instances in either *Committed* or *Confirmed* state. When the parent SAE process starts up, *Open* is set to 0.

The parent process maintains a database of protocol instances.

NOTE—Depending on how Anti-Clogging Tokens (see 12.4.6) are constructed, the parent SAE process might also maintain a random secret used for token creation.

12.4.8.5.2 Protocol instance variables

Each protocol instance maintains the following three variables:

- *Sync*—The number of state resynchronizations that have occurred.
- *Sc*—The number of SAE Confirm messages that have been sent. This is the send-confirm counter used in the construction of SAE Confirm messages (see 12.4.5.5).
- *Rc*—The received value of the *send-confirm* counter in the last received SAE Confirm message. In other words, this is the value of the peer’s send-confirm counter.

Function *zero(X)* assigns the value 0 to the variable *X*, *inc(X)* increments the variable *X*, and *big(X)* indicates that the variable *X* has exceeded a maximum value.

In addition, protocol instances maintain the following six indicators that are not maintained as state variables but, instead, indicate the cause of certain behavior.

- *BadGrp*—The group specified in an SAE Commit message is not supported.
- *DiffGrp*—The group specified in an SAE Commit message is supported but differs from the one offered.
- *BadConf*—The contents of a confirm frame were incorrect.
- *highmac*—The peer identity is numerically less than the local identity.
- *lowmac*—The peer identity is numerically greater than the local identity.
- *moregroups*—There are finite cyclic groups in the configuration that have not been offered to the peer.

A negative indication is shown with an exclamation point (!)—e.g., “the group specified in an SAE Commit message is supported” would be !BadGrp, which is read as “not BadGrp.”

12.4.8.6 Behavior of state machine

12.4.8.6.1 Parent process behavior

For any given peer identity, there shall be only one protocol instance in *Committed* or *Confirmed* state. Similarly, for any given peer identity, there shall be only one protocol instance in *Accepted* state.

The parent process creates protocol instances based upon different actions. Creating a protocol instance entails allocation of state necessary to maintain the protocol instance state machine, putting the protocol instance in *Nothing* state, incrementing the *Open* counter, and inserting the protocol instance into its database indexed by the MAC address of the peer with whom the protocol instance will communicate.

The parent process shall delete protocol instances irretrievably.

Upon receipt of an *Initiate* event, the parent process shall check whether there exists a protocol instance for the peer MAC address (from the *Init* event) in either *Committed* or *Confirmed* state. If there is, the *Initiate* event shall be ignored. Otherwise, a protocol instance shall be created, and an *Init* event shall be sent to the protocol instance.

Upon receipt of a *Kill* event, the parent process shall delete all protocol instances indexed by the peer MAC address (from the *Kill* event) in its database. For each protocol instance in *Committed* or *Confirmed* state, the *Open* counter shall be decremented.

Upon receipt of a *Sync*, *Del*, or *Fail* event from a protocol instance, the parent process shall decrement the *Open* counter and deletes the protocol instance.

Upon receipt of an *Auth* event from a protocol instance, the parent process shall decrement the *Open* counter. If another protocol instance exists in the database indexed by the same peer identity as the protocol instance that sent the *Auth* event, the other protocol instance shall be deleted.

Upon receipt of an SAE Commit message, the parent process checks whether a protocol instance for the peer MAC address exists in the database. If one does, and it is in either *Committed* state or *Confirmed* state the frame shall be passed to the protocol instance. If one does and it is in *Accepted* state, the scalar in the received frame is checked against the *peer-scalar* used in authentication of the existing protocol instance (in *Accepted* state). If it is identical, the frame shall be dropped. If not, the parent process checks the value of *Open*. If *Open* is greater than `dot11RSNASEAntiCloggingThreshold`, the parent process shall check for the presence of an Anti-Clogging Token. If an Anti-Clogging Token exists and is correct, the parent process shall create a protocol instance. If the Anti-Clogging Token is incorrect, the frame shall be silently discarded. If *Open* is greater than or equal to `dot11RSNASEAntiCloggingThreshold` and there is no Anti-Clogging Token in the received frame, the parent process shall construct a response as an Authentication frame with the Authentication Transaction Sequence Number field set to 1, the Status Code field set to `ANTI_CLOGGING_TOKEN_REQUIRED`, and the body of the frame consisting of an Anti-Clogging Token (see 12.4.6). If *Open* is less than `dot11RSNASEAntiCloggingThreshold`, the parent process shall create a protocol instance and the frame shall be sent to the protocol instance as a *Com* event.

Upon receipt of an SAE Confirm message, the parent process checks whether a protocol instance for the peer MAC address (as indicated by the SA in the received frame) exists in the database. If there is a single protocol instance, the frame shall be passed to it as a *Con* event. If there are two protocol instances indexed by that peer MAC address, the frame shall be passed, as a *Con* event, to the protocol instance that is not in *Accepted* state. If there are no protocol instances indexed by that peer MAC address, the frame shall be dropped.

12.4.8.6.2 Protocol instance behavior—General

State machine behavior is illustrated in Figure 12-4. The protocol instance receives events from the parent process and from itself. It generates SAE messages that are transmitted to a peer and sends events to itself and the parent process.

The semantics of the state diagram are “occurrence/behavior” where “occurrence” is a comma-separated list of events and/or indicators, or the special symbol “—” indicating no occurrence; and, “behavior” is a comma-separated list of outputs and/or functions, or the special symbol “—” indicating no behavior.

When the state machine calls for the t0 (retransmission) timer to be set, it shall be set to `dot11RSNASERetransPeriod`. When the state machine calls for the t1 (key expiration) timer to be set, it shall be set to `dot11RSNAConfigPMKLifetime`.

12.4.8.6.3 Protocol instance behavior - Nothing state

In *Nothing* state a protocol instance has just been allocated.

Upon receipt of an *Init* event, the protocol instance shall zero its *Sync* variable, *Rc*, and *Sc* variables, select a group from local configuration and generate the **PWE** and the secret values according to 12.4.5.2, generate an SAE Commit message (see 12.4.5.3), and set its t0 (retransmission) timer. The protocol instance transitions into *Committed* state.

Upon receipt of a *Com* event, the protocol instance shall check the Status of the Authentication frame. If the Status code is not SUCCESS, the frame shall be silently discarded and a *Del* event shall be sent to the parent process. Otherwise, the frame shall be processed by first checking the finite cyclic group field to see if the requested group is supported. If not, *BadGrp* shall be set and the protocol instance shall construct and transmit a an Authentication frame with Status code UNSUPPORTEDFINITECYCLICGROUP indicating rejection with the finite cyclic group field set to the rejected group, and shall send the parent process a *Del* event. If the group is supported, the protocol instance shall zero the *Sc* and *Rc* counters and it shall generate the **PWE** and the secret values according to 12.4.5.2. It shall then process the received SAE Commit message (see 12.4.5.4). If validation of the received SAE Commit message fails, the protocol instance shall send a *Del* event to the parent process; otherwise, it shall construct and transmit an SAE Commit message (see 12.4.5.3) followed by an SAE Confirm message (see 12.4.5.5). The *Sync* counter shall be set to 0 and the t0 (retransmission) timer shall be set. The protocol instance transitions to *Confirmed* state.

NOTE—A protocol instance in *Nothing* state will never receive an SAE Confirm message due to state machine behavior of the parent process.

12.4.8.6.4 Protocol instance behavior - Committed state

In *Committed* state, a protocol instance has sent its peer an SAE Commit message but has yet to receive (and accept) anything.

Upon receipt of a *Com* event, the t0 (retransmission) timer shall be canceled. Then the following is performed:

- The protocol instance shall check the Status code of the Authentication frame. If the Status code is ANTI_CLOGGING_TOKEN_REQUIRED, a new SAE Commit message shall be constructed with the Anti-Clogging Token from the received Authentication frame, and the *commit-scalar* and **COMMIT-ELEMENT** previously sent. The new SAE Commit message shall be transmitted to the peer, *Sync* shall be zeroed, and the t0 (retransmission) timer shall be set.
- If the Status code is UNSUPPORTEDFINITECYCLICGROUP, the protocol instance shall check the finite cyclic group field being rejected. If the rejected group does not match the last offered group the protocol instance shall silently discard the message and set the t0 (retransmission) timer. If the rejected group matches the last offered group, the protocol instance shall choose a different group and generate the **PWE** and the secret values according to 12.4.5.2; it then generates and transmits a new SAE Commit message to the peer, zeros *Sync*, sets the t0 (retransmission) timer, and remains in *Committed* state. If there are no other groups to choose, the protocol instance shall send a *Del* event to the parent process and transitions back to *Nothing* state.
- If the Status is some other nonzero value, the frame shall be silently discarded and the t0 (retransmission) timer shall be set.
- If the Status is zero, the finite cyclic group field is checked. If the group is not supported, *BadGrp* shall be set and the value of *Sync* shall be checked.
 - If *Sync* is greater than dot11RSNASAESync, the protocol instance shall send a *Del* event to the parent process and transitions back to *Nothing* state.
 - If *Sync* is not greater than dot11RSNASAESync, *Sync* shall be incremented, an SAE Commit message with Status code equal to UNSUPPORTEDFINITECYCLICGROUP indicating

- rejection, and the Algorithm identifier set to the rejected algorithm shall be sent to the peer, the t0 (retransmission) timer shall be set and the protocol instance shall remain in *Committed* state.
- If the group is supported but does not match that used when the protocol instance constructed its SAE Commit message, *DiffGrp* shall be set and the local identity and peer identity shall be checked.
 - The mesh STA, with the numerically greater of the two MAC addresses, drops the received SAE Commit message, retransmits its last SAE Commit message, and shall set the t0 (retransmission) timer and remain in *Committed* state.
 - The mesh STA, with the numerically lesser of the two MAC addresses, zeros *Sync*, shall increment *Sc*, choose the group from the received SAE Commit message, generate new **PWE** and new secret values according to 12.4.5.2, process the received SAE Commit message according to 12.4.5.4, generate a new SAE Commit message and SAE Confirm message, and shall transmit the new Commit and Confirm to the peer. It shall then transition to *Confirmed* state.
 - If the group is supported and matches that used when the protocol instance constructed its SAE Commit message, the protocol instance checks the *peer-commit-scalar* and **PEER-COMMIT-ELEMENT** from the message. If they match those sent as part of the protocol instance's own SAE Commit message, the frame shall be silently discarded (because it is evidence of a reflection attack) and the t0 (retransmission) timer shall be set. If the received element and scalar differ from the element and scalar offered, the received SAE Commit message shall be processed according to 12.4.5.4, the *Sc* counter shall be incremented (thereby setting its value to one), the protocol instance shall then construct an SAE Confirm message, transmit it to the peer, and set the t0 (retransmission) timer. It shall then transition to *Confirmed* state.

If the t0 (retransmission) timer fires, the value of the *Sync* counter is checked. If *Sync* is greater than dot11RSNASAESync, the protocol instance shall send a *Del* event to the parent process and transition back to *Nothing* state. If *Sync* is not greater than dot11RSNASAESync, the *Sync* counter shall be incremented, the last message sent shall be sent again, and the t0 (retransmission) timer shall be set.

Upon receipt of a *Con* event, the t0 (retransmission) timer shall be canceled. Then the protocol instance checks the value of *Sync*. If it is greater than dot11RSNASAESync, the protocol instance shall send a *Del* event to the parent process and transition back to *Nothing* state. If *Sync* is not greater than dot11RSNASAESync, the protocol instance shall increment *Sync*, transmit the last SAE Commit message sent to the peer, and set the t0 (retransmission) timer.

12.4.8.6.5 Protocol instance behavior - Confirmed state

In *Confirmed* state, a protocol instance has sent its peer an SAE Commit message and SAE Confirm message. It has received an SAE Commit message from its peer.

Rejection frames received in *Confirmed* state shall be silently discarded.

Upon receipt of a *Com* event, the t0 (retransmission) timer shall be canceled. If the Status is nonzero, the frame shall be silently discarded, the t0 (retransmission) timer set, and the protocol instance shall remain in the *Confirmed* state. If *Sync* is greater than dot11RSNASAESync, the protocol instance shall send the parent process a *Del* event and transitions back to *Nothing* state. If *Sync* is not greater than dot11RSNASAESync, the protocol instance shall verify that the finite cyclic group is the same as the previously received Commit frame. If not, the frame shall be silently discarded. If so, the protocol instance shall increment *Sync*, increment *Sc*, and transmit its Commit and Confirm (with the new *Sc* value) messages. It then shall set the t0 (retransmission) timer.

Upon receipt of a *Con* event, the t0 (retransmission) timer shall be canceled and the SAE Confirm message shall be processed according to 12.4.5.6. If processing is successful and the SAE Confirm message has been

verified, the Rc variable shall be set to the send-confirm portion of the frame, Sc shall be set to the value $2^{16} - 1$, the $t1$ (key expiration) timer shall be set, and the protocol instance shall transition to *Accepted* state.

If the $t0$ (retransmission) timer fires, the value of the *Sync* counter shall be checked. If *Sync* is greater than `dot11RSNASAESync`, the protocol instance shall send a *Del* event to the parent process and transition back to *Nothing* state. If *Sync* is not greater than `dot11RSNASAESync`, the *Sync* counter shall be incremented, Sc shall be incremented, and the protocol instance shall create a new Confirm (with the new Sc value) Message, transmit it to the peer, and set the $t0$ (retransmission) timer.

12.4.8.6.6 Protocol instance behavior - Accepted state

In *Accepted* state, a protocol instance has sent an SAE Commit message and an SAE Confirm message to its peer and received an SAE Commit message and SAE Confirm message from the peer. Unfortunately, there is no guarantee that the final SAE Confirm message sent by the STA was received by the peer.

Upon receipt of a *Con* event, the *Sync* counter shall be checked. If the value is greater than `dot11RSNASAESync`, the protocol instance shall send a *Del* event to the parent process and shall transition to *Nothing* state. If the value of *Sync* is not greater than `dot11RSNASAESync`, the value of send-confirm shall be checked. If the value is not greater than Rc or is equal to $2^{16} - 1$, the received frame shall be silently discarded. Otherwise, the Confirm portion of the frame shall be checked according to 12.4.5.6. If the verification fails, the received frame shall be silently discarded. If the verification succeeds, the Rc variable shall be set to the send-confirm portion of the frame, the *Sync* shall be incremented and a new SAE Confirm message shall be constructed (with Sc set to $2^{16} - 1$) and sent to the peer. The protocol instance shall remain in *Accepted* state.

If the $t1$ (key expiration) timer fires, the protocol instance shall send the parent process a *Del* event and transition to *Nothing* state.

12.5 RSNA confidentiality and integrity protocols

12.5.1 Overview

This standard defines the following RSNA data confidentiality and integrity protocols: TKIP, CCMP, and GCMP. This standard defines one integrity protocol for Management frames: BIP.

Implementation of TKIP is optional for an RSNA and used only for the protection of Data frames. A design aim for TKIP was that the algorithm should be implementable within the capabilities of most devices supporting only WEP, so that many such devices would be field-upgradable by the supplier to support TKIP.

BIP is a mechanism that is used only when management frame protection is negotiated. BIP provides integrity protection for group addressed robust Management frames. BIP is used only to protect Management frames within the BSS.

12.5.2 Temporal key integrity protocol (TKIP)

12.5.2.1 TKIP overview

12.5.2.1.1 General

The TKIP is a cipher suite enhancing WEP on pre-RSNA hardware. TKIP modifies WEP as follows:

- a) A transmitter calculates a keyed cryptographic message integrity code (MIC) over the MSDU SA and DA, the MSDU priority (see 12.5.2.3), and the MSDU plaintext data. TKIP appends the computed MIC to the MSDU data prior to fragmentation into MPDUs. The receiver verifies

the MIC after decryption, ICV checking, and defragmentation of the MPDUs into an MSDU and discards any received MSDUs with invalid MICs. TKIP's MIC provides a defense against forgery attacks.

- b) Because of the design constraints of the TKIP MIC, it is still possible for an adversary to compromise message integrity; therefore, TKIP also implements countermeasures. The countermeasures bound the probability of a successful forgery and the amount of information an attacker can learn about a key.
- c) TKIP uses a per-MPDU TKIP sequence counter (TSC) to sequence the MPDUs it sends. The receiver drops MPDUs received out of order, i.e., not received with increasing sequence numbers. This provides replay protection. TKIP encodes the TSC value from the sender to the receiver as a WEP IV and extended IV.
- d) TKIP uses a cryptographic mixing function to combine a temporal key, the TA, and the TSC into the WEP seed. The receiver recovers the TSC from a received MPDU and utilizes the mixing function to compute the same WEP seed needed to correctly decrypt the MPDU. The key mixing function is designed to defeat weak-key attacks against the WEP key.

TKIP defines additional MIB variables; see Annex C.

12.5.2.1.2 TKIP cryptographic encapsulation

TKIP enhances the WEP cryptographic encapsulation with several additional functions, as depicted in Figure 12-5.

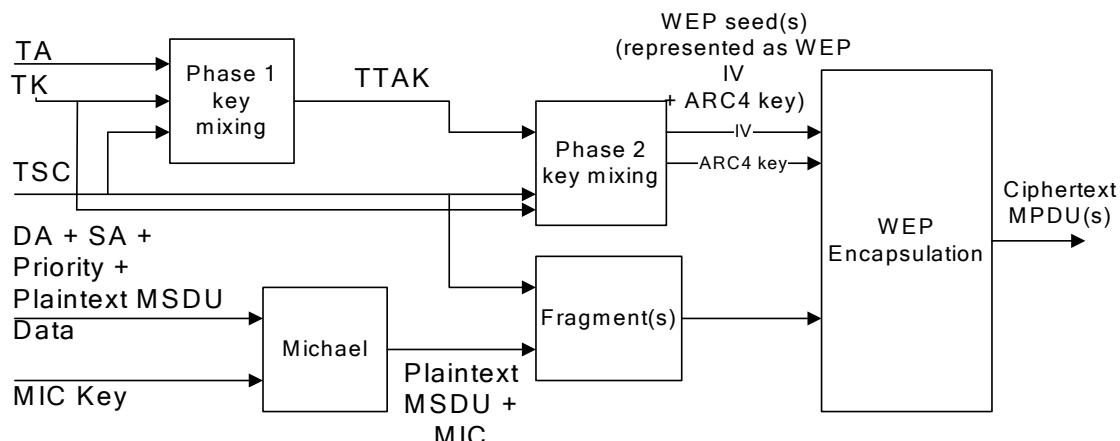

Figure 12-5—TKIP encapsulation block diagram

- a) TKIP MIC computation protects the MSDU Data field and corresponding SA, DA, and Priority fields. The computation of the MIC is performed on the ordered concatenation of the SA, DA, Priority, and MSDU Data fields. The MIC is appended to the MSDU Data field. TKIP discards any MIC padding prior to appending the MIC.
- b) If needed, the MSDU with MIC is fragmented into one or more MPDUs. TKIP assigns a monotonically increasing TSC value to each MPDU, taking care that all of the MPDUs generated from the same MSDU have the same value of extended IV (see 12.5.2.2).
- c) For each MPDU, TKIP uses the key mixing function to compute the WEP seed.
- d) TKIP represents the WEP seed as a WEP IV and ARC4 key and passes these with each MPDU to WEP for generation of the ICV (see 9.2.4.7), and for encryption of the plaintext MPDU, including all or part of the MIC, if present. WEP uses the WEP seed as a WEP default key, identified by a key identifier associated with the temporal key.

NOTE—When the TSC space is exhausted, the choices available to an implementation are to replace the temporal key with a new one or to end communications. Reuse of any TSC value compromises already sent traffic. Note that retransmitted MPDUs reuse the TSC without any compromise of security. The TSC is large enough, however, that TSC space exhaustion is not expected to be an issue.

In Figure 12-5, the TKIP-mixed transmit address and key (TTAK) denotes the intermediate key produced by Phase 1 of the TKIP mixing function (see 12.5.2.5).

12.5.2.1.3 TKIP decapsulation

TKIP enhances the WEP decapsulation process with the following additional steps:

- Before WEP decapsulates a received MPDU, TKIP extracts the TSC sequence number and key identifier from the WEP IV and the extended IV. TKIP discards a received MPDU that violates the sequencing rules (see 12.5.2.6) and otherwise uses the mixing function to construct the WEP seed.
- TKIP represents the WEP seed as a WEP IV and ARC4 key and passes these with the MPDU to WEP for decapsulation.
- If WEP indicates the ICV check succeeded, the implementation reassembles the MPDU into an MSDU. If the MSDU defragmentation succeeds, the receiver verifies the TKIP MIC. If MSDU defragmentation fails, then the MSDU is discarded.
- The MIC verification step recomputes the MIC over the MSDU SA, DA, Priority, and MSDU Data fields (but not the TKIP MIC field). The calculated TKIP MIC result is then compared bitwise to the received MIC.
- If the received and the locally computed MIC values are identical, the verification succeeds, and TKIP shall deliver the MSDU to the upper layer. If the two differ, then the verification fails; the receiver shall discard the MSDU and shall engage in appropriate countermeasures.

Figure 12-6 depicts this process.

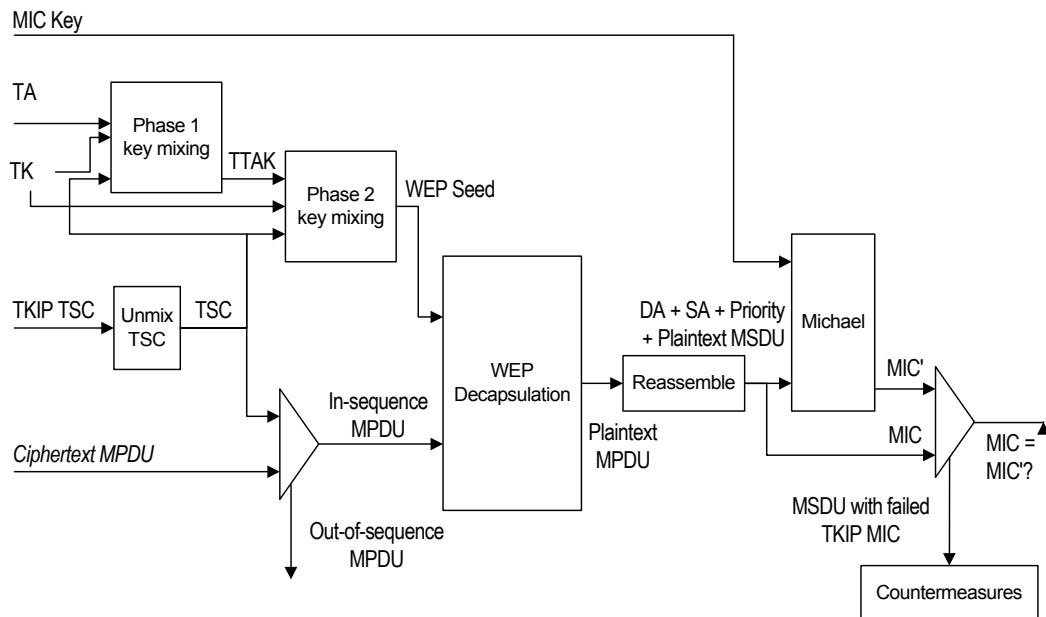

Figure 12-6—TKIP decapsulation block diagram

12.5.2.2 TKIP MPDU formats

TKIP reuses the pre-RSNA WEP MPDU format. It extends the MPDU by 4 octets to accommodate an extension to the WEP IV, denoted by the Extended IV field, and extends the MSDU format by 8 octets to accommodate the new MIC field. TKIP inserts the Extended IV field immediately after the WEP IV field and before the encrypted data. TKIP appends the MIC to the MSDU Data field; the MIC becomes part of the encrypted data.

Once the MIC is appended to the MSDU data, the added MIC octets are considered part of the MSDU for subsequent fragmentation.

Figure 12-7 depicts the layout of the encrypted MPDU when using TKIP. Note that the figure only depicts the case when the MSDU can be encapsulated in a single MPDU.

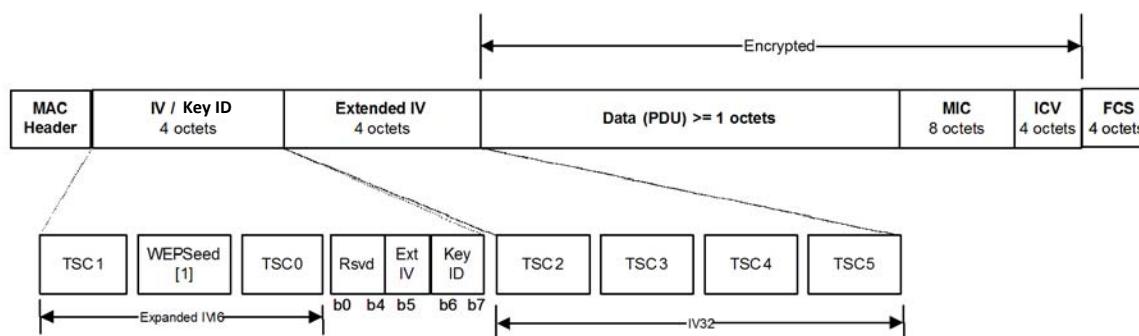

Figure 12-7—Construction of expanded TKIP MPDU

The ExtIV bit in the Key ID octet indicates the presence or absence of an extended IV. If the ExtIV bit is 0, only the nonextended IV is transferred. If the ExtIV bit is 1, an extended IV of 4 octets follows the original IV. For TKIP the ExtIV bit shall be set to 1, and the Extended IV field shall be supplied. The ExtIV bit shall be 0 for WEP frames. The Key ID field shall be set to the key index supplied by the MLME-SETKEYS.request primitive for the key used in cryptographic encapsulation of the frame.

TSC5 is the most significant octet of the TSC, and TSC0 is the least significant. Octets TSC0 and TSC1 form the IV sequence number and are used with the TKIP Phase 2 key mixing. Octets TSC2–TSC5 are used in the TKIP Phase 1 key hashing and are in the Extended IV field. When the lower 16-bit sequence number rolls over ($0xFFFF \rightarrow 0x0000$), the extended IV value, i.e., the upper 32 bits of the entire 48-bit TSC, shall be incremented by 1.

NOTE—The rationale for this construction is as follows:

- Aligning on word boundaries eases implementation on legacy devices.
 - Adding 4 octets of extended IV eliminates TSC exhaustion as a reason to rekey.
 - Key ID octet changes. Bit 5 indicates that an extended IV is present. The receiver/transmitter interprets the 4 octets following the Key ID as the extended IV. The receiving/transmitting STA also uses the value of octets TSC0 and TSC1 to detect that the cached TTAK needs to be updated.

The Extended IV field shall not be encrypted.

WEPSeed[1] is not used to construct the TSC, but is set to $(TSC1 \mid 0x20) \& 0x7f$.

TKIP shall encrypt all of the MPDUs generated from one MSDU under the same temporal key.

12.5.2.3 TKIP MIC

12.5.2.3.1 General

Flaws in the IEEE 802.11 WEP design cause it to fail to meet its goal of protecting data traffic content from casual eavesdroppers. Among the most significant WEP flaws is the lack of a mechanism to defeat message forgeries and other active attacks. To defend against active attacks, TKIP includes a MIC, called *michael*. This MIC offers only weak defenses against message forgeries, but it constitutes the best that can be achieved with the majority of legacy hardware. TKIP uses different MIC keys depending on the direction of the transfer as described in 12.8.1 and 12.8.2.

Annex J contains an implementation of the TKIP MIC. It also provides test vectors for the MIC.

12.5.2.3.2 Motivation for the TKIP MIC

Before defining the details of the MIC, it is useful to review the context in which this mechanism operates. Active attacks enabled by the original WEP design include the following:

- Bit-flipping attacks
- Data (payload) truncation, concatenation, and splicing
- Fragmentation attacks
- Iterative guessing attacks against the key
- Redirection by modifying the MPDU DA or RA field
- Impersonation attacks by modifying the MPDU SA or TA field

The MIC makes it more difficult for any of these attacks to succeed.

All of these attacks remain at the MPDU level with the TKIP MIC. The MIC, however, applies to the MSDU, so it blocks successful MPDU-level attacks. TKIP applies the MIC to the MSDU at the transmitter and verifies it at the MSDU level at the receiver. If a MIC check fails at the MSDU level, the implementation shall discard the MSDU and invoke countermeasures (see 12.5.2.4).

Informative Figure 12-8 depicts different peer layers communicating.

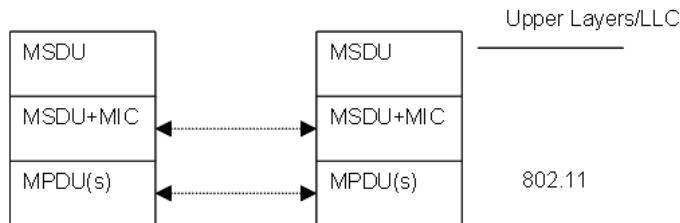

Figure 12-8—TKIP MIC relation to IEEE 802.11 processing (informative)

This figure depicts an architecture where the MIC is logically appended to the raw MSDU in response to the MA-UNITDATA.request primitive. The TKIP MIC is computed over

- The MSDU DA
- The MSDU SA
- The MSDU Priority
- The entire unencrypted MSDU data (payload)

The DA field, SA field, three reserved octets, and a 1-octet Priority field are used only for calculating the MIC. The Priority field refers to the priority parameter of the MA-UNITDATA.request primitive. The fields in Figure 12-9 are treated as an octet stream using the conventions described in 9.2.2.

| 6 | 6 | 1 | 3 | M | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | octets |
|----|----|----------|---|------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| DA | SA | Priority | 0 | Data | M 0 | M 1 | M 2 | M 3 | M 4 | M 5 | M 6 | M 7 | |

Figure 12-9—TKIP MIC processing format

TKIP appends the MIC at the end of the MSDU. The MIC is 8 octets in size for michael. The IEEE 802.11 MAC then applies its normal processing to transmit this MSDU-with-MIC as a sequence of one or more MPDUs. In other words, the MSDU-with-MIC can be partitioned into one or more MPDUs, the WEP ICV is calculated over each MPDU, and the MIC can even be partitioned to lie in two MPDUs after fragmentation. The TKIP MIC augments, but does not replace, the WEP ICV. Because the TKIP MIC is a weak construction, TKIP protects the MIC with encryption, which makes TKIP MIC forgeries more difficult. The WEP ICV helps to prevent false detection of MIC failures that would cause countermeasures to be invoked.

The receiver reverses this procedure to reassemble the MSDU; and, after the MSDU has been logically reassembled, the IEEE 802.11 MAC verifies the MIC prior to delivery of the MSDU to upper layers. If the MIC validation succeeds, the MAC delivers the MSDU. If the MIC validation fails, the MAC shall discard the MSDU and invoke countermeasures (see 12.5.2.4).

NOTE—TKIP calculates the MIC over the MSDU rather than the MPDU, because doing so increases the implementation flexibility with preexisting WEP hardware.

Note that a MIC alone cannot provide complete forgery protection, as it cannot defend against replay attacks. Therefore, TKIP provides replay detection by TSC sequencing and ICV validation. Furthermore, if TKIP is utilized with a GTK, an insider STA can masquerade as any other STA belonging to the group.

12.5.2.3.3 Definition of the TKIP MIC

Michael generates a 64-bit MIC. The michael key consists of 64 bits, represented as an 8-octet sequence, $k_0 \dots k_7$. This is converted to two 32-bit words, K_0 and K_1 . Throughout this subclause, all conversions between octets and 32-bit words shall use the little endian conventions, given in 9.2.2.

Michael operates on each MSDU including the Priority field, 3 reserved octets, SA field, and DA field. An MSDU consists of octets $m_0 \dots m_{n-1}$ where n is the number of MSDU octets, including SA, DA, Priority, and Data fields. The message is padded at the end with a single octet with value 0x5a, followed by between 4 and 7 zero octets. The number of zero octets is chosen so that the overall length of the padded MSDU is a multiple of four. The padding is not transmitted with the MSDU; it is used to simplify the computation over the final block. The MSDU is then converted to a sequence of 32-bit words $M_0 \dots M_{N-1}$, where $N = \lceil (n+5)/4 \rceil$. By construction, $M_{N-1} = 0$ and $M_{N-2} \neq 0$.

The MIC value is computed iteratively starting with the key value (K_0 and K_1) and applying a block function b for every message word, as shown in Figure 12-10. The algorithm loop runs a total of N times (i takes on the values 0 to $N-1$ inclusive), where N is as above, the number of 32-bit words composing the padded MSDU. The algorithm results in two words (l and r), which are converted to a sequence of 8 octets using the least-significant-octet-first convention:

- $M_0 = l \& 0xff$
- $M_1 = (l/0x100) \& 0xff$
- $M_2 = (l/0x10000) \& 0xff$
- $M_3 = (l/0x1000000) \& 0xff$

- $M4 = r \& 0xff$
- $M5 = (r/0x100) \& 0xff$
- $M6 = (r/0x10000) \& 0xff$
- $M7 = (r/0x1000000) \& 0xff$

This is the MIC value. The MIC value is appended to the MSDU as data to be sent.

Input: Key (K_0, K_1) and padded MSDU (represented as 32-bit words) $M_0 \dots M_{N-1}$

Output: MIC value (V_0, V_1)

```

MICHAEL(( $K_0, K_1$ ) , ( $M_0, \dots, M_N$ ))
( $I, r$ )  $\leftarrow$  ( $K_0, K_1$ )
for  $i = 0$  to  $N-1$  do
     $I \leftarrow I \oplus M_i$ 
    ( $I, r$ )  $\leftarrow b(I, r)$ 
return ( $I, r$ )

```

Figure 12-10—Michael message processing

Figure 12-11 defines the michael block function b . It is a Feistel-type construction with alternating additions and XOR operations. It uses $<<<$ to denote the rotate-left operator on 32-bit values, $>>>$ for the rotate-right operator, and XSWAP for a function that swaps the position of the 2 least significant octets. It also uses the position of the two most significant octets in a word.

```

Input: ( $I, r$ )
Output: ( $I, r$ )
 $b(L, R)$ 
     $r \leftarrow r \oplus (I <<< 17)$ 
     $I \leftarrow (I + r) \bmod 2^{32}$ 
     $r \leftarrow r \oplus \text{XSWAP}(I)$ 
     $I \leftarrow (I + r) \bmod 2^{32}$ 
     $r \leftarrow r \oplus (I <<< 3)$ 
     $I \leftarrow (I + r) \bmod 2^{32}$ 
     $r \leftarrow r \oplus (I >>> 2)$ 
     $I \leftarrow (I + r) \bmod 2^{32}$ 
return ( $I, r$ )

```

Figure 12-11—Michael block function

12.5.2.4 TKIP countermeasures procedures

12.5.2.4.1 General

The TKIP MIC trades off security in favor of implementability on pre-RSNA STAs. Michael provides only weak protection against active attacks. A failure of the MIC in a received MSDU indicates a probable active attack. A successful attack against the MIC would mean an attacker could inject forged Data frames and perform further effective attacks against the encryption key itself. If TKIP implementation detects a probable active attack, TKIP shall take countermeasures as specified in this subclause. These countermeasures accomplish the following goals:

- MIC failure events should be logged as a security-relevant matter. A MIC failure is an almost certain indication of an active attack and warrants a follow-up by the system administrator.
- The rate of MIC failures needs to be kept below two per minute. This implies that STAs and APs detecting two MIC failure events within 60 s need to disable all receptions using TKIP for a period of 60 s. The slowdown makes it difficult for an attacker to make a large number of forgery attempts in a short time.

- As an additional security feature, the PTK and, in the case of the Authenticator, the GTK should be changed.

Before verifying the MIC, the receiver shall check the FCS, ICV, and TSC for all related MPDUs. Any MPDU that has an invalid FCS, an incorrect ICV, or a TSC value that is less than or equal to the TSC replay counter shall be discarded before checking the MIC. This avoids unnecessary MIC failure events. Checking the TSC before the MIC makes countermeasure-based denial-of-service attacks harder to perform. While the FCS and ICV mechanisms are sufficient to detect noise, they are insufficient to detect active attacks. The FCS and ICV provide error detection, but not integrity protection.

A single counter or timer shall be used to log MIC failure events. These failure events are defined as follows:

- In an Authenticator:
 - Detection of a MIC failure on a received individually addressed frame.
 - Receipt of Michael MIC Failure Report frame.
- In a Supplicant:
 - Detection of a MIC failure on a received individually addressed or group addressed frame.
 - Attempt to transmit a Michael MIC Failure Report frame.

The number of MIC failures is accrued independent of the particular key context. Any single MIC failure, whether detected by the Supplicant or the Authenticator and whether resulting from a group MIC key failure or a pairwise MIC key failure, shall be treated as cause for a MIC failure event.

The Supplicant uses a single Michael MIC Failure Report frame to report a MIC failure event to the Authenticator. A Michael MIC Failure Report is an EAPOL-Key frame with the following Key Information field bits set to 1: MIC bit, Error bit, Request bit, Secure bit. The Supplicant protects this message with the current PTK; the Supplicant uses the KCK portion of the PTK to compute the IEEE 802.1X EAPOL MIC.

The MLME-MICHAELMICFAILURE.indication primitive is used by the IEEE 802.11 MAC to attempt to indicate a MIC failure to the local IEEE 802.1X Supplicant or Authenticator. MLME-EAPOL.request primitive is used by the Supplicant to send the EAPOL-Key frame containing the Michael MIC Failure report. MLME-EAPOL.confirm primitive indicates to the Supplicant when the EAPOL-Key frame has been transmitted.

The first MIC failure shall be logged, and a timer initiated to enable enforcement of the countermeasures. If the MIC failure event is detected by the Supplicant, it shall also report the event to the AP by sending a Michael MIC Failure Report frame.

If a subsequent MIC failure occurs within 60 s of the most recent previous failure, then a STA whose IEEE 802.1X entity has acted as a Supplicant shall deauthenticate (as defined in 11.3.4.4) itself or deauthenticate all of the STAs with a security association if its IEEE 802.1X entity acted as an Authenticator. In an IBSS STA, both Supplicant and Authenticator actions shall be taken. Furthermore, the device shall not receive or transmit any TKIP-encrypted Data frames, and shall not receive or transmit any unencrypted Data frames other than IEEE 802.1X messages, to or from any peer for a period of at least 60 s after it detects the second failure. If the device is an AP, it shall disallow new associations using TKIP during this 60 s period; at the end of the 60 s period, the AP shall resume normal operations and allow STAs to (re)associate. If the device is an IBSS STA, it shall disallow any new security associations using TKIP during this 60 s period. If the device is a Supplicant, it shall first send a Michael MIC Failure Report frame prior to revoking its PTKSA and deauthenticating itself.

The aMICFailTime attribute shall contain the sysUpTime value at the time the MIC failure was logged.

12.5.2.4.2 TKIP countermeasures for an Authenticator

The countermeasures used by an Authenticator are depicted in Figure 12-12 and described as follows:

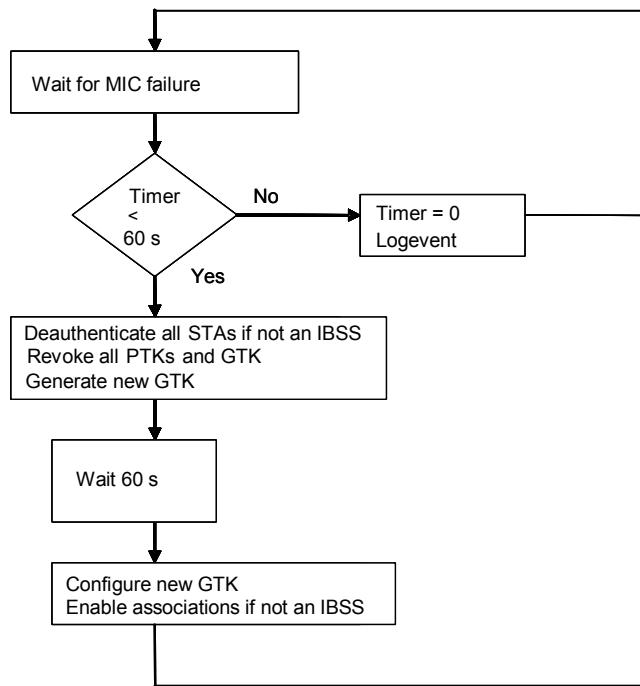

Figure 12-12—Authenticator MIC countermeasures

- a) In an Authenticator’s STA that receives a frame with a MIC error,
 - 1) Discard the frame.
 - 2) Increment the MIC failure counter, `dot11RSNAStatsTKIPLocalMICFailures`.
 - 3) Generate an `MLME-MICHAELMICFAILURE.indication` primitive.
- b) In an Authenticator that receives an `MLME-MICHAELMICFAILURE.indication` primitive or a Michael MIC Failure Report frame,
 - 1) If it is a Michael MIC Failure Report frame, then increment `dot11RSNAStatsTKIP-RemoteMICFailures`.
 - 2) If this is the first MIC failure within the past 60 s, initialize the countermeasures timer.
 - 3) If less than 60 s have passed since the most recent previous MIC failure, the Authenticator shall deauthenticate and delete all PTKSAs for all STAs using TKIP. If the current GTKSA uses TKIP, that GTKSA shall be discarded, and a new GTKSA constructed, but not used for 60 s. The Authenticator shall refuse the construction of new PTKSAs using TKIP as one or more of the ciphers for 60 s. At the end of this period, the MIC failure counter and timer shall be reset, and creation of PTKSAs accepted as usual.
 - 4) If the Authenticator is using IEEE 802.1X authentication, the Authenticator shall transition the state of the IEEE 802.1X Authenticator state machine to the INITIALIZE state. This restarts the IEEE 802.1X state machine. If the Authenticator is instead using PSKs, this step is omitted.

Note that a Supplicant’s STA may deauthenticate with a reason code of `MIC_FAILURE` if it is an ESS STA. The Authenticator shall not log the deauthentication as a MIC failure event to prevent denial-of-service attacks through deauthentications. The Supplicant’s STA reports the MIC failure event through the Michael MIC Failure Report frame so that the AP can log the event.

The requirement to deauthenticate all STAs using TKIP includes those using other pairwise ciphers if they are using TKIP as the group cipher.

12.5.2.4.3 TKIP countermeasures for a Supplicant

The countermeasures used by a Supplicant are depicted in Figure 12-13 and described as follows:

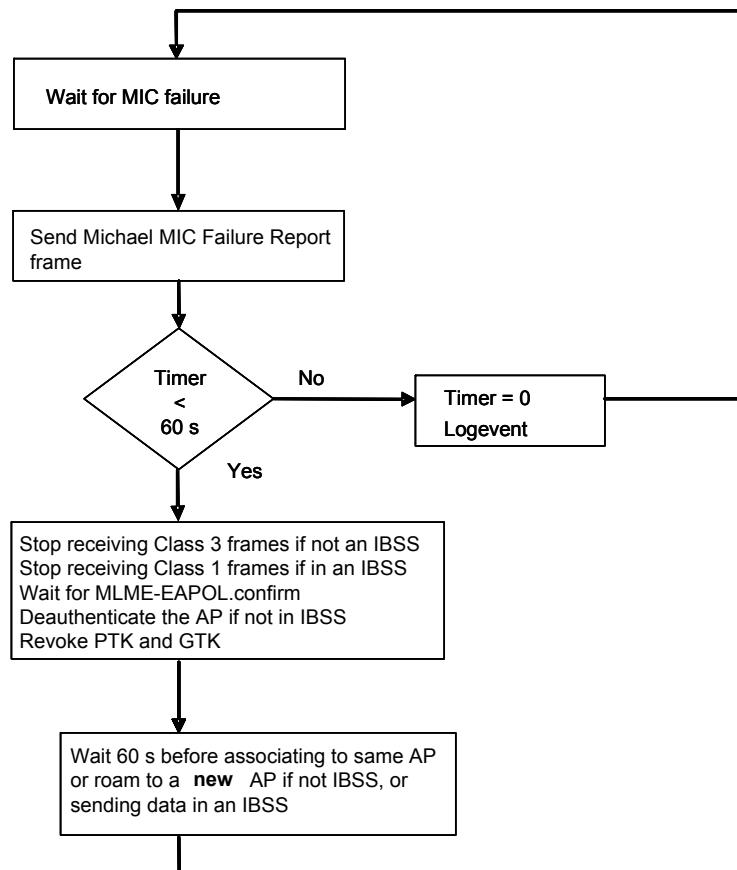

Figure 12-13—Supplicant MIC countermeasures

- a) In a Supplicant's STA that receives a frame with a MIC error,
 - 1) Increment the MIC failure counter, `dot11RSNAStatsTKIPLocalMICFailures`.
 - 2) Discard the offending frame.
 - 3) Generate an `MLME-MICHAELMICFAILURE.indication` primitive.
- b) In a Supplicant that receives an `MLME-MICHAELMICFAILURE.indication` primitive from its STA,
 - 1) Send a Michael MIC Failure Report frame to the AP.
 - 2) If this is the first MIC failure within the past 60 s, initialize the countermeasures timer.
 - 3) If less than 60 s have passed since the most recent previous MIC failure, delete the PTKSA and GTKSA. Deauthenticate from the AP and wait for 60 s before (re)establishing a TKIP association with the same AP. A TKIP association is any IEEE 802.11 association that uses TKIP for its pairwise or group cipher suite.
- c) If a STA receives a deauthenticate frame with the reason code `MIC_FAILURE` it is unable to verify that the frame has not been forged, since the frame does not contain a MIC. The STA may attempt association with this, or another, AP. If the frame was genuine, then it is probable that attempts to

associate with the same AP requesting the use of TKIP will fail because the AP is conducting countermeasures.

12.5.2.5 TKIP mixing function

12.5.2.5.1 General

Annex J defines a C-language reference implementation of the TKIP mixing function. It also provides test vectors for the mixing function.

The mixing function has two phases. Phase 1 mixes the appropriate temporal key (pairwise or group) with the TA and TSC. A STA may cache the output of this phase to reuse with subsequent MPDUs associated with the same temporal key and TA. Phase 2 mixes the output of Phase 1 with the TSC and temporal key (TK) to produce the WEP seed, also called the *per-frame key*. The WEP seed may be precomputed before it is used. The two-phase process may be summarized as follows:

```
TTAK := Phase1 (TK, TA, TSC)
WEP seed := Phase2 (TTAK, TK, TSC)
```

12.5.2.5.2 S-Box

Both Phase 1 and Phase 2 rely on an S-box, defined in this subclause. The S-box substitutes one 16-bit value with another 16-bit value. This function may be implemented as a table look up.

NOTE—The S-box is a nonlinear substitution. The table look-up is be organized as either a single table with 65 536 entries and a 16-bit index (128K octets of table) or two tables with 256 entries and an 8-bit index (1024 octets for both tables). When the two smaller tables are used, the high-order octet is used to obtain a 16-bit value from one table, the low-order octet is used to obtain a 16-bit value from the other table, and the S-box output is the XOR of the two 16-bit values. The second S-box table is an octet-swapped replica of the first.

```
#define _S_(v16)      (Sbox[0][Lo8(v16)] ^ Sbox[1][Hi8(v16)])  
  
/* 2-byte by 2-byte subset of the full AES S-box table */
const u16b Sbox[2][256]=      /* Sbox for hash (can be in ROM)      */
{ {
    0xC6A5, 0xF884, 0xEE99, 0xF68D, 0xFF0D, 0xD6BD, 0xDEB1, 0x9154,
    0x6050, 0x0203, 0xCEA9, 0x567D, 0xE719, 0xB562, 0x4DE6, 0xEC9A,
    0x8F45, 0x1F9D, 0x8940, 0xFA87, 0xEF15, 0xB2EB, 0x8EC9, 0xFB0B,

12.5.2.5.3 Phase 1 Definition

The inputs to Phase 1 of the temporal key mixing function shall be a temporal key (TK), the TA, and the TSC. The temporal key shall be 128 bits in length. Only the 32 MSBs of the TSC and all of the temporal key are used in Phase 1. The output, $TTAK$, shall be 80 bits in length and is represented by an array of 16-bit values: $TTAK_0\ TTAK_1\ TTAK_2\ TTAK_3\ TTAK_4$.

The description of the Phase 1 algorithm treats all of the following values as arrays of 8-bit values: $TA_0..TA_5$, $TK_0..TK_{15}$. The TA octet order is represented according to the conventions from 9.2.2, and the first 3 octets represent the OUI.

The XOR operation, the bitwise-and ($\&$) operation, and the addition (+) operation are used in the Phase 1 specification. A loop counter, i , and an array index temporary variable, j , are also employed.

One function, $Mk16$, is used in the definition of Phase 1. The function $Mk16$ constructs a 16-bit value from two 8-bit inputs as $Mk16(X,Y) = (256 \cdot X) + Y$.

Two steps make up the Phase 1 algorithm. The first step initializes $TTAK$ from TSC and TA . The second step uses an S-box to iteratively mix the keying material into the 80-bit $TTAK$. The second step sets the PHASE1_LOOP_COUNT to 8. See Figure 12-14.

```

Input: transmit address  $TA0 \dots TA5$ , Temporal Key  $TK0..TK15$ , and  $TSC0..TSC5$ 
Output: intermediate key  $TTAK0..TTAK4$ 
PHASE1-KEY-MIXING( $TA0 \dots TA5$ ,  $TK0..TK15$ ,  $TSC0..TSC5$ )
    PHASE1_STEP1:
         $TTAK0 \leftarrow MK16(TSC3, TSC2)$ 
         $TTAK1 \leftarrow MK16(TSC5, TSC4)$ 
         $TTAK2 \leftarrow MK16(TA1, TA0)$ 
         $TTAK3 \leftarrow MK16(TA3, TA2)$ 
         $TTAK4 \leftarrow MK16(TA5, TA4)$ 
    PHASE1_STEP2:
        for  $i = 0$  to PHASE1_LOOP_COUNT - 1
             $j \leftarrow 2 \cdot (i \& 1)$ 
             $TTAK0 \leftarrow TTAK0 + S[TTAK4 \oplus Mk16(TK1+j, TK0+j)]$ 
             $TTAK1 \leftarrow TTAK1 + S[TTAK0 \oplus Mk16(TK5+j, TK4+j)]$ 
             $TTAK2 \leftarrow TTAK2 + S[TTAK1 \oplus Mk16(TK9+j, TK8+j)]$ 
             $TTAK3 \leftarrow TTAK3 + S[TTAK2 \oplus Mk16(TK13+j, TK12+j)]$ 
             $TTAK4 \leftarrow TTAK4 + S[TTAK3 \oplus Mk16(TK1+j, TK0+j)] + i$ 

```

Figure 12-14—Phase 1 key mixing

NOTE 1—The TA is mixed into the temporal key in Phase 1 of the hash function. Implementations might achieve a significant performance improvement by caching the output of Phase 1. The Phase 1 output is the same for $2^{16} = 65\,536$ consecutive frames from the same temporal key and TA. Consider the simple case where a STA communicates only with an AP. The STA performs Phase 1 using its own address, and the $TTAK$ is used to protect traffic sent to the AP. The STA performs Phase 1 using the AP address, and it is used to unwrap traffic received from the AP.

NOTE 2—The cached $TTAK$ from Phase 1 needs to be updated when the lower 16 bits of the TSC wrap and the upper 32 bits need to be updated.

12.5.2.5.4 Phase 2 definition

The inputs to Phase 2 of the temporal key mixing function shall be the output of Phase 1 ($TTAK$) together with the temporal key and the TSC. The $TTAK$ is 80 bits in length. Only the 16 LSBs of the TSC are used in Phase 2. The temporal key is 128 bits. The output is the WEP seed, which is a per-frame key, and is 128 bits in length. The constructed WEP seed has an internal structure compliant with the WEP specification. In other words, the first 24 bits of the WEP seed shall be transmitted in plaintext as the WEP IV. As such, these 24 bits are used to convey lower 16 bits of the TSC from the sender (encryptor) to the receiver (decryptor). The rest of the TSC shall be conveyed in the Extended IV field. The temporal key and $TTAK$ values are represented as in Phase 1. The WEP seed is treated as an array of 8-bit values: $WEPSeed_0 \dots WEPSeed_{15}$. The TSC shall be treated as an array of 8-bit values: $TSC_0 \ TSC_1 \ TSC_2 \ TSC_3 \ TSC_4 \ TSC_5$.

The pseudocode specifying the Phase 2 mixing function employs one variable: PPK , which is 96 bits long. The PPK is represented as an array of 16-bit values: $PPK_0..PPK_5$. The pseudocode also employs a loop counter, i . As detailed in this subclause, the mapping from the 16-bit PPK values to the 8-bit $WEPseed$ values is explicitly little endian to match the endian architecture of the most common processors used for this application.

The XOR (\oplus) operation, the addition (+) operation, the AND (&) operation, the OR (\mid) operation, and the right bit shift ($>>$) operation are used in the specification of Phase 2. See Figure 12-15.

```

Input: intermediate key TTAK0...TTAK4, TK, and TKIP sequence counter TSC
Output: WEP Seed WEPSeed0...WEPSeed15
PHASE2-KEY-MIXING(TTAK0...TTAK4, TK0...TK15, TSC0...TSC5)
    PHASE2_STEP1:
        PPK0  $\leftarrow$  TTAK0
        PPK1  $\leftarrow$  TTAK1
        PPK2  $\leftarrow$  TTAK2
        PPK3  $\leftarrow$  TTAK3
        PPK4  $\leftarrow$  TTAK4
        PPK5  $\leftarrow$  TTAK4 + Mk16(TSC1, TSC0)
    PHASE2_STEP2:
        PPK0  $\leftarrow$  PPK0 + S[PPK5  $\oplus$  Mk16(TK1, TK0)]
        PPK1  $\leftarrow$  PPK1 + S[PPK0  $\oplus$  Mk16(TK3, TK2)]
        PPK2  $\leftarrow$  PPK2 + S[PPK1  $\oplus$  Mk16(TK5, TK4)]
        PPK3  $\leftarrow$  PPK3 + S[PPK2  $\oplus$  Mk16(TK7, TK6)]
        PPK4  $\leftarrow$  PPK4 + S[PPK3  $\oplus$  Mk16(TK9, TK8)]
        PPK5  $\leftarrow$  PPK5 + S[PPK4  $\oplus$  Mk16(TK11, TK10)]
        PPK0  $\leftarrow$  PPK0 + RotR1(PPK5  $\oplus$  Mk16(TK13, TK12))
        PPK1  $\leftarrow$  PPK1 + RotR1(PPK0  $\oplus$  Mk16(TK15, TK14))
        PPK2  $\leftarrow$  PPK2 + RotR1(PPK1)
        PPK3  $\leftarrow$  PPK3 + RotR1(PPK2)
        PPK4  $\leftarrow$  PPK4 + RotR1(PPK3)
        PPK5  $\leftarrow$  PPK5 + RotR1(PPK4)
    PHASE2_STEP3:
        WEPSeed0  $\leftarrow$  TSC1
        WEPSeed1  $\leftarrow$  (TSC1 | 0x20) & 0x7F
        WEPSeed2  $\leftarrow$  TSC0
        WEPSeed3  $\leftarrow$  Lo8((PPK5  $\oplus$  Mk16(TK1, TK0))  $>>$  1)
        for i = 0 to 5
            WEPSeed4+(2·i)  $\leftarrow$  Lo8(PPKi)
            WEPSeed5+(2·i)  $\leftarrow$  Hi8(PPKi)
        end
    return WEPSeed0...WEPSeed15

```

Figure 12-15—Phase 2 key mixing

The algorithm specification relies on four functions:

- The first function, *Lo8*, references the 8 LSBs of the 16-bit input value.
- The second function, *Hi8*, references the 8 MSBs of the 16-bit value.
- The third function, *RotR1*, rotates its 16-bit argument 1 bit to the right.
- The fourth function, *Mk16*, is already used in Phase 1, defined by $Mk16(X,Y) = (256 \cdot X) + Y$, and constructs a 16-bit output from two 8-bit inputs.

NOTE—The rotate and addition operations in STEP2 make Phase 2 particularly sensitive to the endian architecture of the processor, although the performance degradation due to running this algorithm on a big endian processor is expected to be minor.

Phase 2 comprises three steps:

- STEP1 makes a copy of *TTAK* and brings in the *TSC*.
- STEP2 is a 96-bit bijective mixing, employing an S-box.
- STEP3 brings in the last of the temporal key *TK* bits and assigns the 24-bit WEP IV value.

The WEP IV format carries 3 octets. STEP3 of Phase 2 determines the value of each of these three octets. The construction was selected to preclude the use of known ARC4 weak keys. The recipient can reconstruct

the 16 LSBs of the TSC used by the originator by concatenating the third and first octets, ignoring the second octet. The remaining 32 bits of the TSC are obtained from the Extended IV field.

12.5.2.6 TKIP replay protection procedures

TKIP implementations shall use the TSC field to defend against replay attacks by implementing the following rules:

- a) Each MPDU shall have a unique TKIP TSC value.
- b) Each transmitter shall maintain a single TSC (48-bit counter) for each PTKSA, GTKSA, and STKSA.
- c) The TSC shall be implemented as a 48-bit strictly increasing counter, initialized to 1 when the corresponding TKIP temporal key is initialized or refreshed.
- d) The WEP IV format carries the 16 LSBs of the 48-bit TSC, as defined by the TKIP mixing function (Phase 2, STEP3). The remainder of the TSC is carried in the Extended IV field.
- e) A receiver shall maintain a separate set of TKIP TSC replay counters for each PTKSA, GTKSA, and STKSA.
- f) TKIP replay detection takes place after the MIC verification and any reordering required by ack processing. Thus, a receiver shall delay advancing a TKIP TSC replay counter until an MSDU passes the MIC check, to prevent attackers from injecting MPDUs with valid ICVs and TSCs, but invalid MICs.

NOTE—This works because if an attacker modifies the TSC, then the encryption key is modified and hence both the ICV and MIC decrypt incorrectly, causing the received MPDU to be dropped.

- g) For each PTKSA, GTKSA, and STKSA, the receiver shall maintain a separate replay counter for each frame priority and shall use the TSC in a received frame to detect replayed frames, subject to the limitations on the number of supported replay counters indicated in the RSN Capabilities field, as described in 9.4.2.25. A replayed frame occurs when the TSC in a received frame is less than or equal to the current replay counter value for the frame's priority. A transmitter shall not reorder TKIP protected frames with different priorities without ensuring that the receiver supports the required number of replay counters. The transmitter shall not reorder TKIP protected frames within a replay counter, but may reorder TKIP protected frames across replay counters. One possible reason for reordering frames is the IEEE 802.11 MSDU priority.
- h) A receiver shall discard any MPDU that is received out of order and shall increment dot11RSNAStatsTKIPReplays for this key.
- i) For MSDUs sent using the block ack feature, reordering of received MSDUs according to the block ack receiver operation (described in 10.24.4) is performed prior to replay detection.

12.5.3 CTR with CBC-MAC protocol (CCMP)

12.5.3.1 General

Subclause 12.5.3 specifies all variants of CCMP, which provides data confidentiality, authentication, integrity, and replay protection. A non-DMG RSNA STA shall support CCMP-128.

CCMP is based on the CCM of the AES encryption algorithm. CCM combines CTR for data confidentiality and CBC-MAC for authentication and integrity. CCM protects the integrity of both the MPDU Data field and selected portions of the IEEE 802.11 MPDU header.

The AES algorithm is defined in FIPS PUB 197. AES processing used within CCMP uses AES with either a 128-bit key (CCMP-128) or a 256-bit key (CCMP-256).

CCM is defined in IETF RFC 3610. CCM is a generic mode that can be used with any block-oriented encryption algorithm. CCM has two parameters (M and L).

CCMP-128 uses the following values for the CCM parameters:

- $M = 8$; indicating that the MIC is 8 octets.
- $L = 2$; indicating that the Length field is 2 octets, which is sufficient to hold the length of the largest possible IEEE 802.11 MPDU, expressed in octets.

CCMP-256 uses the following values for the CCM parameters:

- $M = 16$; indicating that the MIC is 16 octets.
- $L = 2$; indicating that the Length field is 2 octets, which is sufficient to hold the length of the largest possible IEEE 802.11 MPDU, expressed in octets.

CCM requires a fresh temporal key for every session. CCM also requires a unique nonce value for each frame protected by a given temporal key, and CCMP uses a 48-bit packet number (PN) for this purpose. Reuse of a PN with the same temporal key voids all security guarantees.

Annex J provides a test vector for CCM.

When CCMP is selected as the RSN pairwise cipher and management frame protection is negotiated, individually addressed robust Management frames and the group addressed Management frames that receive “Group Addressed Privacy” as indicated in Table 9-47 shall be protected with CCMP.

12.5.3.2 CCMP MPDU format

Figure 12-16 depicts the MPDU when using CCMP.

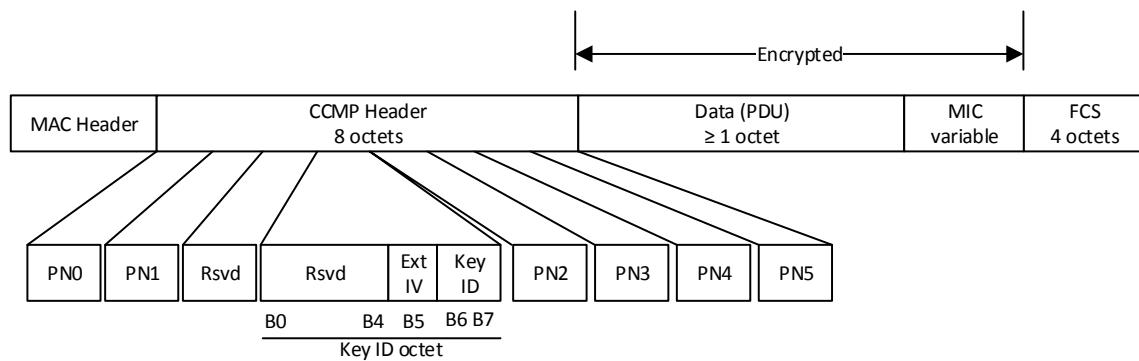

Figure 12-16—Expanded CCMP MPDU

CCMP-128 processing expands the original MPDU size by 16 octets, 8 octets for the CCMP Header field and 8 octets for the MIC field. CCMP-256 processing expands the original MPDU size by 24 octets, 8 octets for the CCMP Header field, and 16 octets for the MIC field. The CCMP Header field is constructed from the PN, ExtIV, and Key ID subfields. PN is a 48-bit PN represented as an array of 6 octets. PN5 is the most significant octet of the PN, and PN0 is the least significant. Note that CCMP does not use the WEP ICV.

The ExtIV subfield (bit 5) of the Key ID octet signals that the CCMP Header field extends the MPDU header by a total of 8 octets, compared to the 4 octets added to the MPDU header when WEP is used. The ExtIV bit (bit 5) is always set to 1 for CCMP.

Bits 6–7 of the Key ID octet are for the Key ID subfield.

12.5.3.3 CCMP cryptographic encapsulation

12.5.3.3.1 General

The CCMP cryptographic encapsulation process is depicted in Figure 12-17.

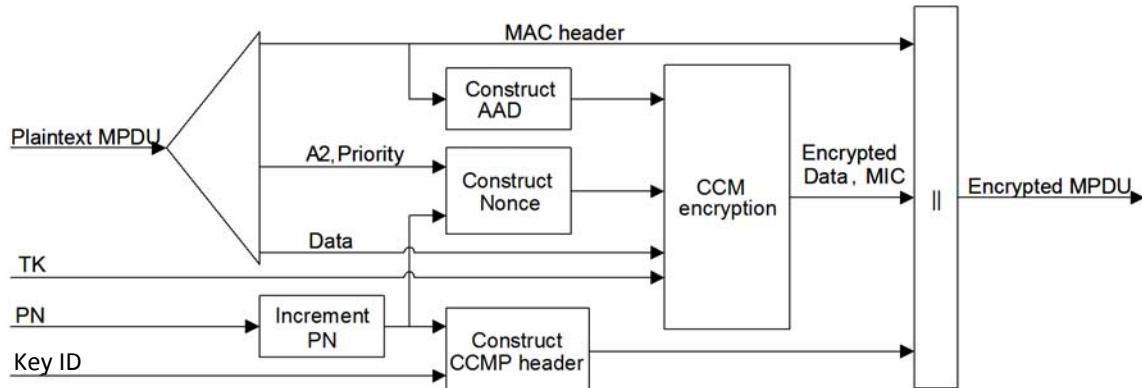

Figure 12-17—CCMP encapsulation block diagram

CCMP encrypts the Frame Body field of a plaintext MPDU and encapsulates the resulting cipher text using the following steps:

- Increment the PN, to obtain a fresh PN for each MPDU, so that the PN never repeats for the same temporal key. Note that retransmitted MPDUs are not modified on retransmission.
- Use the fields in the MPDU header to construct the additional authentication data (AAD) for CCM. The CCM algorithm provides integrity protection for the fields included in the AAD. MPDU header fields that may change when retransmitted are muted by being masked to 0 when calculating the AAD.
- Construct the CCM Nonce block from the PN, A2, and the priority value of the MPDU where A2 is MPDU Address 2. If the Type field of the Frame Control field is 10 (Data frame) and there is a QoS Control field present in the MPDU header, the priority value of the MPDU is equal to the value of the QC field TID (bits 0 to 3 of the QC field). If the Type field of the Frame Control field is 00 (Management frame), and the frame is a QMF, the priority value of the MPDU is equal to the value in the ACI subfield of the Sequence Number field. Otherwise, the priority value of the MPDU is equal to the fixed value 0.
- Place the new PN and the key identifier into the 8-octet CCMP header.
- Use the temporal key, AAD, nonce, and MPDU data to form the cipher text and MIC. This step is known as CCM originator processing.
- Form the encrypted MPDU by combining the original MPDU header, the CCMP header, the encrypted data and MIC, as described in 12.5.3.2.

The CCM reference describes the processing of the key, nonce, AAD, and data to produce the encrypted output. See 12.5.3.3.2 to 12.5.3.3.6 for details of the creation of the AAD and nonce from the MPDU and the associated MPDU-specific processing.

12.5.3.3.2 PN processing

The PN is incremented by a positive number for each MPDU. The PN shall be incremented in steps of 1 for constituent MPDUs of fragmented MSDUs and MMPDUs. The PN shall never repeat for a series of encrypted MPDUs using the same temporal key.

NOTE—When a group addressed MSDU is retransmitted using GCR, it is concealed from non-GCR capable STAs using the procedures described in 11.24.16.3.5. The MPDU containing this concealed A-MSDU has a different PN from the MPDU that contained the original transmission of the group addressed MSDU.

12.5.3.3 Construct AAD

The format of the AAD is shown in Figure 12-18.

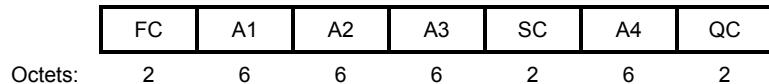

Figure 12-18—AAD construction

The length of the AAD varies depending on the presence or absence of the QC and A4 fields and is shown in Table 12-1.

Table 12-1—AAD length

| QC field | A4 field | AAD length (octets) |
|----------|----------|---------------------|
| Absent | Absent | 22 |
| Present | Absent | 24 |
| Absent | Present | 28 |
| Present | Present | 30 |

The AAD is constructed from the MPDU header. The AAD does not include the header Duration field, because the Duration field value might change due to normal IEEE 802.11 operation (e.g., a rate change during retransmission). The AAD includes neither the Duration/ID field nor the HT Control field because the contents of these fields might change during normal operation (e.g., due to a rate change preceding retransmission). The HT Control field might also be inserted or removed during normal operation (e.g., retransmission of an A-MPDU where the original A-MPDU included an MRQ that has already generated a response). For similar reasons, several subfields in the Frame Control field are masked to 0. AAD construction is performed as follows:

- a) FC – MPDU Frame Control field, with
 - 1) Subtype subfield (bits 4 5 6) in a Data frame masked to 0
 - 2) Retry subfield (bit 11) masked to 0
 - 3) Power Management subfield (bit 12) masked to 0
 - 4) More Data subfield (bit 13) masked to 0
 - 5) Protected Frame subfield (bit 14) always set to 1
 - 6) +HTC/Order subfield (bit 15) as follows:
 - i) Masked to 0 in all Data frames containing a QoS Control field
 - ii) Unmasked otherwise
- b) A1 – MPDU Address 1 field.
- c) A2 – MPDU Address 2 field.
- d) A3 – MPDU Address 3 field.

- e) SC – MPDU Sequence Control field, with the Sequence Number subfield (bits 4–15 of the Sequence Control field) masked to 0. The Fragment Number subfield is not modified.
- f) A4 – MPDU Address field, if present.
- g) QC – QoS Control field, if present, a 2-octet field that includes the MSDU priority. The QC TID is used in the construction of the AAD. When in a non-DMG BSS and both the STA and its peer have their SPP A-MSDU Capable fields equal to 1, bit 7 (the A-MSDU Present field) is used in the construction of the AAD. The remaining QC fields are masked to 0 for the AAD calculation (bits 4 to 6, bits 8 to 15, and bit 7 when either the STA or its peer has the SPP A-MSDU Capable field equal to 0). When in a DMG BSS, the A-MSDU Present bit 7 and A-MSDU Type bit 8 are used in the construction of the AAD, and the remaining QC fields are masked to 0 for the AAD calculation (bits 4 to 6, bits 9 to 15).

12.5.3.3.4 Construct CCM nonce

TheNonce field occupies 13 octets, and its structure is shown in Figure 12-19. The structure of the Nonce Flags subfield of the Nonce field is shown in Figure 12-20.

Figure 12-19—Nonce construction

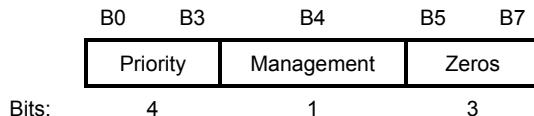

Figure 12-20—Nonce Flags subfield

The Nonce field has an internal structure of Nonce Flags || A2 || PN, where

- The Priority subfield of the Nonce Flags field shall be set to the priority value of the MPDU.
- When management frame protection is negotiated, the Management field of the Nonce Flags field shall be set to 1 if the Type field of the Frame Control field is 00 (Management frame); otherwise it shall be set to 0.
- Bits 5 to 7 of the Nonce Flags field shall be set to 0.
- MPDU address A2 field occupies octets 1–6. This shall be encoded with the octets ordered with A2 octet 0 at octet index 1 and A2 octet 5 at octet index 6.
- The PN field occupies octets 7–12. The octets of PN shall be ordered so that PN0 is at octet index 12 and PN5 is at octet index 7.

12.5.3.3.5 Construct CCMP header

The format of the 8-octet CCMP header is given in 12.5.3.2. The header encodes the PN, Key ID, and ExtIV field values used to encrypt the MPDU.

12.5.3.3.6 CCM originator processing

CCM is a generic authenticate-and-encrypt block cipher mode, and in this standard, CCM is used with the AES block cipher.

There are four inputs to CCM originator processing:

- Key*: the temporal key (16 octets).
- Nonce*: the nonce (13 octets) constructed as described in 12.5.3.3.4.
- Frame body*: the plaintext frame body of the MPDU.
- AAD*: the AAD (22–30 octets) constructed from the MPDU header as described in 12.5.3.3.3.

The CCM originator processing provides authentication and integrity of the frame body and the AAD as well as data confidentiality of the frame body. The output from the CCM originator processing consists of the encrypted data and an encrypted MIC (see Figure 12-16).

The PN values sequentially number each MPDU. Each transmitter shall maintain a single PN (48-bit counter) for each PTKSA, GTKSA, and STKSA. The PN shall be implemented as a 48-bit strictly increasing integer, initialized to 1 when the corresponding temporal key is initialized or refreshed.

A transmitter shall not use an IEEE 802.11 MSDU or A-MSDU priority if this would cause the total number of priorities used during the lifetime of the SA to exceed the number of replay counters supported by the receiver (for a pairwise SA) or all the receivers (for a group SA) for that SA. The transmitter shall not reorder CCMP protected frames that are transmitted to the same RA within a replay counter, but may reorder frames across replay counters. One possible reason for reordering frames is the IEEE 802.11 MSDU or A-MSDU priority.

The transmitter shall preserve the order of protected robust Management frames that are transmitted to the same DA without the QMF service. When the QMF service is used, the transmitter shall not reorder robust IQMFs within an AC when the frames are transmitted to the same RA.

A CCMP protected individually addressed robust Management frame shall be protected using the same TK as a Data frame.

12.5.3.4 CCMP decapsulation

12.5.3.4.1 General

Figure 12-21 depicts the CCMP decapsulation process.

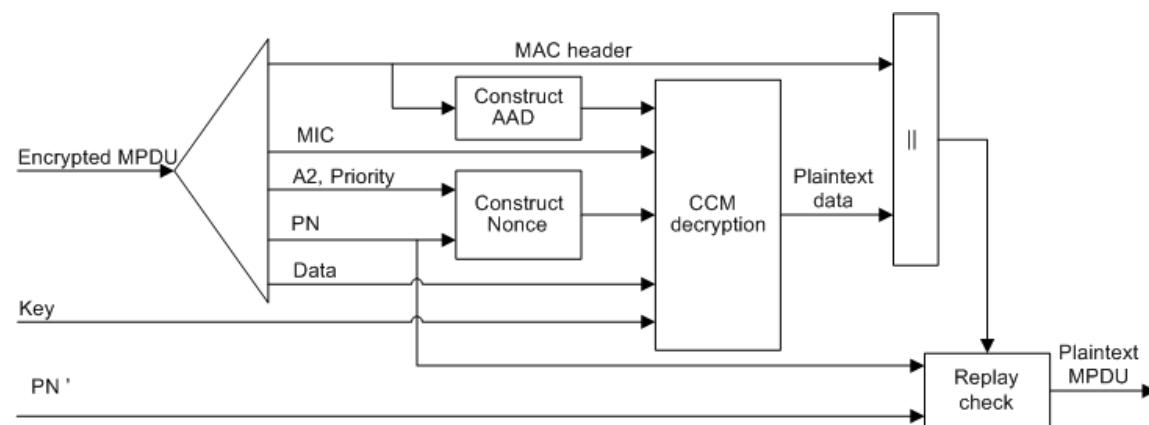

Figure 12-21—CCMP decapsulation block diagram

CCMP decrypts the Frame Body field of a cipher text MPDU and decapsulates a plaintext MPDU using the following steps:

- a) The encrypted MPDU is parsed to construct the AAD and nonce values.
- b) The AAD is formed from the MPDU header of the encrypted MPDU.
- c) The Nonce value is constructed from the A2, PN, and Nonce Flags fields.
- d) The MIC is extracted for use in the CCM integrity checking.
- e) The CCM recipient processing uses the temporal key, AAD, nonce, MIC, and MPDU cipher text data to recover the MPDU plaintext data as well as to check the integrity of the AAD and MPDU plaintext data.
- f) The received MPDU header and the MPDU plaintext data from the CCM recipient processing are concatenated to form a plaintext MPDU.
- g) The decryption processing prevents replay of MPDUs by validating that the PN in the MPDU is greater than the replay counter maintained for the session.

See 12.5.3.4.2 to 12.5.3.4.4 for details of this processing.

When the received frame is a CCMP protected individually addressed robust Management frame, contents of the MMPDU body after protection is removed shall be delivered to the SME via the MLME primitive designated for that MMPDU rather than through the MA-UNITDATA.indication primitive.

12.5.3.4.2 CCM recipient processing

CCM recipient processing uses the same parameters as CCM originator processing. A CCMP protected individually addressed robust Management frame shall use the same TK as a Data frame.

There are four inputs to CCM recipient processing:

- *Key*: the temporal key (16 octets).
- *Nonce*: the nonce (13 octets) constructed as described in 12.5.3.3.4.
- *Encrypted frame body*: the encrypted frame body from the received MPDU. The encrypted frame body includes the MIC.
- *AAD*: the AAD (22–30 octets) that is the canonical MPDU header as described in 12.5.3.3.3.

The CCM recipient processing checks the authentication and integrity of the frame body and the AAD as well as decrypting the frame body. The plaintext is returned only if the MIC check is successful.

There is one output from error-free CCM recipient processing:

- *Frame body*: the plaintext frame body, which is 8 octets (CCMP-128) or 16 octets (CCMP-256) smaller than the encrypted frame body.

12.5.3.4.3 Decrypted CCMP MPDU

The decapsulation process succeeds when the calculated MIC matches the MIC value obtained from decrypting the received encrypted MPDU. The original MPDU header is concatenated with the plaintext data resulting from the successful CCM recipient processing to create the plaintext MPDU.

12.5.3.4.4 PN and replay detection

To effect replay detection, the receiver extracts the PN from the CCMP header. See 12.5.3.2 for a description of how the PN is encoded in the CCMP header. The following processing rules are used to detect replay:

- a) The receiver shall maintain a separate set of replay counters for each PTKSA, GTKSA, and STKSA. The receiver initializes these replay counters to 0 when it resets the temporal key for a peer. The replay counter is set to the PN value of accepted CCMP MPDUs.
- b) For each PTKSA, GTKSA, and STKSA, the recipient shall maintain a separate replay counter for each TID, subject to the limitation of the number of supported replay counters indicated in the RSN Capabilities field (see 9.4.2.25), and shall use the PN from a received frame to detect replayed frames. A replayed frame occurs when the PN from a received frame is less than or equal to the current replay counter value for the frame's MSDU or A-MSDU priority and frame type.
- c) If dot11RSNAProtectedManagementFramesActivated is true, the recipient shall maintain a single replay counter for received individually addressed robust Management frames that are received with the To DS subfield equal to 0 and shall use the PN from the received frame to detect replays. If dot11QMFActivated is also true, the recipient shall maintain an additional replay counter for each ACI for received individually addressed robust Management frames that are received with the To DS subfield equal to 1. The QMF receiver shall use the ACI encoded in the Sequence Number field of the received frame to select the replay counter to use for the received frame, and shall use the PN from the received frame to detect replays. A replayed frame occurs when the PN from the frame is less than or equal to the current value of the management frame replay counter that corresponds to the ACI of the frame.
- d) The receiver shall discard any Data frame that is received with its PN less than or equal to the value of the replay counter that is associated with the TA and priority value of the received MPDU. The receiver shall discard MSDUs and MMPDUs whose constituent MPDU PN values are not incrementing in steps of 1. If dot11RSNAProtectedManagementFramesActivated is true, the receiver shall discard any individually addressed robust Management frame that is received with its PN less than or equal to the value of the replay counter associated with the TA of that individually addressed Management frame.
- e) When discarding a frame, the receiver shall increment by 1 dot11RSNAStatsCCMPReplays for Data frames or dot11RSNAStatsRobustMgmtCCMPReplays for robust Management frames.
- f) For MSDUs or A-MSDUs sent using the block ack feature, reordering of received MSDUs or A-MSDUs according to the block ack receiver operation (described in 10.24.4) is performed prior to replay detection.

12.5.4 Broadcast/multicast integrity protocol (BIP)

12.5.4.1 BIP overview

BIP provides data integrity and replay protection for group addressed robust Management frames after successful establishment of an IGTKSA (see 12.6.1.1.9).

BIP-CMAC-128 provides data integrity and replay protection, using AES-128 in CMAC Mode with a 128-bit integrity key and a CMAC TLen value of 128 (16 octets). BIP-CMAC-256 provides data integrity and replay protection, using AES-256 in CMAC Mode with a 256-bit integrity key and a CMAC TLen value of 128 (16 octets). NIST Special Publication 800-38B defines the CMAC algorithm, and NIST SP 800-38D defines the GMAC algorithm. BIP processing uses AES with a 128-bit or 256-bit integrity key and a CMAC TLen value of 128 (16 octets). The CMAC output for BIP-CMAC-256 is not truncated and shall be 128 bits (16 octets). The CMAC output for BIP-CMAC-128 is truncated to 64 bits:

MIC = Truncate-64(CMAC Output).

BIP-GCMP-128 uses AES with a 128-bit integrity key, and BIP-GCMP-256 uses AES with a 256-bit integrity key. The authentication tag for both BIP-GCMP-128 and BIP-GCMP-256 is not truncated and shall be 128 bits (16 octets).

BIP uses the IGTK to compute the MMPDU MIC. The authenticator shall distribute one new IGTK and IGTK PN (IPN) whenever it distributes a new GTK. The IGTK is identified by the MAC address of the transmitting STA plus an IGTK identifier that is encoded in the MME Key ID field.

12.5.4.2 BIP MMPDU format

The Management MIC element shall follow all of the other elements in the management frame body but precede the FCS. See 9.4.2.55 for the format of the Management MIC element. Figure 12-22 shows the BIP MMPDU.

Figure 12-22—BIP Encapsulation

12.5.4.3 BIP AAD construction

The BIP Additional Authentication Data (AAD) shall be constructed from the MPDU header. The Duration field in the AAD shall be masked to 0. The AAD construction shall use a copy of the IEEE 802.11 header without the SC field for the MPDU, with the following exceptions:

- a) FC—MPDU Frame Control field, with:
 - 1) Retry subfield (bit 11) masked to 0
 - 2) Power Management subfield (bit 12) masked to 0
 - 3) More Data subfield (bit 13) masked to 0
- b) A1—MPDU Address 1 field.
- c) A2—MPDU Address 2 field.
- d) A3—MPDU Address 3 field.

Figure 12-23 depicts the format of the AAD. The length of the AAD is 20 octets.

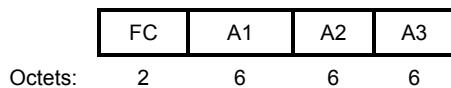

Figure 12-23—BIP AAD Construction

12.5.4.4 BIP replay protection

The MME Sequence Number field represents a sequence number whose length is 6 octets.

When management frame protection is negotiated, the receiver shall maintain a 48-bit replay counter for each IGTK. The receiver shall set the receive replay counter to the value of the IPN in the IGTK key data encapsulation (KDE) (see 12.7.2) provided by the Authenticator in either the 4-way handshake, FT 4-way handshake, FT handshake, or group key handshake. The transmitter shall maintain a single IPN for each IGTK. The IPN shall be implemented as a 48-bit strictly increasing integer, initialized to 1 when the corresponding IGTK is initialized. The transmitter may reinitialize the sequence counter when the IGTK is refreshed. See 12.5.4.5 and 12.5.4.6 for per packet BIP processing.

NOTE—When the IPN space is exhausted, the choices available to an implementation are to replace the IGTK or to end communications.

When dot11QMFAActivated is true, the receiver shall maintain an additional replay counter for each ACI for received group addressed robust Management frames that use QMF. The receiver shall use the ACI encoded in the Sequence Number field of received GQMFs protected by BIP to select the replay counter to use for the received frame, and shall use the IPN from the received frame to detect replays.

If `dot11RSNAProtectedManagementFramesActivated` is true and `dot11MeshSecurityActivated` is true, the recipient shall maintain a single replay counter for received group addressed robust Management frames that do not use the QMF service and shall use the PN from the received frame to detect replays. If `dot11QMFActivated` is also true, the recipient shall maintain an additional replay counter for each ACI for received group addressed robust Management frames that use the QMF service. The QMF receiver shall use the ACI encoded in the Sequence Number field of the received frame to select the replay counter to use for the received frame, and shall use the PN from the received frame to detect replays. A replayed frame occurs when the PN from the frame is less than or equal to the value of the management frame replay counter that corresponds to the ACI of the frame. The transmitter shall preserve the order of protected robust Management frames transmitted to the same DA without the QMF service. When the QMF service is used, the transmitter shall not reorder robust GQMFs within an AC when the frames are transmitted to the same RA.

12.5.4.5 BIP transmission

When a STA transmits a protected group addressed robust Management frame, it shall

- a) Select the IGTK currently active for transmission of frames to the intended group of recipients and construct the MME (see 9.4.2.55) with the MIC field masked to 0 and the Key ID field set to the corresponding IGTK Key ID value. If the frame is not a GQMF, the transmitting STA shall insert a strictly increasing integer into the MME IPN field. If the frame is a GQMF, then the transmitting STA shall maintain a 48-bit counter for use as the IPN, the counter shall be incremented for each GQMF until the two least significant bits of the counter match the ACI of the AC that is used to transmit the frame, and the counter value shall be inserted into the MME IPN field of the frame. For BIP-GMAC-128 and BIP-GMAC-256, the initialization vector passed to GMAC shall be a concatenation of Address 2 from the MAC header of the MPDU and the non-negative integer inserted into the MMP IPN field.
- b) Compute AAD as specified in 12.5.4.3.
- c) Compute an integrity value over the concatenation of AAD and the management frame body including MME, and insert the output into the MME MIC field. For BIP-CMAC-128, the integrity value is 64 bits and is computed using AES-128-CMAC; for BIP-CMAC-256, the integrity value is 128 bits and is computed using AES-256-CMAC; for BIP-GMAC-128, the integrity value is 128 bits and is computed using AES-128-GMAC; and, for BIP-GMAC-256, the integrity value is 128 bits and is computed using AES-256-GMAC.
- d) Compose the frame as the IEEE 802.11 header, management frame body, including MME, and FCS. The MME shall appear last in the frame body.
- e) Transmit the frame.

12.5.4.6 BIP reception

When a STA with management frame protection negotiated receives a group addressed robust Management frame protected by BIP-CMAC-128, BIP-CMAC-256, BIP-GMAC-128, or BIP-GMAC-256, it shall

- a) Identify the appropriate IGTK and associated state based on the MME Key ID field. If no such IGTK exists, silently drop the frame and terminate BIP processing for this reception.
- b) Perform replay protection on the received frame. The receiver shall interpret the MME IPN field as a 48-bit unsigned integer.
 - 1) If the frame is not a GQMF, the receiver shall compare this MME IPN integer value to the value of the receive replay counter for the IGTK identified by the MME Key ID field. If the integer value from the received MME IPN field is less than or equal to the replay counter value for this IGTK, the receiver shall discard the frame and increment the `dot11RSNAStatsCMACReplays` counter by 1.

- 2) If the frame is a GQMF, the receiver shall compare this MME IPN integer value to the value of the receive replay counter for the IGTK identified by the MME Key ID field and the AC represented by the value of the ACI subfield of the received frame. If the integer value from the received MME IPN field is less than or equal to the replay counter value for this IGTK and AC, the receiver shall discard the frame and increment the dot11RSNAStatsCMACReplays counter by 1.
- c) Compute AAD for this Management frame, as specified in 12.5.4.3. For BIP-GMAC-128 and BIP-GMAC-256, an initialization vector for GMAC is constructed as the concatenation of Address 2 from the MAC header of the MPDU and the 48-bit unsigned integer from the MME IPN field.
- d) Extract and save the received MIC value, and compute a verifier over the concatenation of AAD, the management frame body, and MME, with the MIC field masked to 0 in the MME. For BIP-CMAC-128, the integrity value is 64 bits and is computed using AES-128-CMAC; for BIP-CMAC-256, the integrity value is 128 bits and is computed using AES-256-CMAC; for BIP-GMAC-128, the integrity value is 128 bits and is computed using AES-128-GMAC; and, for BIP-GMAC-256, the integrity value is 128 bits and is computed using AES-256-GMAC. If the result does not match the received MIC value, then the receiver shall discard the frame, increment the dot11RSNAStatsBIP-MICErrors counter by 1, and terminate BIP processing for this reception.
- e) If the frame is not a GQMF, update the replay counter for the IGTK identified by the MME Key ID field with the integer value of the MME IPN field.
- f) If the frame is a GQMF, update the replay counter for the IGTK identified by the MME Key ID field and the AC represented by the value of the ACI subfield of the received frame with the integer value of the MME IPN field.

If management frame protection is negotiated, group addressed robust Management frames that are received without BIP protection shall be discarded.

12.5.5 GCM protocol (GCMP)

12.5.5.1 GCMP overview

Subclause 12.5.5 specifies the GCMP, which provides data confidentiality, authentication, integrity, and replay protection. A DMG RSNA STA shall support GCMP-128.

GCMP is based on the GCM of the AES encryption algorithm. GCM protects the integrity of both the MPDU Data field and selected portions of the MPDU header.

The AES algorithm is defined in FIPS PUB 197. All AES processing used within GCMP uses AES with a 128-bit key (GCMP-128) or a 256-bit key (GCMP-256).

GCM is defined in NIST Special Publication 800-38D. GCM is a generic mode that can be used with any block-oriented encryption algorithm.

GCM requires a fresh temporal key for every session. GCM also requires a unique nonce value for each frame protected by a given temporal key, and GCMP uses a 96-bit nonce that includes a 48-bit packet number (PN) for this purpose. Reuse of a PN with the same temporal key voids all security guarantees. GCMP uses a 128-bit MIC.

Annex J provides test vectors for GCM.

When GCMP is selected as the RSN pairwise cipher and management frame protection is negotiated, individually addressed robust Management frames and the group addressed Management frames that receive “Group Addressed Privacy” as indicated in Table 9-47 shall be protected with GCMP.

12.5.5.2 GCMP MPDU format

Figure 12-24 shows the MPDU format when using GCMP.

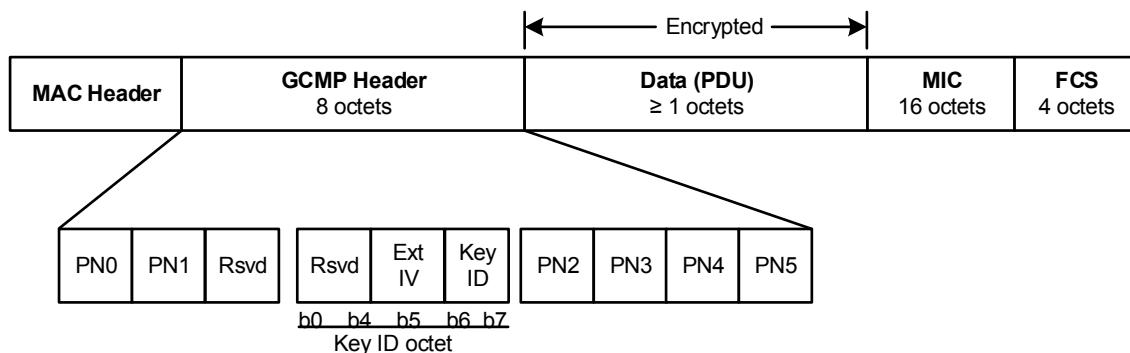

Figure 12-24—Expanded GCMP MPDU

GCMP processing expands the original MPDU size by 24 octets, 8 octets for the GCMP Header field and 16 octets for the MIC field. The GCMP Header field is constructed from the PN and Key ID subfields. The 48-bit PN is represented as an array of 6 octets. PN5 is the most significant octet of the PN, and PN0 is the least significant.

The ExtIV subfield (bit 5) of the Key ID octet is always set to 1 for GCMP.

Bits 6–7 of the Key ID octet are for the Key ID subfield. The remaining bits of the Key ID octet are reserved.

12.5.5.3 GCMP cryptographic encapsulation

12.5.5.3.1 General

The GCMP cryptographic encapsulation process is depicted in Figure 12-25.

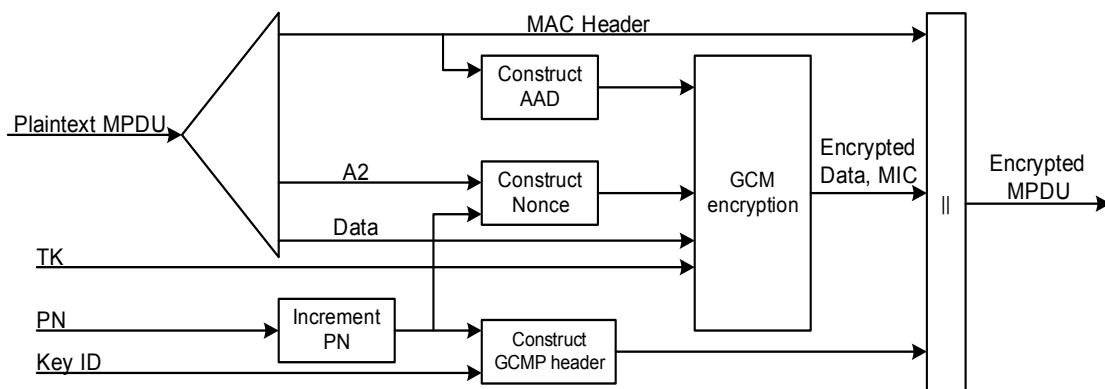

Figure 12-25—GCMP encapsulation block diagram

GCMP encrypts the Frame Body field of a plaintext MPDU and encapsulates the resulting cipher text using the following steps:

- Increment the PN, to obtain a fresh PN for each MPDU, so that the PN never repeats for the same temporal key.

NOTE—Retransmitted MPDUs are not modified on retransmission.

- b) Use the fields in the MPDU header to construct the additional authentication data (AAD) for GCM. The GCM algorithm provides integrity protection for the fields included in the AAD. MPDU header fields that may change when retransmitted are masked to 0 when calculating the AAD.
- c) Construct the GCM Nonce block from the PN and A2, where A2 is MPDU Address 2.
- d) Place the new PN and the key identifier into the 8-octet GCMP Header.
- e) Use the temporal key, AAD, nonce, and MPDU data to form the cipher text and MIC. This step is known as GCM originator processing.
- f) Form the encrypted MPDU by combining the original MPDU header, the GCMP header, the encrypted data and MIC, as described in 12.5.5.2.

The GCM reference describes the processing of the key, nonce, AAD, and data to produce the encrypted output. See 12.5.5.3.2 to 12.5.5.3.6 for details of the creation of the AAD and nonce from the MPDU and the associated MPDU-specific processing.

12.5.5.3.2 PN processing

The PN is incremented by a positive number for each MPDU. The PN shall be incremented in steps of 1 for constituent MPDUs of fragmented MSDUs and MMPDUs. The PN shall never repeat for a series of encrypted MPDUs using the same temporal key.

If the PN is larger than dot11PNExhaustionThreshold, an MLME-PN-EXHAUSTION.indication primitive shall be generated.

NOTE—When a group addressed MSDU is retransmitted using GCR, it is concealed from non-GCR capable STAs using the procedures described in 11.24.16.3.5. The MPDU containing this concealed A-MSDU has a different PN from the MPDU that contained the original transmission of the group addressed MSDU.

12.5.5.3.3 Construct AAD

The AAD construction is as defined in 12.5.3.3.3.

12.5.5.3.4 Construct GCM nonce

The Nonce field occupies 12 octets, and its structure is shown in Figure 12-26.

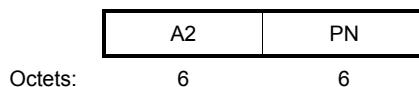

Figure 12-26—Nonce construction

The Nonce field has an internal structure of A2 || PN, where

- MPDU address A2 field occupies octets 0 to 5. This shall be encoded with the octets ordered with A2 octet 0 at octet index 0 and A2 octet 5 at octet index 5.
- The PN field occupies octets 6 to 11. The octets of PN shall be ordered so that PN0 is at octet index 11 and PN5 is at octet index 6.

12.5.5.3.5 Construct GCMP header

The format of the 8-octet GCMP Header is given in 12.5.5.2. The header encodes the PN and Key ID field values used to encrypt the MPDU.

12.5.5.3.6 GCM originator processing

GCM is a generic authenticate-and-encrypt block cipher mode, and in this standard, GCM is used with the AES block cipher.

There are four inputs to GCM originator processing:

- a) *Key*: the temporal key (16 octets).
- b) *Nonce*: the nonce (12 octets) constructed as described in 12.5.5.3.4.
- c) *Frame body*: the plaintext frame body of the MPDU.
- d) *AAD*: the AAD (22-30 octets) constructed from the MPDU header as described in 12.5.5.3.3.

The GCM originator processing provides authentication and integrity of the frame body and the AAD as well as data confidentiality of the frame body. The output from the GCM originator processing consists of the encrypted data and 16 additional octets of encrypted MIC (see Figure 12-24).

The PN values sequentially number each MPDU. Each transmitter shall maintain a single PN (48-bit counter) for each PTKSA, GTKSA, and STKSA. The PN shall be implemented as a 48-bit strictly increasing integer, initialized to 1 when the corresponding temporal key is initialized or refreshed.

A transmitter shall not use IEEE 802.11 MSDU or A-MSDU priorities without ensuring that the receiver supports the required number of replay counters. The transmitter shall not reorder GCMP protected frames that are transmitted to the same RA within a replay counter, but may reorder frames across replay counters. One possible reason for reordering frames is the IEEE 802.11 MSDU or A-MSDU priority.

The transmitter shall preserve the order of protected robust Management frames that are transmitted to the same DA without the QMF service. When the QMF service is used, the transmitter shall not reorder robust IQMFs within an AC when the frames are transmitted to the same RA.

A GCMP protected individually addressed robust Management frame shall be protected using the same TK as a Data frame.

12.5.5.4 GCMP decapsulation

12.5.5.4.1 General

Figure 12-27 shows the GCMP decapsulation process.

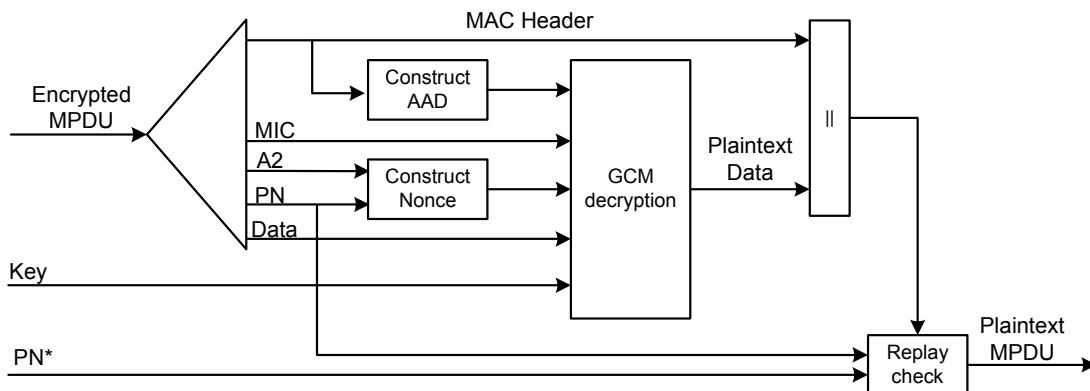

Figure 12-27—GCMP decapsulation block diagram

GCMP decrypts the Frame Body field of a cipher text MPDU and decapsulates a plaintext MPDU using the following steps:

- a) The encrypted MPDU is parsed to construct the AAD and nonce values.
- b) The AAD is formed from the MPDU header of the encrypted MPDU.
- c) The Nonce value is constructed from the A2 and PN fields.
- d) The MIC is extracted for use in the GCM integrity checking.
- e) The GCM recipient processing uses the temporal key, AAD, nonce, MIC, and MPDU cipher text data to recover the MPDU plaintext data as well as to check the integrity of the AAD and MPDU plaintext data.
- f) The received MPDU header and the MPDU plaintext data from the GCM recipient processing are concatenated to form a plaintext MPDU.
- g) The decryption processing prevents replay of MPDUs by validating that the PN in the MPDU is greater than the replay counter maintained for the session.

See 12.5.5.4.2 to 12.5.5.4.4 for details of this processing.

When the received frame is a GCMP protected individually addressed robust Management frame, the contents of the MMPDU body after protection is removed and shall be delivered to the SME via the MLME primitive designated for that MMPDU rather than through the MA-UNITDATA.indication primitive.

12.5.5.4.2 GCM recipient processing

GCM recipient processing shall use the same parameters as GCM originator processing. A GCMP protected individually addressed robust Management frame shall use the same TK as a Data frame.

There are four inputs to GCM recipient processing:

- *Key*: the temporal key (16 octets).
- *Nonce*: the nonce (12 octets) constructed as described in 12.5.5.3.4.
- *Encrypted frame body*: the encrypted frame body from the received MPDU. The encrypted frame body includes a 16-octet MIC.
- *AAD*: the AAD (22-30 octets) that is the canonical MPDU header as described in 12.5.5.3.3.

The GCM recipient processing checks the authentication and integrity of the frame body and the AAD as well as decrypting the frame body. The plaintext is returned only if the MIC check is successful.

There is one output from error-free GCM recipient processing:

- *Frame body*: the plaintext frame body, which is 16 octets smaller than the encrypted frame body.

12.5.5.4.3 Decrypted GCMP MPDU

The decapsulation process succeeds when the calculated MIC matches the MIC value obtained from decrypting the received encrypted MPDU. The original MPDU header is concatenated with the plaintext data resulting from the successful GCM recipient processing to create the plaintext MPDU.

12.5.5.4.4 PN and replay detection

To effect replay detection, the receiver extracts the PN from the GCMP header. See 12.5.5.2 for a description of how the PN is encoded in the GCMP header. The following processing rules are used to detect replay:

- a) The receiver shall maintain a separate set of replay counters for each PTKSA, GTKSA, and STKSA. The receiver initializes these replay counters to 0 when it resets the temporal key for a peer. The replay counter is set to the PN value of accepted GCMP MPDUs.
- b) For each PTKSA, GTKSA, and STKSA, the recipient shall maintain a separate replay counter for each TID, subject to the limitation of the number of supported replay counters indicated in the RSN Capabilities field (see 9.4.2.25), and shall use the PN from a received frame to detect replayed frames. A replayed frame occurs when the PN from a received frame is less than or equal to the current replay counter value for the frame's MSDU or A-MSDU priority and frame type.
- c) If dot11RSNAProtectedManagementFramesActivated is true, the recipient shall maintain a single replay counter for received individually addressed robust Management frames that are received with the To DS subfield equal to 0 and shall use the PN from the received frame to detect replays. If dot11QMFActivated is also true, the recipient shall maintain an additional replay counter for each ACI for received individually addressed robust Management frames that are received with the To DS subfield equal to 1. The QMF receiver shall use the ACI encoded in the Sequence Number field of the received frame to select the replay counter to use for the received frame, and shall use the PN from the received frame to detect replays. A replayed frame occurs when the PN from the frame is less than or equal to the current value of the management frame replay counter that corresponds to the ACI of the frame.
- d) The receiver shall discard any Data frame that is received with its PN less than or equal to the value of the replay counter that is associated with the TA and priority value of the received MPDU. The receiver shall discard MSDUs and MMPDUs whose constituent MPDU PN values are not incrementing in steps of 1. If dot11RSNAProtectedManagementFramesActivated is true, the receiver shall discard any individually addressed robust Management frame that is received with its PN less than or equal to the value of the replay counter associated with the TA of that individually addressed Management frame.
- e) When discarding a frame, the receiver shall increment by 1 dot11RSNAStatsGCMPReplays for Data frames or dot11RSNAStatsRobustMgmtGCMPReplays for robust Management frames.
- f) For MSDUs or A-MSDUs sent using the block ack feature, reordering of received MSDUs or A-MSDUs according to the block ack receiver operation (described in 10.24.4) is performed prior to replay detection.

12.6 RSNA security association management

12.6.1 Security associations

12.6.1.1 Security association definitions

12.6.1.1.1 General

IEEE Std 802.11 uses the notion of a security association to describe secure operation. Secure communications are possible only within the context of a security association, as this is the context providing the state—cryptographic keys, counters, sequence spaces, etc.—needed for correct operation of the IEEE 802.11 cipher suites.

A security association is a set of policy(ies) and key(s) used to protect information. The information in the security association is stored by each party of the security association, needs to be consistent among all parties, and needs to have an identity. The identity is a compact name of the key and other bits of security association information to fit into a table index or an MPDU. The following types of security associations are supported by an RSNA STA:

- PMKSA: A result of a successful IEEE 802.1X exchange, SAE authentication, or preshared PMK information. A PMKSA can be cached.

- PMK-R0 security association: A result of a successful FT initial mobility domain association.
- PMK-R1 security association: A result of a successful FT initial mobility domain association or FT authentication sequence.
- Mesh PMKSA: A result of successful completion of the active authentication protocol.
- PTKSA: A result of a successful 4-way handshake, FT 4-way handshake, or FT authentication sequence.
- Mesh TKSA: A result of a successful authenticated mesh peering exchange (AMPE).
- GTKSA: A result of a successful group key handshake, 4-way handshake, FT 4-way handshake, or FT authentication sequence.
- IGTKSA: A result of a successful group key handshake, successful 4-way handshake, FT 4-way handshake, or the Reassociation Response frame of the fast BSS transition protocol.
- Mesh GTKSA: A result of a successful AMPE or mesh group key handshake.
- SMKSA: A result of a successful initial SMK handshake.
- STKSA: A result of a successful 4-way STK handshake following the initial SMK handshake or subsequent rekeying.

In order to set up a security association to a peer STA, a SME that does not know the security policy of the peer should send a Probe Request frame to the peer STA to find its security policy before setting up a security association to the peer STA.

In order to set up a security association to a peer STA, a STA that received a 4-way handshake but does not know the security policy of the peer should send a Probe Request frame to the peer STA to find its security policy before setting up a security association to the peer STA.

12.6.1.1.2 PMKSA

When the PMKSA is the result of a successful IEEE 802.1X authentication, it is derived from the EAP authentication and authorization parameters provided by the AS. When the PMKSA is the result of a successful SAE authentication, it is generated as a result of the successful completion of the SAE exchange. This security association is bidirectional. In other words, both parties use the information in the security association for both sending and receiving. The PMKSA is created by the Supplicant's SME when the EAP authentication completes successfully or the PSK is configured. The PMKSA is created by the Authenticator's SME when the PMK is created from the keying information transferred from the AS, when IEEE 802.1X authentication is utilized, when the SAE exchange successfully completes, or when the PSK is configured. The PMKSA is used to create the PTKSA. PMKSAs have a certain lifetime. The PMKSA consists of the following:

- PMKID, as defined in 12.7.1.3. The PMKID identifies the security association.
- Authenticator's or peer's MAC address. For multi-band RSNA, the MAC address is associated with the operating band in use when the PMKSA is established.
- PMK.
- Lifetime, as defined in 12.7.1.3.
- AKMP.
- All authorization parameters specified by the AS or local configuration. This might include parameters such as the STA's authorized SSID.

12.6.1.1.3 PMK-R0 security association

The PMK-R0 security association is the result of a successful completion of the IEEE 802.1X authentication, SAE authentication, or use of PSK during the FT initial mobility domain association. This security association is bidirectional. It consists of the following:

- SSID
- Mobility domain identifier (MDID)
- PMK-R0
- R0KH-ID
- PMKR0Name
- S0KH-ID
- PMK-R0 lifetime
- Pairwise cipher suite selector
- All authorization parameters specified by the AS or local configuration

12.6.1.1.4 PMK-R1 security association

The PMK-R1 security association is the result of

- A successful completion of the IEEE 802.1X authentication, SAE authentication, or use of PSK during the FT initial mobility domain association or
- A successful completion of the authentication phase in the fast BSS transition to the target AP

This security association is bidirectional. It consists of the following:

- SSID
- MDID
- PMK-R1
- PMK-R1 lifetime
- PMKR1Name
- R1KH-ID
- R0KH-ID
- PMKR0Name
- S0KH-ID
- S1KH-ID
- Pairwise cipher suite selector
- All authorization parameters specified by the AS or local configuration

12.6.1.1.5 Mesh PMKSA

The mesh PMKSA is the result of successful completion of the active authentication protocol. This security association is bidirectional. The two authenticated parties use the information in the security association for both sending and receiving. The mesh PMKSA is created by the Mesh STA's SME when the active authentication protocol completes successfully with the peer mesh STA. The mesh PMKSA is used to create the mesh TKSA. Mesh PMKSAs have a certain lifetime. Mesh PMKSAs contain the following, and are identified by their PMKID.

- PMKID, as defined in 12.4.5.4
- Mesh STA's MAC address
- Peer mesh STA's MAC address
- PMK
- AEK, as defined in 14.5.7
- Lifetime, as defined in 12.7.1.3
- Selected AKM suite (see 9.4.2.25.3)

12.6.1.1.6 PTKSA

The PTKSA is a result of the 4-way handshake, FT 4-way handshake, FT protocol, or FT resource request protocol. This security association is also bidirectional. PTKSAs have the same lifetime as the PMKSA or PMK-R1 security Association, whichever comes first. Because the PTKSA is tied to the PMKSA or to a PMK-R1 security association, it only has the additional information from the 4-way handshake or FT Protocol authentication. For the PTKSA derived as a result of the 4-way handshake, there shall be only one PTKSA per band (see 12.6.19) with the same Supplicant and Authenticator MAC addresses. For the PTKSA derived as a result of an initial mobility domain association or fast BSS transition, there shall be only one PTKSA with the same STA's MAC address and BSSID.

During the 4-way handshake defined in 12.7.6.5 and the FT 4-way handshake defined in 13.4.2, there is state created between message 1 and message 3 of the handshake. This does not create a PTKSA until message 3 is validated by the Supplicant and message 4 is validated by the Authenticator.

During the FT authentication sequence defined in 13.8, the PTKSA is validated when message 3 is validated by the R1KH and message 4 is validated by the S1KH.

The PTKSA consists of the following:

- PTK
- Pairwise cipher suite selector
- Supplicant MAC address or STA's MAC address
- Authenticator MAC address or BSSID
- Key ID
- If FT key hierarchy is used,
 - R1KH-ID
 - S1KH-ID
 - PTKName

12.6.1.1.7 Mesh TKSA

The mesh TKSA is a result of the AMPE. This security association is also bidirectional. The mesh TKSA shall be deleted when the lifetime expires. The mesh TKSA contains the following:

- MTK, as defined in 14.5.7
- PMKID
- Local mesh STA MAC address
- Peer mesh STA MAC address
- Local Link ID
- Peer Link ID
- Local nonce
- Peer nonce
- Lifetime as defined in 12.6.16
- Pairwise cipher suite selector

12.6.1.1.8 GTKSA

The GTKSA results from a successful 4-way handshake, FT 4-way handshake, FT protocol, FT resource request protocol or the group key handshake and is unidirectional. In an infrastructure BSS, there is one GTKSA, used exclusively for encrypting group addressed MPDUs that are transmitted by the AP and for

decrypting group addressed transmissions that are received by the STAs. In an IBSS or in a PBSS, each STA defines its own GTKSA, which is used to encrypt its group addressed transmissions, and stores a separate GTKSA for each peer STA so that encrypted group addressed traffic received from other STAs may be decrypted. A GTKSA is created by the Supplicant’s SME when message 3 of the 4-way handshake is received, when message 1 of the group key handshake is received, or when the Reassociation Response frame of the FT handshake is received. The GTKSA is created by the Authenticator’s SME when the SME changes the GTK and has sent the GTK to all STAs with which it has a PTKSA. A GTKSA consists of the following:

- Direction vector (whether the GTK is used for transmit or receive).
- Group cipher suite selector.
- GTK.
- Authenticator MAC address.
- Key ID.
- All authorization parameters specified by local configuration. This might include parameters such as the STA’s authorized SSID.

When the GTK is used to encrypt individually addressed traffic (the selectable cipher suite is “Use group cipher suite”), the GTKSA is bidirectional.

12.6.1.1.9 IGTKSA

When management frame protection is enabled, a non-AP STA’s SME creates an IGTKSA when it receives a valid message 3 of the 4-way handshake or FT 4-way handshake, the Reassociation Response frame of the fast BSS transition protocol with a status code indicating success, a Mesh Peering Open Message of the Authenticated Mesh Peering Exchange (AMPE) protocol, or a valid message 1 of the group key handshake. The Authenticator’s SME creates an IGTKSA when it establishes or changes the IGTK with all STAs to which it has a valid PTKSA or mesh TKSA.

An IGTKSA consists of the following:

- Direction vector (whether the IGTK is used for transmit or receive)
- Key ID
- IGTK
- Authenticator MAC address

12.6.1.1.10 Mesh GTKSA

The mesh GTKSA results from a successful AMPE or mesh group key handshake and is unidirectional. In an MBSS, each mesh STA defines its own “transmit mesh GTKSA,” which is used to encrypt its group addressed transmissions. Also, each mesh STA stores a separate “receive mesh GTKSA” for each peer mesh STA so that encrypted group addressed traffic received from the peer mesh STAs may be decrypted.

A transmit mesh GTKSA is created by a mesh STA after the SME has changed the mesh GTK (MGTK) and the new MGTK has been sent to all peer mesh STAs. A receive mesh GTKSA is created by a mesh STA after successfully completing the AMPE in which a wrapped MGTK has been received, or after receiving a valid message 1 of the mesh group key handshake. The receive mesh GTKSA shall be deleted when the lifetime expires or a new receive mesh GTKSA is created with the same Key ID for the same MGTK source mesh STA. See 14.6.1.

The MGTK and the GTK shall be independently selected from a uniform distribution. The MGTK source mesh STA MAC address in the mesh GTKSA shall not be the same as the Authenticator MAC address in the GTKSA.

NOTE—The use of a distinct Transmit MGTK and ESS GTK with identical transmit MAC addresses is precluded by limitations on key rollover and reception by STAs in an infrastructure BSS (see 14.11.5 for collocated mesh STA rules). If the distinct MGTGs were to use different Key IDs, then rollover would be impossible. Since Key ID 0 is reserved for individually addressed frame transmission, there are at most three available Key IDs (only two if extended Key IDs for individually addressed frames are in use), and the different MGTGs would contend for the single remaining Key ID upon rollover. If the distinct MGTGs were to use the same Key IDs, then STAs would incorrectly attempt to decrypt mesh broadcast traffic using the ESS GTK, causing error counters (such as dot1RSNAStatsCCMPDecryptErrors) to continuously increment. (See 12.9.2.6 for a description of the procedure for receiving encrypted frames.)

The mesh GTKSA contains the following:

- MGTK
- MGTK source mesh STA MAC address (mesh STA that uses this GTK to encrypt transmissions)
- Group cipher suite selector
- Direction vector (whether this is a receive mesh GTKSA or transmit mesh GTKSA)
- Key Index

12.6.1.11 SMKSA

An SMKSA is the result of a successful SMK handshake by the initiator STA (described in 12.7.8 and 12.11). It is derived from parameters provided by the STAs and AP. This security association is bidirectional between the initiator and the peer STA. In other words, both parties use the information in the security association for both sending and receiving. The SMKSA is created as a result of a successful SMK handshake (see 12.7.8 and 12.11). The SMKSA is used to create the STKSA. The SMKSA consists of the following:

- SMKID, as defined in 12.7.8. The SMKID identifies the security association.
- BSSID
- Initiator MAC address
- Peer MAC address
- SMK
- Lifetime, as defined in 12.7.8.
- Pairwise cipher suite selector list, as proposed by initiator STA
- Pairwise cipher suite selector, as selected by peer STA

12.6.1.12 STKSA

The STKSA is a result of successful completion of the 4-way STK handshake. This security association is bidirectional between the initiator and the peer STAs. The STKSA is used to create session keys to protect this STSL. STKSAs have the same lifetime as the SMKSA or the STSL, whichever comes first. There shall be only one STKSA with the same initiator STA and peer MAC addresses at any one time. STKSA is created as a result of PeerKey handshake (see 12.7.8) or the AP PeerKey protocol (see 12.11). The STKSA consists of the following:

- STK
- Pairwise cipher suite selector
- Initiator MAC address
- Peer MAC address
- Key ID

12.6.1.2 TPKSA

The TPKSA results from a successful completion of the TPK handshake. This security association is bidirectional between the TDLS initiator STA and the TDLS responder STA. The TPKSA is used to create

session keys to protect this TDLS session. The TPKSA has the lifetime indicated in the TPK handshake or the lifetime of the TDLS direct link, whichever comes first.

The TPKSA consists of the following:

- MAC addresses of the TDLS initiator STA and the TDLS responder STA
- Pairwise cipher suite selector
- TPK Lifetime
- TPK
- Link Identifier

12.6.1.3 Security association life cycle

12.6.1.3.1 General

A STA can operate in an ESS, an IBSS, an MBSS, or a PBSS, and a security association has a distinct life cycle for each. A STA that operates OCB does not have a security association life cycle.

12.6.1.3.2 Security association in an ESS

In an ESS there are two cases:

- Initial contact between the STA and the ESS
- Roaming by the STA within the ESS

A STA and AP establish an initial security association via the following steps:

- a) The STA selects an authorized ESS by selecting among APs that advertise an appropriate SSID.
- b) The STA then performs IEEE 802.11 authentication followed by association to the chosen AP. Confirmation of security parameters takes place during association. A STA performing IEEE 802.1X authentication uses Open System authentication. A STA performing password-based authentication can use SAE authentication.

NOTE 1—It is possible for more than one PMKSA to exist. As an example, a second PMKSA might come into existence through PMKSA caching. A STA might leave the ESS and flush its cache. Before its PMKSA expires in the AP’s cache, the STA returns to the ESS and establishes a second PMKSA from the AP’s perspective.

NOTE 2—An attack altering the security parameters is detected by the key derivation procedure.

NOTE 3—IEEE 802.11 Open System authentication provides no security, but is included to maintain backward compatibility with the IEEE 802.11 state machine (see 11.3).

- c) SAE authentication provides mutual authentication and derivation of a PMK. If Open System authentication is chosen instead, the Authenticator or the Supplicant initiates IEEE 802.1X authentication. The EAP method used by IEEE Std 802.1X-2010 needs to support mutual authentication, as the STA needs assurance that the AP is a legitimate AP.

NOTE 1—Prior to the completion of IEEE 802.1X authentication and the installation of keys, the IEEE 802.1X Controlled Port in the AP blocks all Data frames. The IEEE 802.1X Controlled Port returns to the unauthorized state and blocks all Data frames before invocation of an MLME-DELETEKEYS.request primitive. The IEEE 802.1X Uncontrolled Port allows IEEE 802.1X frames to pass between the Supplicant and Authenticator. Although IEEE Std 802.1X-2010 does not require a Supplicant Controlled Port, this standard assumes that the Supplicant has a Controlled Port in order to provide the needed level of security. Supplicants without a Controlled Port compromise RSN security and are not used.

NOTE 2—Any secure network cannot support promiscuous association, e.g., an unsecured operation of IEEE Std 802.11. A trust relationship is needed between the STA and the AS of the targeted SSID prior to association and secure operation, in order for the association to be trustworthy. The reason is that an attacker can deploy a rogue AP just as easily as a legitimate network provider can deploy a legitimate AP, so some sort of prior relationship is necessary to establish credentials between the ESS and the STA.

- d) The last step is key management. The authentication process, whether SAE authentication utilizing Authentication frames or IEEE 802.1X authentication utilizing Data frames post association, creates cryptographic keys shared between the cryptographic endpoints—the AP and STA, or the IEEE 802.1X AS and the STA, when using SAE or IEEE Std 802.1X, respectively. When using IEEE Std 802.1X, the AS transfers these keys to the AP, and the AP and STA uses one of the key confirmation handshakes, e.g., the 4-way handshake or FT 4-way handshake, to complete security association establishment. When using SAE authentication there is no AS and therefore no key transfer; the 4-way handshake is performed directly between the AP and STA. The key confirmation handshake indicates when the link has been secured by the keys and is ready to allow normal data traffic and protected robust Management frames.

When FT is not enabled, a STA roaming within an ESS establishes a new PMKSA by one of the four schemes:

- In the case of (re)association followed by IEEE 802.1X or PSK authentication, the STA repeats the same actions as for an initial contact association, but its Supplicant also deletes the PTKSA when it roams from the old AP. The Supplicant also deletes the PTKSA when it disassociates/deauthenticates from all BSSIDs in the ESS.
- In the case of SAE authentication followed by (re)association, the STA repeats the same actions as for initial contact association, but the non-AP STA also deletes the PTKSA when it roams from the old AP. Note that a STA can take advantage of the fact that it can perform SAE authentication to multiple APs while maintaining a single association with one AP, and then use any of the PMKSAs created during authentication to effect a fast BSS transition.
- A STA (AP) can cache PMKSAs for APs (STAs) in the ESS to which it has previously performed a full IEEE 802.1X authentication or SAE authentication. If a STA wishes to roam to an AP for which it has cached one or more PMKSAs, it can include one or more PMKIDs in the RSNE of its (Re)Association Request frame. An AP that has retained the PMK for one or more of the PMKIDs can proceed with the 4-way handshake. The AP shall include the PMKID of the selected PMKSA in message 1 of the 4-way handshake. If none of the PMKIDs of the cached PMKSAs matches any of the supplied PMKIDs, or if the AKM of the cached PMKSA differs from that offered in the (Re)Association Request, then the Authenticator, in the case of Open System authentication, shall perform another IEEE 802.1X authentication and, in the case of SAE authentication, shall transmit a Deauthentication frame to the STA. Similarly, if the STA fails to send a PMKID, the STA and AP need to perform a full IEEE 802.1X authentication.
- A STA already associated with the ESS can request its IEEE 802.1X Supplicant to authenticate with a new AP before associating to that new AP. The normal operation of the DS via the old AP provides the communication between the STA and the new AP. The SME delays reassociation with the new AP until IEEE 802.1X authentication completes via the DS. If IEEE 802.1X authentication completes successfully, then PMKSAs shared between the new AP and the STA are cached, thereby enabling the possible usage of reassociation without requiring a subsequent full IEEE 802.1X authentication procedure.

The MLME-DELETEKEYS.request primitive deletes the temporal key(s) established for the security association so that they cannot be used to protect subsequent IEEE 802.11 traffic. An SME uses this primitive when it deletes a PTKSA, GTKSA, or IGTKSA.

12.6.1.3.3 Security association in an IBSS

In an IBSS utilizing IEEE 802.11 Open System authentication and IEEE Std 802.1X, when a STA's SME establishes a security association with a peer STA, it creates both an IEEE 802.1X Supplicant and Authenticator for the peer. A STA in such an IBSS might also receive IEEE 802.1X messages from a previously unknown MAC address.

In an IBSS utilizing IEEE 802.11 SAE authentication, a STA creates a security association for a peer upon successful SAE authentication.

Any IBSS STA may decline to form a security association with a STA joining the IBSS. An attempt to form a security association may also fail because, for example, the peer uses a different PSK or password from what the STA expects.

In an IBSS each STA defines its own group key, i.e., GTK, to secure its group addressed transmissions. Each STA shall use either the 4-way handshake or the group key handshake to distribute its transmit GTK to its new peer STA. When the STA generates a new GTK, it also uses the group key handshake to distribute the new GTK to each established peer.

12.6.1.3.4 Security association in an MBSS

In order to create a secure peering, mesh STAs first authenticate each other and create a mesh PMKSA. This can be done using either SAE or IEEE Std 802.1X. A mesh STA shall support SAE authentication (see 12.4). A mesh STA may support IEEE 802.1X authentication (see 4.10).

When dot11MeshActiveAuthenticationProtocol is sae (1), the scanning mesh STA shall initiate SAE to the candidate mesh STA. If SAE terminates unsuccessfully, the scanning mesh STA shall terminate the peering establishment procedure. Otherwise, the PMK that results from successful SAE authentication shall be used to create a mesh PMKSA.

When dot11MeshActiveAuthenticationProtocol is ieee8021x (2), then the scanning mesh STA shall initiate the MPM protocol to establish a peering. If the MPM protocol fails then the scanning mesh STA shall terminate the peering establishment procedure. Otherwise, IEEE 802.1X authentication shall be performed between the two peers according to the following:

- If only one mesh STA has the Connected to AS field set to 1, that STA shall act as the IEEE 802.1X Authenticator and the other STA shall act as the IEEE 802.1X Supplicant;
- If both mesh STAs have the Connected to AS field set to 1, then the mesh STA with the higher MAC address shall act as the IEEE 802.1X Authenticator and the other mesh STA shall act as the IEEE 802.1X Supplicant (see 12.7.1 for MAC address comparison).

If IEEE 802.1X authentication fails, the peering establishment procedure shall be terminated and the peering established between the two mesh STAs shall be closed. Otherwise, the peering established between the two mesh STAs shall be closed and a mesh PMKSA shall be created using the PMK that resulted from the successful IEEE 802.1X authentication.

12.6.1.3.5 Security association in a PBSS

A STA and a peer establish an initial security association via the following steps:

- The STA selects an authorized PBSS by identifying a peer from a DMG Beacon, Announce, Probe Response, or Information Response frames.
- A STA may associate with a peer if the peer is a PCP.
- If authentication is required, the STA or the peer initiates IEEE 802.1X authentication. The EAP method used by IEEE Std 802.1X-2010 shall support mutual authentication.
- The last step is key management. The authentication process creates cryptographic keys shared between the IEEE 802.1X AS and the STA. The AS transfers these keys to the peer and the peer and the STA use one of the key confirmation handshakes, e.g., the 4-way handshake or FT 4-way handshake, to complete security association establishment. The key confirmation handshake indicates when the link has been secured by the keys and is ready to allow data traffic and protected robust Management frames.

12.6.2 RSNA selection

A STA prepared to establish RSNA shall advertise its capabilities by including the RSNE in Beacon, Information Response, and Probe Response frames and may also include the RSNE in DMG Beacon and Announce frames. The included RSNE shall specify all of the authentication and cipher suites enabled by the STA's policy. A STA shall not advertise any authentication or cipher suite that is not enabled.

The SME shall utilize the MLME-SCAN.request primitive to identify neighboring STAs that assert robust security and advertise an SSID identifying an authorized ESS, PBSS, or IBSS. A STA may decline to communicate with STAs that fail to advertise an RSNE in their Beacon, Information Response, and Probe Response frames or that do not advertise an authorized SSID. A STA may also decline to communicate with other STAs that do not advertise authorized authentication and cipher suites within their RSNEs.

A STA shall advertise the same RSNE in its Beacon, DMG Beacon, Announce, Information Response, and Probe Response frames.

NOTE—Whether a STA with robust security enabled attempts to communicate with a STA that does not include the RSNE is a matter of policy.

A STA shall observe the following rules when processing an RSNE:

- A STA shall advertise the highest version it supports.
- A STA shall request the highest Version field value it supports that is less than or equal to the version advertised by the peer STA.
- Two peer STAs without overlapping supported Version field values shall not use RSNA methods to secure their communication.
- A STA shall ignore suite selectors that it does not recognize.

12.6.3 RSNA policy selection in an infrastructure BSS

RSNA policy selection in an infrastructure BSS utilizes the normal IEEE 802.11 association procedure. RSNA policy selection is performed by the associating STA. The STA does this by including an RSNE in its (Re)Association Requests.

In an RSN, an AP shall not associate with pre-RSNA STAs, i.e., with STAs that fail to include the RSNE in the (Re)Association Request frame.

An SME initiating an association shall insert an RSNE into its (Re)Association Request via the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive, when the targeted AP indicates RSNA support. The initiating STA's RSNE shall include one authentication and pairwise cipher suite from among those advertised by the targeted AP in its Beacon and Probe Response frames. It shall also specify the group cipher suite specified by the targeted AP. If at least one RSNE field from the AP's RSNE fails to overlap with any value the STA supports, the STA shall decline to associate with that AP. An HT STA shall eliminate TKIP as a choice for the pairwise cipher suite if CCMP is advertised by the AP or if the AP included an HT Capabilities element in its Beacon and Probe Response frames. The elimination of TKIP as a choice for the pairwise cipher suite may result in a lack of overlap of the remaining pairwise cipher suite choices, in which case the STA shall decline to create an RSN association with that AP.

If an RSNA-capable AP receives a (Re)Association Request frame that includes an RSNE and if it chooses to accept the association as a secure association, then it shall use the authentication and pairwise cipher suites in the (Re)Association Request frame, unless the AP includes an optional second RSNE in message 3 of the 4-way handshake. If the second RSNE is supplied in message 3, then the pairwise cipher suite used by the security association, if established, shall be the pairwise cipher from the second RSNE.

In order to accommodate local security policy, a STA may choose not to associate with an AP that does not support any pairwise cipher suites. An AP may indicate that it does not support any pairwise keys by advertising 00-0F-AC:0 (Use group cipher suite) as the pairwise cipher suite selector.

NOTE—When an ESS uses PSKs, STAs negotiate a pairwise cipher. However, any STA in the ESS can derive the pairwise keys of any other that uses the same PSK by capturing the first two messages of the 4-way handshake. This provides malicious insiders with the ability to eavesdrop as well as the ability to establish a man-in-the-middle attack.

An RSNA-enabled AP shall use Table 12-2 and the values of the Management Frame Protection Capable (MFPC) and Management Frame Protection Required (MFPR) bits advertised in the RSNEs to determine if it may associate with a non-AP STA. An RSNA enabled non-AP STA shall use Table 12-2 and the values of the Management Frame Protection Capable and Management Frame Protection Required bits advertised in the RSNEs to determine if it may associate with an AP. Management frame protection is enabled when dot11RSNAProtectedManagementFramesActivated is set to 1. Management frame protection is negotiated when an AP and non-AP STA set the Management Frame Protection Capable field to 1 in their respective RSNEs in the (re)association procedure, and both parties confirm the Management Frame Protection Capable bit set to 1 in the 4-way handshake, FT 4-way handshake, or the FT fast BSS transition protocol.

Table 12-2—Robust management frame selection in an infrastructure BSS

| AP MFPC | AP MFPR | STA MFPC | STA MFPR | AP action | STA action |
|---------|---------|----------|----------|--|--|
| 0 | 0 | 0 | 0 | The AP may associate with the STA | The STA may associate with the AP |
| 1 | 0 | 0 | 0 | The AP may associate with the STA | The STA may associate with the AP |
| 1 | 0 or 1 | 1 | 0 or 1 | The AP may associate with the STA | The STA may associate with the AP |
| 1 | 1 | 0 | 0 | The AP shall reject associations from the STA with the Status Code ROBUST MANAGEMENT_POLICY_VIOLATION | The STA shall not associate with the AP |
| 0 | 0 | 1 | 1 | No action | The STA shall not try to associate with the AP |
| 0 | 0 | 1 | 0 | The AP may associate with the STA | The STA may associate with the AP |
| 1 | 0 or 1 | 0 | 1 | The STA advertises an invalid setting. The AP shall reject associations from the STA with the Status Code ROBUST MANAGEMENT_POLICY_VIOLATION | The STA shall not try to associate with the AP |
| 0 | 1 | 1 | 0 or 1 | No action | The AP advertises an invalid setting. The STA shall not try to associate with the AP |

12.6.4 TSN policy selection in an infrastructure BSS

In a TSN, an RSNA STA shall include the RSNE in its (Re)Association Requests.

An RSNA-capable AP configured to operate in a TSN shall include the RSNE and may associate with both RSNA and pre-RSNA STAs. In other words, an RSNA-capable AP shall respond to an associating STA that includes the RSNE just as in an RSN.

If an AP operating within a TSN receives a (Re)Association Request frame without an RSNE, its IEEE 802.1X Controlled Port shall initially be blocked. The SME shall unblock the IEEE 802.1X Controlled Port when WEP has been enabled.

12.6.5 RSNA policy selection in an IBSS and for DLS

In an IBSS all STAs use a single group cipher suite, and all STAs support a common subset of pairwise cipher suites. However, the SMEs of any pair of non-HT STAs may negotiate to use any common pairwise cipher suite they both support. Each STA shall include the group cipher suite and its list of pairwise cipher suites in its Beacon and Probe Response frames. Two STAs shall not establish a PMKSA unless they have advertised the same group cipher suite. Similarly, the two STAs shall not establish a PMKSA if the STAs have advertised disjoint sets of pairwise cipher suites.

An HT STA that is in an IBSS or that is transmitting frames through a direct link shall eliminate TKIP as a choice for the pairwise cipher suite if CCMP is advertised by the other STA or if the other STA included an HT Capabilities element in any of its Beacon, Probe Response, DLS Request, or DLS Response frames.

NOTE—The elimination of TKIP as a choice for the pairwise cipher suite might result in a lack of overlap of the remaining pairwise cipher suite choices, in which case the STAs do not exchange encrypted frames.

In order to set up a security association with a peer STA, the SME of an IBSS STA that does not know the peer’s policy needs first to obtain the peer’s security policy using a Probe Request frame. The SME entities of the two STAs select the pairwise cipher suites using one of the 4-way handshakes. The SMEs of each pair of STAs within an IBSS may use the EAPOL-Key 4-way handshake to select a pairwise cipher suite. As specified in 12.7.2, message 2 and message 3 of the 4-way handshake convey an RSNE. The message 2 RSNE includes the selected pairwise cipher suite, and message 3 includes the RSNE that the STA would send in a Probe Response frame.

If the 4-way handshake is successfully completed, then the pair of STAs shall use the pairwise cipher suite specified in message 2 of the 4-way handshake initiated by the Authenticator STA with the higher MAC address (see 12.7.1).

The SME shall check that the group cipher suite and AKMP match those in the Beacon and Probe Response frames for the IBSS.

NOTE 1—The RSNEs in message 2 and message 3 are not the same as in the Beacon frame. The group cipher and AKMP are the same, but the pairwise ciphers might differ because Beacon frames from different STAs might advertise different pairwise ciphers. Thus, IBSS STAs use the same AKM suite and group cipher, while different pairwise ciphers might be used between STA pairs.

NOTE 2—When an IBSS uses PSKs, STAs can negotiate a pairwise cipher. However, any STA in the IBSS can derive the PTKs of any other that uses the same PSK by capturing the first two messages of the 4-way handshake. This provides malicious insiders with the ability to eavesdrop as well as the ability to establish a man-in-the-middle attack.

To establish a connection with a peer STA, an RSNA enabled STA that implements management frame protection shall use Table 12-3 and the MFPC and MFPR values advertised in the RSNEs exchanged in the 4-way handshake initiated by the Authenticator of the STA with the larger MAC address to determine if the communication is allowed. Management frame protection is enabled when dot11RSNAProtectedManagementFramesActivated is set to 1. The STAs negotiate protection of Management frames when the both STAs set the Management Frame Protection Capable subfield to 1 during the 4-way handshake.

Table 12-3—Robust management frame selection in an IBSS

| MFPC | MFPR | Peer STA MFPC | Peer STA MFPR | STA action |
|-------------|-------------|----------------------|----------------------|--|
| 0 | 0 | 0 | 0 | The STA may exchange data with the peer STA. |
| 1 | 0 | 0 | 0 | The STA may exchange data with the peer STA. |
| 1 | 0 or 1 | 1 | 0 or 1 | The STA may exchange data with the peer STA. |
| 1 | 1 | 0 | 0 | The STA shall not exchange data with the peer STA and shall reject security association attempts from the peer STA with the Status Code ROBUST_MANAGEMENT_POLICY_VIOLATION. |
| 0 | 0 | 1 | 1 | The STA shall not exchange data with the peer STA and shall reject security association attempts from the peer STA with the Status Code ROBUST_MANAGEMENT_POLICY_VIOLATION. |
| 0 | 0 | 1 | 0 | The STA may establish a security association with the peer STA. |
| 1 | 0 or 1 | 0 | 1 | The STA shall not establish a security association with the peer STA and shall reject security association attempts from the peer STA with the Status Code ROBUST_MANAGEMENT_POLICY_VIOLATION because the peer STA is advertising an invalid setting. The STA shall not exchange data with the peer STA. |
| 0 | 1 | 1 | 0 or 1 | The peer STA shall not establish a security association with the peer STA and shall reject security association attempts from the STA with the Status Code ROBUST_MANAGEMENT_POLICY_VIOLATION because the STA is advertising an invalid setting. |

12.6.6 TSN policy selection in an IBSS

Pre-RSNA STAs generate Beacon and Probe Response frames without an RSNE and ignore the RSNE because it is unknown to them. This allows an RSNA STA to identify the pre-RSNA STAs from which it has received Beacon and Probe Response frames.

If an RSNA STA's SME instead identifies a possible IBSS member on the basis of a received group addressed message, via MLME-PROTECTEDFRAMEDROPPED.indication primitive, it cannot identify the peer's security policy directly. The SME might attempt to obtain the peer STA's security policy via a Probe Request frame.

12.6.7 RSNA policy selection in an MBSS

RSNA policy is advertised in Beacon frames and Probe Response frames. A mesh STA identifies a candidate peer by parsing its neighbor STA's Beacon frames and Probe Response frames (see 14.2). An HT mesh STA shall eliminate TKIP as a choice for the pairwise cipher suite if CCMP is advertised by the peer or if the peer included an HT Capabilities element in any of its Beacon or Probe Response frames.

All mesh STAs in an MBSS use the same group cipher suite. Mesh STAs establish authenticated peerings with each other using the AMPE protocol (see 14.5). In AMPE, mesh STAs negotiate a pairwise cipher suite, and establish a mesh TKSA, to protect individually addressed frames and state a group cipher suite and establish a mesh GTKSA to process incoming group addressed frames from a peer.

The AMPE performs key confirmation of a secret, authenticated, and shared PMK derived by an authenticated key management protocol (see 12.4) and derives pairwise symmetric keys.

12.6.8 RSNA policy selection in a PBSS

RSNA policy selection in a PBSS utilizes the association procedure (11.3.1) if the initiating STA chooses to associate with a PCP. RSNA policy selection is performed by the associating STA. The STA does this by including an RSNE in its (Re)Association Requests.

The STA follows the procedures in 12.5.3 to select RSNA policy with the PCP, with the PCP taking the role of the AP. If the initiating STA chooses not to associate with a peer in a PBSS, it follows the procedures in 12.5.5 to select RSNA policy with the peer.

12.6.9 RSN management of the IEEE 802.1X Controlled Port

When the policy selection process chooses IEEE 802.1X authentication, this standard assumes that IEEE 802.1X Supplicants and Authenticators exchange protocol information via the IEEE 802.1X Uncontrolled port. The IEEE 802.1X Controlled Port is blocked from passing general data traffic between the STAs until an IEEE 802.1X authentication procedure completes successfully over the IEEE 802.1X Uncontrolled Port. The security of an RSNA depends on this assumption being true.

In an infrastructure BSS or PBSS, if the STA associates with the AP or PCP, the STA indicates the IEEE 802.11 link is available by invoking the MLME-ASSOCIATE.confirm or MLME-REASSOCIATE.confirm primitive. This signals the Supplicant that the MAC has transitioned from the disabled to enabled state. At this point, the Supplicant's Controlled Port is blocked, and communication of all non-IEEE-802.1X MSDUs sent or received via the port is not authorized.

In an infrastructure BSS or PBSS, if the AP or PCP associates with a STA, the AP or PCP indicates that the IEEE 802.11 link is available by invoking the MLME-ASSOCIATE.indication or MLME-REASSOCIATE.indication primitive. At this point the Authenticator's Controlled Port corresponding to the STA's association is blocked, and communication of all non-IEEE-802.1X MSDUs sent or received via the Controlled Port is not authorized.

In an IBSS the STA shall block all IEEE 802.1X ports at initialization. Communication of all non-IEEE 802.1X MSDUs sent or received via the Controlled Port is not authorized.

In a PBSS, if a STA chooses not to associate with the PCP, the STA shall block all IEEE 802.1X ports at initialization. Communication of all non-IEEE-802.1X MSDUs sent or received via the Controlled Port is not authorized.

This standard assumes each Controlled Port remains blocked until the IEEE 802.1X state variables portValid and keyDone both become true. This assumption means that the IEEE 802.1X Controlled Port discards MSDUs sent across the IEEE 802.11 channel prior to the installation of cryptographic keys into the MAC. This protects the STA's host from forged MSDUs written to the channel while it is still being initialized.

The MAC does not distinguish between MSDUs for the Controlled Port, and MSDUs for the Uncontrolled Port. In other words, EAPOL-Start frames and EAPOL-Key frames are encrypted only after invocation of the MLME-SETPROTECTION.request primitive.

This standard assumes that IEEE Std 802.1X-2010 does not block the Controlled Port when authentication is triggered through reauthentication. During IEEE 802.1X reauthentication, an existing RSNA can protect all MSDUs exchanged between the STAs. Blocking MSDUs is not required during reauthentication over an RSNA.

12.6.10 RSNA authentication in an infrastructure BSS

12.6.10.1 General

When establishing an RSNA in a non-FT environment or during an FT initial mobility domain association, a STA shall use IEEE 802.11 SAE authentication or Open System authentication prior to (re)association.

SAE authentication is initiated when a STA's MLME-SCAN.confirm primitive finds another AP within the current ESS that advertises support for SAE in its RSNE.

IEEE 802.1X authentication is initiated by any one of the following mechanisms:

- If a STA negotiates to use IEEE 802.1X authentication during (re)association, the STA's management entity may respond to the MLME-ASSOCIATE.confirm (or indication) or MLME-REASSOCIATE.confirm (or indication) primitive by requesting the Supplicant (or Authenticator) to initiate IEEE 802.1X authentication. Thus, in this case, authentication is driven by the STA's decision to associate and the AP's decision to accept the association.
- If a STA's MLME-SCAN.confirm primitive finds another AP within the current ESS, a STA may signal its Supplicant to use IEEE Std 802.1X-2010 to preauthenticate with that AP.

NOTE—A roaming STA's IEEE 802.1X Supplicant can initiate preauthentication by sending an EAPOL-Start frame via its old AP, through the DS, to a new AP.

- If a STA receives an IEEE 802.1X message, it delivers this to its Supplicant or Authenticator, which may initiate a new IEEE 802.1X authentication.

12.6.10.2 Preauthentication and RSNA key management

Preauthentication allows a STA to perform RSNA authentication with an AP prior to attempting (re)association. This might reduce the time that the IEEE 802.1X port is not valid.

A STA shall not use preauthentication except when pairwise keys are employed. A STA shall not use preauthentication within the same mobility domain if AKM suite type 00-0F-AC:3 or 00-0F-AC:4 is used in the current association. Preauthentication shall not be used unless the new AP advertises the preauthentication capability in the RSNE.

When preauthentication is used, then:

- a) Authentication is independent of roaming.
- b) The Supplicant may authenticate with multiple APs at a time.

NOTE—Preauthentication might be useful as a performance enhancement, as reassociation does not include the protocol overhead of a full reauthentication when it is used.

Preauthentication uses the IEEE 802.1X protocol and state machines with EtherType 88-C7, rather than the EtherType 88-8E. Only IEEE 802.1X frame types EAP-Packet and EAPOL-Start are valid for preauthentication.

A Supplicant may initiate preauthentication when it has completed the 4-way handshake and configured the required temporal key(s). To effect preauthentication, the Supplicant sends an EAPOL-Start frame with the DA being the BSSID of a targeted AP and the RA being the BSSID of the AP with which it is associated. The target AP shall use a BSSID equal to the MAC address of its Authenticator. As preauthentication frames do not use the IEEE 802.1X EAPOL EtherType field, the AP with which the STA is currently associated need not apply any special handling. The AP and the MAC in the STA shall handle these frames in the same way as other frames with arbitrary EtherType field values that require distribution via the DS.

An AP's Authenticator that receives an EAPOL-Start frame via the DS may initiate IEEE 802.1X authentication to the STA via the DS. The DS forwards this message to the AP with which the STA is associated.

The result of preauthentication may be a PMKSA, if the IEEE 802.1X authentication completes successfully. The AKM shall be set to 00-0F-AC:1 in the PMKSA that results from preauthentication. If preauthentication produces a PMKSA, then, when the Supplicant's STA associates with the preauthenticated AP, the Supplicant may use the PMKSA with the 4-way handshake.

Successful completion of EAP authentication over IEEE Std 802.1X establishes a PMKSA at the Supplicant. The Authenticator has the PMKSA when the AS completes the authentication, passes the keying information (the master session key (MSK), a portion of which is the PMK) to the Authenticator, and the Authenticator creates a PMKSA using the PMK. The PMKSA is inserted into the PMKSA cache. Therefore, if the Supplicant and Authenticator lose synchronization with respect to the PMKSA, the 4-way handshake fails. In such circumstances, dot11RSNA4WayHandshakeFailures shall be incremented.

A Supplicant may initiate preauthentication with any AP within its present ESS with preauthentication enabled regardless of whether the targeted AP is within radio range.

Even if a STA has preauthenticated, it is still possible that it may have to undergo a full IEEE 802.1X authentication, as the AP's Authenticator may have purged its PMKSA due to, for example, unavailability of resources, delay in the STA associating, etc.

12.6.10.3 Cached PMKSAs and RSNA key management

In a non-FT environment, a STA might cache PMKSAs it establishes as a result of previous authentication. The PMKSA shall not be changed while cached. The PMKSA in the PMKSA is used with the 4-way handshake to establish fresh PTKs.

If a STA in an infrastructure BSS has determined it has a valid PMKSA with an AP to which it is about to (re)associate, it performs Open System authentication to the AP, and then it includes the PMKID for the PMKSA in the RSNE in the (Re)Association Request. When the PMKSA was not created using pre-authentication, the AKM indicated in the RSNE by the STA in the (Re)Association Request shall be identical to the AKM used to establish the cached PMKSA in the first place.

Upon receipt of a (Re)Association Request frame with one or more PMKIDs, an AP checks whether its Authenticator has cached a PMKSA for the PMKIDs and whether the AKM in the cached PMKSA matches the AKM in the (Re)Association Request; and if so, it shall assert possession of that PMKSA by beginning the 4-way handshake after association has completed. If the Authenticator does not have a PMKSA for the PMKIDs in the (Re)Association Request, its behavior depends on how the PMKSA was established. If SAE authentication was used to establish the PMKSA, then the AP shall reject (re)association by sending a (Re)Association Response frame with status code STATUS_INVALID_PMKID. Note that this allows the non-AP STA to fall back to full SAE authentication to establish another PMKSA. If IEEE 802.1X authentication was used to establish the PMKSA, the AP begins a full IEEE 802.1X authentication after association has completed.

If both sides assert possession of a cached PMKSA, but the 4-way handshake fails, both sides may delete the cached PMKSA for the selected PMKID.

If the lifetime of a cached PMKSA expires, the STA shall delete the expired PMKSA.

If a STA roams to an AP with which it is preauthenticating and the STA does not have a PMKSA for that AP, the STA needs to initiate a full IEEE 802.1X EAP authentication.

12.6.11 RSNA authentication in an IBSS

When authentication is used in an IBSS, it is driven by each STA wishing to establish communications. The management entity of this STA chooses a set of STAs with which it might need to authenticate and then may cause the MAC to send an IEEE 802.11 Open System authentication message to each targeted STA. Candidate STAs can be identified from Beacon frames, Probe Response frames, and Data frames from the same BSSID. Before communicating with STAs identified from Data frames, the security policy of the STAs may be obtained, e.g., by sending a Probe Request frame to the STA and obtaining a Probe Response frame. Targeted STAs that wish to respond may return an IEEE 802.11 Open System authentication message to the initiating STA.

When IEEE 802.1X authentication is used, the STA management entity requests its local IEEE 802.1X entity to create a Supplicant PAE for the peer STA. The Supplicant PAE initiates the authentication to the peer STA by sending an EAPOL-Start frame to the peer. The STA management entity also requests its local IEEE 802.1X entity to create an Authenticator PAE for the peer STA on receipt of the EAPOL-Start frame. The Authenticator initiates authentication to the peer STA by sending an EAP-Request message or, if PSK mode is in effect, message 1 of the 4-way handshake.

Upon initial authentication between any pair of STAs, Data frames, other than IEEE 802.1X messages, are not allowed to flow between the pair of STAs until both STAs in each pair of STAs have successfully completed AKM and have provided the supplied encryption keys.

Upon the initiation of an IEEE 802.1X reauthentication by any STA of a pair of STAs, Data frames continue to flow between the STAs while authentication completes. Upon a timeout or failure in the authentication process, the Authenticator of the STA initiating the reauthentication shall cause a Deauthentication message to be sent to the Supplicant of the STA targeted for reauthentication. The Deauthentication message causes both STAs in the pair of STAs to follow the deauthentication procedure defined in 11.3.4.4 and 11.3.4.5.

The IEEE 802.1X reauthentication timers in each STA are independent. If the reauthentication timer of the STA with the higher MAC address (see 12.7.1 for MAC comparison) triggers the reauthentication via its Authenticator, its Supplicant shall send an EAPOL-Start frame to the authenticator of the STA with the lower MAC address (see 12.7.1 for MAC comparison) to trigger reauthentication on the other STA. This process keeps the pair of STAs in a consistent state with respect to derivation of one or more fresh temporal keys upon an IEEE 802.1X reauthentication.

When it receives an MLME-AUTHENTICATE.indication primitive due to an Open System authentication request, the IEEE 802.11 management entity on a targeted STA shall, if it intends to set up a security association with the peer STA, request its Authenticator to begin IEEE 802.1X authentication, i.e., to send an EAP-Request/Identity message or message 1 of the 4-way handshake to the Supplicant.

The EAPOL-Key frame is used to exchange information between the Supplicant and the Authenticator to negotiate a fresh PTK. The 4-way handshake produces a single PTK from the PMK. The 4-way handshake and group key handshake use the PTK to protect the GTK as it is transferred to the receiving STA.

Password or PSK authentication may also be used in an IBSS. When a single password or PSK is shared among the IBSS STAs, an SAE capable STA wishing to establish communication with a STA that advertises support for SAE in Beacon and Probe Response frames invokes SAE authentication, and upon successful conclusion of SAE, sends 4-way handshake message 1 to the target STA. If the STA does not support SAE authentication or the target STA does not advertise support for SAE in Beacon and Probe Response frames, the STA may use the PSK as a PMK and initiate the 4-way handshake by sending a 4-way handshake message 1 to the target STA. In either case, the targeted STA responds to message 1 with message 2 of the 4-way handshake and begins its 4-way handshake by sending message 1 to the initiating STA. The two 4-way handshakes establish PTKSAs and GTKSAs to be used between the initiating STA and

the targeted STA. PSK PMKIDs have security vulnerabilities when used with low-entropy keys and should be used only after taking this into account.

The model for security in an IBSS is not general. In particular, it assumes the following:

- a) The sets of use cases for which the authentication procedures described in this subclause are valid are as follows:
 - 1) Password or PSK-based authentication using SAE to perform mutual authentication and generation of a shared PMK.
 - 2) An alternate form of PSK-based authentication, typically managed by the pass-phrase hash method as described in J.4. This method has security vulnerabilities and should only be used when SAE authentication is not possible.
 - 3) EAP-based authentication, using credentials that have been issued and preinstalled on the STAs within a common administrative domain, such as a single organization
- b) All of the STAs are in direct radio communication. In particular, there is no routing, bridging, or forwarding of traffic by a third STA to effect communication. This assumption is made, because the model makes no provision to protect IBSS topology information from tampering by one of the members.

12.6.12 RSNA authentication in an MBSS

When establishing an RSNA in an MBSS, a mesh STA shall use IEEE 802.11 SAE authentication (see 12.4), or optionally IEEE 802.1X authentication, prior to establishment of an authenticated peering. An RSNA security association, called a *mesh PMKSA*, is created upon successful completion of authentication. The mesh PMKSA is used with the AMPE to create a mesh TKSA.

A mesh PMKSA may be cached and used with the AMPE to establish a fresh mesh TKSA. A STA includes the PMKID for the PMKSA in the Mesh Peering Open frame. If the PMKID in a received Mesh Peering Open frame is unknown, the AMPE handshake fails. If both sides assert possession of a cached mesh PMKSA but the AMPE handshake fails, a STA may delete the cached mesh PMKSA for the selected PMKID. A mesh PMKSA shall not be changed while cached.

Authentication using IEEE 802.11 SAE authentication is based on a password. A password is required to be shared between two mesh STAs in order to successfully complete authentication. This password can be pairwise – each pair of mesh STAs in an MBSS has a unique password – or it can be shared-all mesh STAs in the MBSS share the same password.

Due to the security properties of IEEE 802.11 SAE authentication, an adversary has no greater possibility in determining a shared password than in determining a pairwise password. The potential for misuse, though, is greater if a shared password becomes known to an adversary because an unlimited number of mesh STAs under the control of the adversary can be added to the MBSS.

12.6.13 RSNA authentication in a PBSS

IEEE 802.11 Open System authentication is not used in a PBSS.

When establishing an RSNA with a PCP, a STA may associate to the PCP and initiate RSNA authentication with the PCP following the procedures of 12.6.10, with the PCP taking the role of the AP. When a STA chooses not to associate to a peer, it initiates RSNA authentication with the peer following the procedures of 12.6.11 with the following caveat: if both peers simultaneously initiate RSNA authentication, the peer with the lower MAC address shall abandon the authentication it initiated in favor of the authentication initiated by the peer with the higher MAC address.

12.6.14 RSNA key management in an infrastructure BSS

When the IEEE 802.1X authentication completes successfully, this standard assumes that the STA's IEEE 802.1X Suplicant and the IEEE 802.1X AS share a secret, called a *PMK*. In a non-FT environment, the AS transfers the PMK, within the MSK, to the AP, using a technique that is outside the scope of this standard; the derivation of the PMK from the MSK is EAP-method-specific. With the PMK in place, the AP initiates a key confirmation handshake with the STA. The key confirmation handshake sets the IEEE 802.1X state variable *portValid* (as described in IEEE Std 802.1X-2010) to true.

When SAE authentication completes, both STAs share a PMK. With this PMK in place, the AP initiates the key confirmation handshake with the STA.

The key confirmation handshake is implemented by the 4-way handshake. The purposes of the 4-way handshake are as follows:

- a) Confirm the existence of the PMK at the peer.
- b) Ensure that the security association keys are fresh.
- c) Synchronize the installation of one or more temporal keys into the MAC.
- d) Transfer the GTK from the Authenticator to the Suplicant.
- e) Confirm the selection of cipher suites.

NOTE 1—It is possible to forge message 1 of the 4-way handshake. However, the forgery attempt is detected in the failure of the 4-way handshake.

NOTE 2—Neither the AP nor the STA can use the PMK for any purpose but the one specified herein without compromising the key. If the AP uses it for another purpose, then the STA can masquerade as the AP; similarly if the STA reuses the PMK in another context, then the AP can masquerade as the STA.

The Suplicant and Authenticator signal the completion of key management by utilizing the MLME-SETKEYS.request primitive to configure the agreed-upon temporal pairwise key into the IEEE 802.11 MAC and by calling the MLME-SETPROTECTION.request primitive to enable its use.

A second key exchange, the group key handshake, is also defined. It distributes a subsequent GTK. The AP's Authenticator can use the group key handshake to update the GTK at the Suplicant. The group key handshake uses the EAPOL-Key frames for this exchange. When it completes, the Suplicant can use the MLME-SETKEYS.request primitive to configure the GTK into the IEEE 802.11 MAC.

12.6.15 RSNA key management in an IBSS

To establish a security association between two IBSS STAs, each STA's SME has an accompanying IEEE 802.1X Authenticator and Suplicant. Each SME initiates the 4-way handshake from the Authenticator to the peer STA's Suplicant (see 12.6.11). Two separate 4-way handshakes are conducted.

The 4-way handshake is used to negotiate the pairwise cipher suites, as described in 12.6.5. The IEEE 802.11 SME configures the temporal key portion of the PTK into the IEEE 802.11 MAC. Each Authenticator uses the KCK and KEK portions of the PTK negotiated by the exchange it initiates to distribute its own GTK and if management frame protection is enabled, its own IGTK. Each Authenticator generates its own GTK and if management frame protection is enabled, its own IGTK, and uses either the 4-way handshake or the group key handshake to transfer the GTK and if management frame protection is negotiated, the IGTK, to other STAs with whom it has completed a 4-way handshake. The pairwise key used between any two STAs shall be the pairwise key from the 4-way handshake initiated by the STA with the highest MAC address.

A STA joining an IBSS is required to adopt the security configuration of the IBSS, which includes the group cipher suite, pairwise cipher suite, AKMP, and if management frame protection is enabled, group

management cipher suite (see 12.6.5). The STA shall not set up a security association with any STA having a different security configuration. The Beacon and Probe Response frames of the various STAs within an IBSS need to reflect a consistent security policy, as the beacon initiation rotates among the STAs.

A STA joining an IBSS shall support and advertise in the Beacon frame the security configuration of the IBSS, which includes the group cipher suite, advertised pairwise cipher suite, AKMP, and if management frame protection is enabled, group management cipher suite (see 12.6.5). The STA may use the Probe Request frame to discover the security policy of a STA, including additional individual cipher suites the STA supports. If enabled, management frame protection shall only be used as a required feature (MFPR) in an IBSS.

NOTE—Because of the requirement for a STA joining an IBSS to support the security configuration of the IBSS, all Beacon frames transmitted in an IBSS have the same security policy.

12.6.16 RSNA key management in an MBSS

Upon successful completion of the AMPE, a secure mesh peering is established between two mesh STAs. This secure mesh peering includes a mesh PMKSA and a mesh TKSA. Multiple mesh TKSAs may be created using a single mesh PMKSA (a limit to that number is a policy decision outside the scope of this standard).

A mesh TKSA is logically a child of the mesh PMKSA. A mesh TKSA shall be deleted if the corresponding mesh PMKSA, which was used by the AMPE to create it, is deleted. Mesh PMKSAs are limited by their lifetime (see 12.7.1.3).

12.6.17 RSNA key management in a PBSS

Upon successful association and authentication in a PBSS, a STA performs a key confirmation handshake with the PCP, following the procedures in 12.6.14 with the PCP taking the role of the AP. If a STA chooses not to associate to a peer, after successful authentication, it performs a key confirmation handshake with the peer following the procedures in 12.6.15 with the following caveat: if both peers simultaneously initiate the key confirmation handshake, the peer with the lower MAC address shall abandon the handshake it initiated in favor of the handshake initiated by the peer with the higher MAC address.

12.6.18 RSNA security association termination

When a non-AP STA's SME receives a successful MLME-ASSOCIATE.confirm or MLME-REASSOCIATE.confirm primitive that is not part of a fast BSS transition or receives or invokes an MLME Disassociation or Deauthentication primitive, it deletes some security associations. Similarly, when an AP's SME

- receives an MLME-ASSOCIATE.indication or MLME-REASSOCIATE.indication primitive from a STA that has not negotiated management frame protection, or
- receives an MLME-ASSOCIATE.indication or MLME-REASSOCIATE.indication primitive from a STA that has negotiated management frame protection that a) has resulted in an MLME (re)association response that is successful, and b) is not part of a fast BSS transition, or receives an MLME-DEAUTHENTICATE.indication or MLME-DISASSOCIATE.indication primitive or issues an MLME-DEAUTHENTICATE.request or MLME-DISASSOCIATE.request primitive,

it deletes some security associations. In the case of an ESS, the non-AP STA's SME shall delete the PTKSA, GTKSA, IGTKSA, SMKSA, any TPKSA, and any STKSA, and the AP's SME shall delete the PTKSA and invoke an STSL application teardown procedure for any of its STKSAs. An example of an STSL application teardown procedure is described in 11.7.4. In the case of an IBSS, the SME shall delete the PTKSA and the receive GTKSA and IGTKSA. Once the security associations have been deleted, the SME then invokes

MLME-DELETEKEYS.request primitive to delete all temporal keys associated with the deleted security associations.

If a STA loses key state synchronization, it can apply the following rules to recover:

- a) Any protected frame(s) received shall be discarded, and MLME-PROTECTEDFRAMEDROPPED.indication primitive is invoked.
- b) If the STA is RSNA-enabled and has joined an IBSS, the SME shall execute the authentication procedure as described in 11.3.4.2.
- c) If the STA is RSNA-enabled and has joined an ESS, the SME shall execute the deauthentication procedures as described in 11.3.4.4. However, if the STA has initiated the RSN security association, but has not yet invoked the MLME-SETPROTECTION.request primitive, then no additional action is required.

NOTE 1—There is a race condition between when MLME-SETPROTECTION.request primitive is invoked on the Suplicant and when it is invoked on the Authenticator. During this time, the STA might receive an MPDU that it is unable to decrypt; and the MPDU is discarded without a deauthentication occurring.

NOTE 2—Because the IEEE 802.11 Null frame does not derive from an MA-UNITDATA.request primitive, it is not protected.

If the selected AKMP fails between a STA and an AP that are associated, then both the STA and the AP shall invoke the MAC deauthentication procedure described in 11.3.4.4.

If the SMK handshake fails between a pair of associated STAs and AP, then the STAs and the AP shall invoke an STSL application teardown procedure.

When a STA's SME receives an MLME-PN-EXHAUSTION.indication primitive and the PN is associated with a PTKSA, the STA's SME shall invoke an MLME-DISASSOCIATE.request primitive and delete the PTKSA.

When a STA's SME receives an MLME-PN-EXHAUSTION.indication primitive and the PN is associated with a GTKSA, the STA's SME shall delete the GTKSA.

When a STA's SME receives an MLME-PN-EXHAUSTION.indication primitive and the PN is associated with a STKSA, the STA's SME shall invoke a STSL application teardown procedure for the STKSA and delete the STKSA.

Once the security associations have been deleted, the SME then invokes MLME-DELETEKEYS.request primitive to delete all temporal keys associated with the deleted security associations.

12.6.19 Protection of robust Management frames

This subclause defines rules that shall be followed by STAs that implement Management Frame protection and have dot11RSNAActivated equal to true.

A STA with dot11RSNAProtectedManagementFramesActivated equal to false shall transmit and receive unprotected individually addressed robust Management frames to and from any associated STA and shall discard protected individually addressed robust Management frames received from any associated STA.

A STA with dot11RSNAProtectedManagementFramesActivated equal to true and dot11RSNAUnprotectedManagementFramesAllowed equal to true shall transmit and receive unprotected individually addressed robust Management frames to and from any associated STA that advertised MFPC = 0 and shall discard protected individually addressed robust Management frames received from any associated STA that advertised MFPC = 0.

A STA with dot11RSNAProtectedManagementFramesActivated equal to true and dot11RSNAUnprotectedManagementFramesAllowed equal to true shall transmit and receive protected individually addressed robust Management frames to and from any associated STA that advertised MFPC = 1, shall discard unprotected individually addressed robust Action frames received from any STA that advertised MFPC = 1, and shall discard unprotected individually addressed Disassociation and Deauthentication frames received from a STA that advertised MFPC = 1 after the PTK and IGTK have been installed. The receiver shall process unprotected individually addressed Disassociation and Deauthentication frames before the PTK and IGTK are installed.

A STA with dot11RSNAProtectedManagementFramesActivated equal to true and dot11RSNAUnprotectedManagementFramesAllowed equal to false shall transmit and receive protected individually addressed robust Action frames to and from any STA, shall not transmit unprotected individually addressed robust Action frames to any STA, and shall discard unprotected individually addressed robust Action frames received from a STA after the PTK and IGTK have been installed. The receiver shall process unprotected individually addressed Disassociation and Deauthentication frames before the PTK and IGTK are installed.

A STA with dot11RSNAProtectedManagementFramesActivated equal to true shall protect transmitted group addressed robust Management frames using the group management cipher suite.

A STA with dot11RSNAProtectedManagementFramesActivated equal to true shall discard group addressed robust Management frames received from any associated STA that advertised MFPC = 1 if the frames are unprotected or if a matching IGTK is not available.

A STA with dot11RSNAProtectedManagementFramesActivated equal to true and dot11RSNAUnprotectedManagementFramesAllowed equal to false shall discard received group addressed robust Management frames that are unprotected or for which a matching IGTK is not available.

A STA with dot11RSNAProtectedManagementFramesActivated equal to false shall transmit group addressed robust Management frames unprotected and shall ignore the protection on received group addressed robust Management frames.

NOTE—BIP does not provide protection against forgery by associated and authenticated STAs. A STA that has left the group can successfully forge Management frames until the IGTK is updated.

Protection of group addressed robust Management frames shall be provided by a service in the MLME as described in 11.13.

Robust management frame protection cannot be applied until the PTK and IGTK has been established with the STA. A STA shall not transmit robust Action frames until it has installed the PTK for the peer STA, or in the case of group addressed frames, has installed the IGTK. The STA shall discard any robust Action frames received before the PTK and IGTK are installed.

12.6.20 Robust management frame selection procedure

A STA with dot11RSNAProtectedManagementFramesActivated equal to true shall negotiate robust management frame protection with a STA that advertised MFPC = 1.

When a Public Action frame is transmitted for which a Protected Dual of Public Action frame is defined, (see 9.6.11), which variant (i.e., protected or not protected) is used depends on the setting of the “Protected” parameter of the corresponding MLME .request or .confirm primitive. Where there is no such parameter, the protected variant is used when management frame protection has been negotiated.

12.6.21 RSNA rekeying

When a PTKSA is deleted, a non-AP and non-PCP STA may reassociate with the same AP or PCP and/or establish a new RSNA with the AP or PCP. If the non-AP and non-PCP STA has cached one or more PMKSAs, it may skip the PMKSA establishment and proceed with the creation of a new PTKSA by using 4-way handshake.

When a GTKSA is deleted, an originating STA may create a new GTKSA by using 4-way handshake or group key handshake.

When a STKSA is deleted, the STA_I may establish a new STSL with the STA_P. If the SMK between the STA pair has not expired, the STA_I may initiate a 4-way handshake and create a new STKSA with STA_P. If the SMK has expired, the STA_I shall create both a new SMKSA and a new STKSA with the STA_P.

An Authenticator/STA_I may initiate a 4-way handshake for the purpose of renewing the key associated with a PTKSA or STKSA. A supplicant/STA_P may send an EAPOL request message to the authenticator/STA_I to request rekeying. In addition, if both the Authenticator and the Supplicant support multiple keys for individually addressed traffic, a smooth switchover to the new key is possible using the following procedure.

The IEEE 802.11 MAC shall issue an MLME-PN-WARNING.indication primitive when the Packet Number assignment for a particular PTKSA, GTKSA, or STKSA reaches or exceeds the threshold that is defined in dot11PNWarningThresholdLow and dot11PNWarningThresholdHigh for the first time. The indication shall be issued only once for a given PTKSA, GTKSA, or STKSA. The SME may use the indication as a trigger to establish a new PTKSA, GTKSA, or STKSA before the Packet Number space is exhausted.

A PTKSA or STKSA has a limited lifetime, either in absolute time or due to exhausting the PN space. To maintain an uninterrupted security association, a STA should establish a new PTKSA or STKSA prior to the expiration of the old PTKSA or STKSA.

When both ends of the link support extended Key IDs for individually addressed frames, it is possible to install the new PTKSA or STKSA without data loss, provided the new PTKSA or STKSA uses a different Key ID from the old PTKSA or STKSA. Data loss might occur if the same Key ID is used because it is not possible to precisely coordinate (due to software processing delays) when the new key is used for transmit at one end and when it is applied to receive at the other end. If a different Key ID is used for the new PTKSA or STKSA, then provided the new key is installed at the receive side prior to its first use at the transmit side there is no need for precise coordination. During the transition, received packets are unambiguously identified using the Key ID as belonging to either the old or new PTKSA or STKSA.

12.6.22 Multi-band RSNA

12.6.22.1 General

A STA is multi-band capable and RSNA-capable if the values of both dot11MultibandImplemented and dot11RSNAActivated are true.

A STA that is multi-band capable and RSNA-capable shall set the Pairwise Cipher Suite Present field of the Multi-band element to 1 and shall include the Pairwise Cipher Suite Count field and the Pairwise Cipher Suite List field in the Multi-band element. The STA may include the RSNE and the Multi-band element in the DMG Beacon and Announce frames and shall include the RSNE and the Multi-band element in Beacon, Probe Response, and Information Response frames. The included RSNE shall specify all of the authentication and cipher suites enabled by the STA's policy for the band where this element is transmitted, and the included Multi-band element shall specify all of the pairwise cipher suites enabled by the STA's

policy for the band specified within the Multi-band element. A STA shall not advertise any cipher suite that is not enabled.

A multi-band capable and RSNA-capable STA shall include the Multi-band element in the (Re)Association Request frame and in message 2 and message 3 of the 4-way handshake.

In order to set up an RSNA with a peer STA for a supported band/channel, a STA that does not know the peer's policy for the band/channel shall first obtain the peer STA's policy for the supported band/channel by using a Probe Request frame or Information Request frame. The STA initiating RSNA establishment for a supported band/channel is called *RSNA initiator*, and the targeted STA of the RSNA establishment is called *RSNA responder*.

A multi-band capable device can create its own group key(s) for one or more supported bands/channels. If the STA uses different MAC addresses in different bands/channels, different GTKSAs shall be created for different bands. If the STA uses a same MAC address in all supported bands/channels, a single GTKSA shall be created for all supported bands/channels.

If the pairwise and group cipher suites used by a pair of multi-band capable devices to communicate with each other in the current operating band/channel is also supported after the transfer to another band/channel that was performed using transparent FST, the devices shall continue using the same cipher suites to communicate with each other after the transfer. In all other cases, a separate RSNA has to be established for the other band/channel (see 12.6.22).

12.6.22.2 Nontransparent multi-band RSNA

An RSNA initiator can establish a nontransparent (11.33) multi-band RSNA with an RSNA responder for a supported band/channel other than the current operating band/channel. The two STAs use the same PMKSA for both the supported band/channel and the current operating band/channel and create different PTKSAs for different bands/channels.

If the RSNA initiator does not have an existing PMKSA with the RSNA responder, the RSNA initiator shall first establish a PMKSA with the RSNA responder in the current operating band/channel and then use the PMKSA to create a PTKSA with the RSNA responder for the supported band/channel. If the RSNA initiator has already established a PMKSA with the RSNA responder, the PMKSA shall be used to create a PTKSA between the two STAs for the supported band/channel.

With the PMK in place, the RSNA initiator and RSNA responder can proceed in two ways depending on the setting of the Joint Multi-band RSNA subfield within the RSN Capabilities field in the RSNE of both STAs.

If the Joint Multi-band RSNA subfield within the RSN Capabilities field of either the RSNA initiator or RSNA responder is 0, the STA pair uses a 4-way handshake to establish a PTKSA for the current band/channel and may start a separate 4-way handshake in the current operating band/channel to negotiate a pairwise cipher suite for the supported band/channel and establish a PTKSA for the supported band/channel. As specified in 12.7.6, message 2 and message 3 of the 4-way handshake convey the Multi-band element associated with the supported band/channel. The Multi-band element in message 2 includes the selected pairwise cipher suite for the supported band/channel. message 3 includes the Multi-band element that the STA would send in a Beacon, DMG Beacon, Announce, Probe Response, or Information Response frame. message 3 may include a second Multi-band element that indicates the STA's pairwise cipher suite assignment for the supported band/channel.

If the Joint Multi-band RSNA subfield within the RSN Capabilities field is 1 for both the RSNA initiator and the RSNA responder and at least one of the STAs uses different MAC addresses for different bands/channels, the STAs shall use a single 4-way handshake to negotiate pairwise cipher suites and establish PTKSAs for both the current operating band/channel and the other supported band(s)/channel(s). As

specified in 12.7.6, message 2 and message 3 of the 4-way handshake convey the RSNE and the Multi-band element(s). The RSNE in message 2 includes the selected pairwise cipher suite for the current operating band/channel, and the Multi-band element(s) in message 2 includes the selected pairwise cipher suite(s) for the other supported band(s)/channel(s). message 3 includes the RSNE and the Multi-band element(s) that the STA would send in a Beacon, DMG Beacon, Announce, Probe Response, or Information Response frame. message 3 may include a second RSNE and Multi-band element(s) that indicate the STA's pairwise cipher suite assignments for the current operating band/channel and the other supported band(s)/channel(s). KCK and KEK associated with the current operating band/channel shall be used in the 4-way handshake.

12.6.22.3 Transparent multi-band RSNA

An RSNA initiator can establish a transparent (11.33) multi-band RSNA with an RSNA responder for both the current operating band/channel and the other supported band(s)/channel(s) if

- a) Both STAs use the same MAC address in the current operating band/channel and the other supported band(s)/channel(s); and
- b) At least one common pairwise cipher suite is supported by both STAs in the current operating band/channel and the other supported band(s)/channel(s).

Two STAs that establish a transparent multi-band RSNA create one PMKSA and one PTKSA for both the current operating band/channel and other supported band(s)/channel.

A STA shall use a single PN counter (12.5.3.3 and 12.5.5.3) for transmission in both the current operating band and the other supported band(s) when transparent multi-band RSNA is used.

If the RSNA initiator does not have an existing PMKSA with the RSNA responder, the RSNA initiator shall first establish a PMKSA with the RSNA responder in the current operating band/channel and then use the PMKSA to create a PTKSA with the RSNA responder for all involved bands/channels. If the RSNA initiator has already established a PMKSA with the RSNA responder, the PMKSA shall be used to create a PTKSA between the two STAs for all involved bands/channels.

With the PMK in place, the STA pair shall use a single 4-way handshake in the current operating band/channel to negotiate a pairwise cipher suite for all involved bands/channels and also establish a single PTKSA for all involved bands/channels. As specified in 12.7.6, message 2 and message 3 of the 4-way handshake convey the RSNE and the Multi-band element(s). The RSNE and the Multi-band element(s) in message 2 include one selected pairwise cipher suite for all involved bands/channels. message 3 includes the RSNE and the Multi-band element(s) that the STA would send in a Beacon, DMG Beacon, Announce, Probe Response, or Information Response frame. message 3 may include a second RSNE and Multi-band element(s) that indicate the STA's pairwise cipher suite assignment for all involved bands/channels.

12.6.22.4 Multi-band RSNA with TDLS in a non-DMG BSS

When two multi-band capable devices operate in a non-DMG BSS and set up a TDLS direct link in the BSS, the TPK handshake protocol can be used to create a PTKSA for use in another supported band/channel that is supported by both STAs and that was indicated in the Multi-band element in each of the STAs. Only TK in PTKSA is required for the supported band/channel and it shall be equal to the TPK-TK of the TPK.

If at least one of the peer STAs has a different MAC address in the supported band/channel from that of the current operating band/channel, the TPK handshake protocol may be used to establish a PTKSA for the supported band/channel. In this case, the TPK creation method shall be used to calculate a different PTKSA in the supported band/channel: the TDLS peer MAC addresses and cipher suite shall be replaced by the MAC addresses and cipher suite indicated within the corresponding Multi-band elements contained in the TDLS Setup Request and TDLS Setup Response frames used to establish the PTKSA for the supported band/channel.

If two TDLS peer STAs use the same MAC addresses and pairwise cipher suites in the operating band/channel and in the supported band/channel, the TPKSA that is acquired by the successful completion of the TPK handshake protocol may be used as the PTKSA for the supported band/channel.

12.7 Keys and key distribution

12.7.1 Key hierarchy

12.7.1.1 General

RSNA defines the following key hierarchies:

- a) Pairwise key hierarchy, to protect individually addressed traffic
- b) GTK, a hierarchy consisting of a single key to protect group addressed traffic

NOTE—Pairwise key support with enhanced data cryptographic encapsulation mechanisms allows a receiving STA to detect MAC address spoofing and data forgery. The RSNA architecture binds the transmit and receive addresses to the pairwise key. If an attacker creates an MPDU with the spoofed TA, then the decapsulation procedure at the receiver generates an error. GTKs do not have this property.

- c) Integrity GTK (IGTK), a hierarchy consisting of a single key to provide integrity protection for group addressed robust Management frames

The description of the key hierarchies uses the pseudorandom function producing n bits of output, PRF- n , defined in 12.7.1.2.

In an infrastructure BSS, the IEEE 802.1X Authenticator MAC address (AA) and the AP's MAC address are the same, and the Supplicant's MAC address (SPA) and the STA's MAC address are equal. For the purposes of comparison, the MAC address is encoded as 6 octets, taken to represent an unsigned integer. The first octet of the MAC address shall be used as the most significant octet. The bit numbering conventions in 9.2.2 shall be used within each octet. This results in a 48-bit unsigned integer labeled B0 (least significant) to B47 (most significant), where the I/G bit is in B40.

An RSNA STA shall support at least one pairwise key for any <TA,RA> pair for use with enhanced data cryptographic encapsulation mechanisms. The <TA,RA> identifies the pairwise key, which does not correspond to any WEP key identifier.

In a mixed environment, an AP may simultaneously communicate with some STAs using WEP with shared WEP keys and to STAs using enhanced data cryptographic encapsulation mechanisms with pairwise keys. The STAs running WEP use default keys 0–3 for shared WEP keys; the important point here is that WEP can still use WEP default key 0. The AP might be configured to use the WEP key in WEP default key 0 for WEP; if the AP is configured in this way, STAs that cannot support WEP default key 0 simultaneously with a TKIP pairwise key shall specify the No Pairwise subfield in the RSN Capabilities field. If an AP is configured to use WEP default key 0 as a WEP key and a “No Pairwise” STA associates, the AP shall not set the Install bit in the 4-way handshake. In other words, the STA does not install a pairwise temporal key and instead uses WEP default key 0 for all traffic.

NOTE—The behavior of “No Pairwise” STAs is intended only to support the migration of WEP to RSNA.

TKIP STAs in a mixed environment are expected to support a single pairwise key either by using a key mapping key or by mapping to default key 0. The AP uses a pairwise key for individually addressed traffic between the AP and the STA. If a key mapping key is available, the <RA,TA> pair identifies the key; if there is no key mapping key, then the default key 0 is used because the key index in the message is 0.

A STA that cannot support TKIP keys and WEP default key 0 simultaneously advertises this deficiency by setting the No Pairwise subfield in the RSNE it sends in the (Re)Association Request frame to the AP. In response, the AP sets the Install bit to 0 in message 3 of the 4-way handshake to notify the STA not to install the pairwise key. The AP instead sends the WEP shared key to the STA to be plumbed as the WEP default key 0; this key is then used with WEP to send and receive individually addressed traffic between the AP and the STA.

The TKIP STA that has this limitation might not know that it will be forced to use WEP for all transmissions until it has associated with the AP and been given the keys to use. (The STA cannot know that the AP has been configured to use WEP default key 0 for WEP communication.) If this does not satisfy the security policy configured at the STA, the STA's only recourse is to disassociate and try a different AP.

STAs using enhanced data cryptographic encapsulation mechanisms in a TSN shall support pairwise keys and WEP default key 0 simultaneously. It is invalid for the STA to negotiate the No Pairwise subfield when an enhanced data cryptographic encapsulation mechanism other than TKIP is one of the configured ciphers.

12.7.1.2 PRF

A PRF is used in a number of places in this standard. Depending on its use, it may need to output 128, 192, 256, 384, 512, or 704 bits. This subclause defines six functions:

- PRF-128, which outputs 128 bits
- PRF-192, which outputs 192 bits
- PRF-256, which outputs 256 bits
- PRF-384, which outputs 384 bits
- PRF-512, which outputs 512 bits
- PRF-704, which outputs 704 bits

In the following, K is a key; A is a unique label for each different purpose of the PRF, treated as an ASCII string; B is a variable-length string; Y is a single octet containing 0; X is a single octet containing the loop parameter i :

$H\text{-SHA-1}(K, A, B, X) \leftarrow HMAC\text{-SHA-1}(K, A \parallel Y \parallel B \parallel X)$

```

PRF( $K, A, B, Len$ )
    for  $i \leftarrow 0$  to  $\lceil \frac{Len}{160} \rceil$  do
         $R \leftarrow R \parallel H\text{-SHA-1}(K, A, B, i)$ 
    return  $L(R, 0, Len)$ 

```

$PRF\text{-}128(K, A, B) = PRF(K, A, B, 128)$
 $PRF\text{-}192(K, A, B) = PRF(K, A, B, 192)$
 $PRF\text{-}256(K, A, B) = PRF(K, A, B, 256)$
 $PRF\text{-}384(K, A, B) = PRF(K, A, B, 384)$
 $PRF\text{-}512(K, A, B) = PRF(K, A, B, 512)$

When the negotiated AKM is 00-0F-AC:5, 00-0F-AC:6, or 00-0F-AC:11, the KDF specified in 12.7.1.7.2 shall be used instead of the PRF construction defined here. In this case, A is used as the KDF label and B as the KDF Context, and the PRF functions are defined as follows:

$PRF\text{-}128(K, A, B) = KDF\text{-}SHA\text{-}256\text{-}128(K, A, B)$
 $PRF\text{-}192(K, A, B) = KDF\text{-}SHA\text{-}256\text{-}192(K, A, B)$

$$\text{PRF-256}(K, A, B) = \text{KDF-SHA-256-256}(K, A, B)$$

$$\text{PRF-384}(K, A, B) = \text{KDF-SHA-256-384}(K, A, B)$$

$$\text{PRF-512}(K, A, B) = \text{KDF-SHA-256-512}(K, A, B)$$

When the negotiated AKM is 00-0F-AC:12, the KDF specified in 12.7.1.7.2 shall be used instead of the PRF construction defined here. In this case, A is used as the KDF label and B as the KDF Context, and the PRF function is defined as follows:

$$\text{PRF-704}(K, A, B) = \text{KDF-SHA-384-704}(K, A, B)$$

When the negotiated AKM is 00-0F-AC:13, the KDF specified in 12.7.1.7.2 shall be used instead of the PRF construction defined here. In this case, A is used as the KDF label and B as the KDF Context, and the PRF functions are defined as follows:

$$\text{PRF-384}(K, A, B) = \text{KDF-SHA-384-384}(K, A, B)$$

$$\text{PRF-512}(K, A, B) = \text{KDF-SHA-384-512}(K, A, B)$$

$$\text{PRF-704}(K, A, B) = \text{KDF-SHA-384-704}(K, A, B)$$

12.7.1.3 Pairwise key hierarchy

Except when preauthentication is used, the pairwise key hierarchy utilizes PRF-384, PRF-512, or PRF-704 to derive session-specific keys from a PMK, as depicted in Figure 12-28. When using AKM suite selector 00-0F-AC:12, the length of the PMK, PMK_bits, shall be 384 bits. With all other AKM suite selectors, the length of the PMK, PMK_bits, shall be 256 bits. The pairwise key hierarchy takes a PMK and generates a PTK. The PTK is partitioned into KCK, KEK, and a temporal key, which is used by the MAC to protect individually addressed communication between the Authenticator's and Supplicant's respective STAs. PTKs are used between a single Supplicant and a single Authenticator.

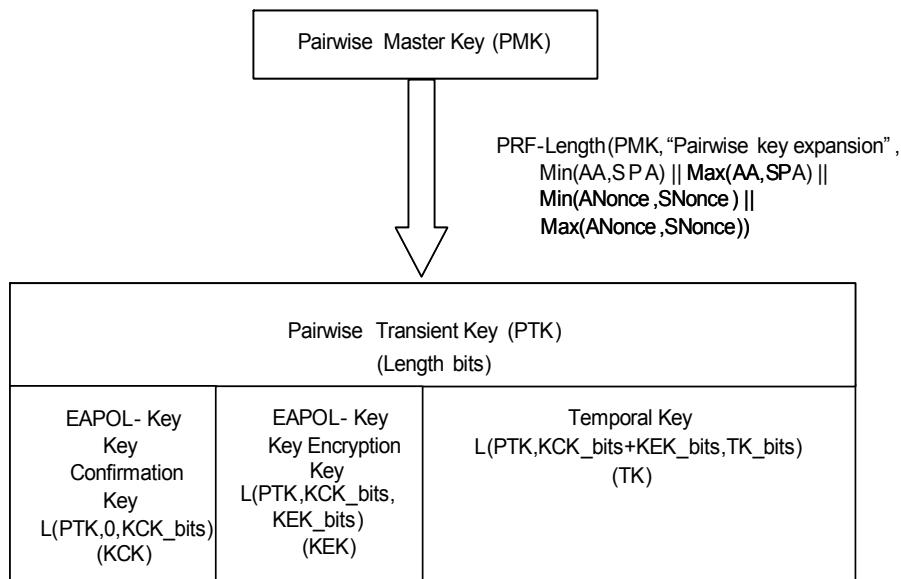

Figure 12-28—Pairwise key hierarchy

When not using a PSK, the PMK is derived from the MSK. The PMK shall be computed as the first PMK_bits bits (bits 0 to PMK_bits-1) of the MSK: $\text{PMK} = L(\text{MSK}, 0, \text{PMK_bits})$.

The PTK shall not be used longer than the PMK lifetime as determined by the minimum of the PMK lifetime indicated by the AS, e.g., Session-Timeout + dot1xAuthTxPeriod or from dot11RSNAConfigPMK-Lifetime. When RADIUS is used and the Session-Timeout attribute is not in the RADIUS Accept message, and if the key lifetime is not otherwise specified, then the PMK lifetime is infinite.

NOTE 1—If the protocol between the Authenticator (or AP) and AS is RADIUS, then the MS-MPPE-Recv-Key attribute (vendor-id = 17; see Section 2.4.3 in IETF RFC 2548 [B32]) is available to be used to transport the first 32 octets of the MSK to the AP, and the MS-MPPE-Send-Key attribute (vendor-id = 16; see Section 2.4.2 in IETF RFC 2548 [B32]) is available to be used to transport the remaining 32 octets of the MSK.

NOTE 2—When reauthenticating and changing the pairwise key, a race condition might occur when using TKIP. If a frame is received while MLME-SETKEYS.request primitive is being processed, the received frame might be decrypted with one key and the MIC checked with a different key. Two possible options to avoid this race condition are as follows: the frame might be checked against the old MIC key, and the received frames might be queued while the keys are changed.

NOTE 3—if the AKMP is RSNA-PSK, then a 256-bit PSK might be configured into the STA and AP or a pass-phrase might be configured into the Supplicant or Authenticator. The method used to configure the PSK is outside this standard, but one method is via user interaction. If a pass-phrase is configured, then a 256-bit key is derived and used as the PSK. In any RSNA-PSK method, the PSK is used directly as the PMK. Implementations might support different PSKs for each pair of communicating STAs.

Here, the following assumptions apply:

- SNonce is a random or pseudorandom value contributed by the Supplicant; its value is taken when a PTK is instantiated and is sent to the PTK Authenticator.
- ANonce is a random or pseudorandom value contributed by the Authenticator.
- The PTK shall be derived from the PMK by

$$\text{PTK} = \text{PRF-Length(PMK, "Pairwise key expansion", Min(AA,SPA) \parallel Max(AA,SPA) \parallel Min(ANonce,SNonce) \parallel Max(ANonce,SNonce))}$$

where Length = KCK_bits + KEK_bits + TK_bits. The values of KCK_bits and KEK_bits are AKM suite dependent and are listed in Table 12-8. The value of TK_bits is cipher-suite dependent and is defined in Table 12-4. The Min and Max operations for IEEE 802 addresses are with the address converted to a positive integer treating the first transmitted octet as the most significant octet of the integer. The nonces are encoded as specified in 9.2.2.

NOTE—The Authenticator and Supplicant normally derive a PTK only once per association. A Supplicant or an Authenticator use the 4-way handshake to derive a new PTK. Both the Authenticator and Supplicant create a new nonce value for each 4-way handshake instance.

- The KCK shall be computed as the first KCK_bits bits (bits 0 to KCK_bits-1) of the PTK:

$$\text{KCK} = L(\text{PTK}, 0, \text{KCK_bits})$$

The KCK is used by IEEE Std 802.1X-2010 to provide data origin authenticity in the 4-way handshake and group key handshake messages.
- The KEK shall be computed as the next KEK_bits bits of the PTK:

$$\text{KEK} = L(\text{PTK}, \text{KCK_bits}, \text{KEK_bits})$$

The KEK is used by the EAPOL-Key frames to provide data confidentiality in the 4-way handshake and group key handshake messages.
- The temporal key (TK) shall be computed as the next TK_bits bits of the PTK:

$$\text{TK} = L(\text{PTK}, \text{KCK_bits+KEK_bits}, \text{TK_bits})$$

The EAPOL-Key state machines (see 12.7.10 and 12.7.11) use the MLME-SETKEYS.request primitive to configure the temporal key into the STA. The STA uses the temporal key with the pairwise cipher suite; interpretation of this value is cipher-suite-specific.

When the negotiated AKM is 00-0F-AC:5 or 00-0F-AC:6, the PMK identifier is defined as

$$\text{PMKID} = \text{Truncate-128}(\text{HMAC-SHA-256}(\text{PMK}, \text{"PMK Name"} \parallel \text{AA} \parallel \text{SPA}))$$

When the negotiated AKM is 00-0F-AC:11, the PMK identifier is defined as

$$\text{PMKID} = \text{Truncate-128}(\text{HMAC-SHA-256}(\text{KCK}, \text{"PMK Name"} \parallel \text{AA} \parallel \text{SPA}))$$

When the negotiated AKM is 00-0F-AC:12, and the PMK identifier is defined as

$$\text{PMKID} = \text{Truncate-128}(\text{HMAC-SHA-384}(\text{KCK}, \text{"PMK Name"} \parallel \text{AA} \parallel \text{SPA}))$$

Otherwise, the PMK identifier is defined as

$$\text{PMKID} = \text{Truncate-128}(\text{HMAC-SHA-1}(\text{PMK}, \text{"PMK Name"} \parallel \text{AA} \parallel \text{SPA}))$$

In all these cases, “PMK Name” is treated as an ASCII string.

When the PMKID is calculated for the PMKSA as part of preauthentication, the AKM has not yet been negotiated. In this case, the HMAC-SHA-1 based derivation is used for the PMKID calculation.

12.7.1.4 Group key hierarchy

The group temporal key (GTK) shall be a random number. The following is an example method for deriving a random GTK. Any other pseudorandom function, such as that specified in 12.7.1.2, could also be used.

A group master key (GMK) is an auxiliary key that may be used to derive a GTK at a time interval configured into the AP to reduce the exposure of data if the GMK is ever compromised.

The Authenticator might update the GTK for a number of reasons:

- The Authenticator might change the GTK on disassociation or deauthentication of a STA.
- An event within the SME might trigger a group key handshake.

Figure 12-29 depicts an example of a relationship among the keys of the group key hierarchy. In this model, the group key hierarchy takes a GMK and generates a GTK. The GTK is a temporal key, which is used to protect group addressed communication. GTKs are used between a single Authenticator and all Supplicants authenticated to that Authenticator. The Authenticator derives new GTKs when it needs to update the GTKs.

In this example, the following assumptions apply:

- a) Group nonce (GNonce) is a random or pseudorandom value contributed by the IEEE 802.1X Authenticator.
- b) The GTK is derived from the GMK by
- c) $\text{GTK} = \text{PRF-Length}(\text{GMK}, \text{"Group key expansion"}, \text{AA} \parallel \text{GNonce})$
- d) Length = TK_bits. The value of TK_bits is cipher-suite dependent and is defined in Table 12-4. AA is represented as an IEEE 802 address and GNonce as a bit string as defined in 9.2.2.
- e) The temporal key (TK) is bits 0 to (TK_bits – 1) of the GTK:
 $\text{TK} = \text{L(GTK, 0, TK_bits)}$
- f) The EAPOL-Key state machines (see 12.7.10 and 12.7.11) configure the temporal key into a STA via the MLME-SETKEYS.request primitive. Its interpretation is cipher-suite-specific.

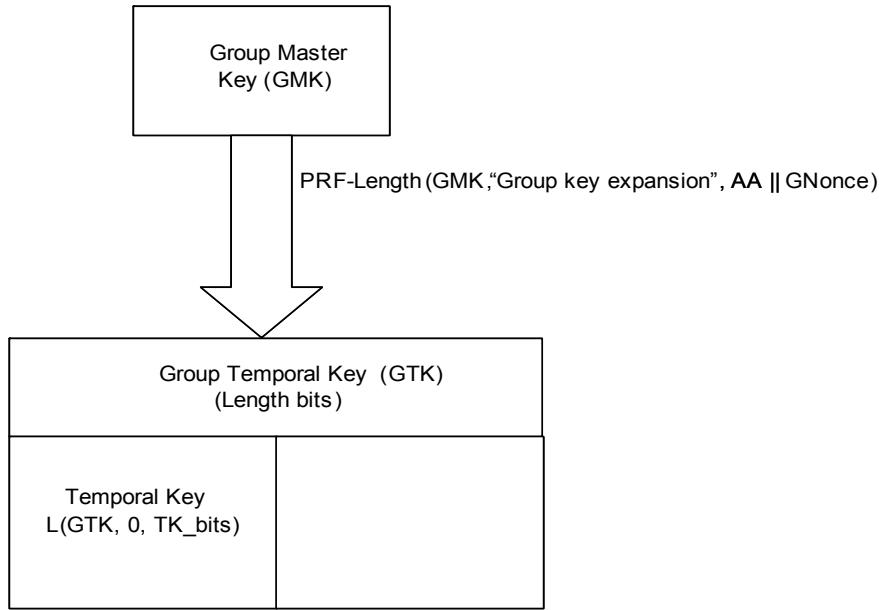

Figure 12-29—Group key hierarchy (informative)

12.7.1.5 Integrity group key hierarchy

The Authenticator shall select the IGTK as a random value each time it is generated.

The Authenticator may update the IGTK for any reason, including:

- a) The disassociation or deauthentication of a STA.
- b) An event within the SME that triggers a group key handshake.

The IGTK is configured via the MLME-SETKEYS.request primitive; see 6.3.19. IGTK configuration is described in the EAPOL-Key state machines; see 12.7.10 and 12.7.11.

The IPN is used to provide replay protection.

12.7.1.6 PeerKey key hierarchy

The station-to-station key hierarchy utilizes PRF-384 or PRF-512 to derive session-specific keys from an SMK, as depicted in Figure 12-30. The SMK shall be 256 bits. The pairwise key hierarchy takes an SMK and generates an STK. The STK is partitioned into SKCK, SKEK, and a temporal key, which is used by the MAC to protect individually addressed communication between the initiator and peer STAs. STKs are used between a single initiator STA and a single peer STA.

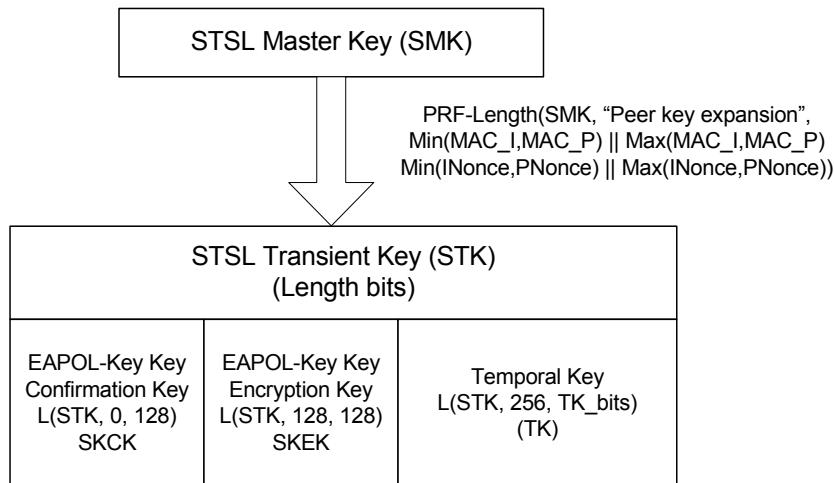

Figure 12-30—PeerKey hierarchy

The following apply and are depicted in Figure 12-30:

- a) INonce is a random or pseudorandom value contributed by the initiator STA.
- b) PNonce is a random or pseudorandom value contributed by the peer STA.
- c) The STK shall be derived from the SMK by

$$\text{STK} = \text{PRF-Length(SMK, "Peer key expansion", Min(MAC_I,MAC_P) || Max(MAC_I,MAC_P) || Min(INonce,PNonce) || Max(INonce,PNonce))}$$

where Length = 256 + TK_bits. The value of TK_bits is cipher-suite dependent and is defined in Table 12-4. The Min and Max operations for IEEE 802 addresses are with the address converted to a positive integer treating the first transmitted octet as the most significant octet of the integer. For the Min and Max operations, nonces are encoded as specified in 9.2.2.

- d) The SKCK shall be computed as the first 128 bits (bits 0–127) of the STK:

$$\text{SKCK} = L(\text{STK}, 0, 128)$$

The SKCK is used to provide data origin authenticity in the 4-way STK handshake.

- e) The SKEK shall be computed as bits 128–255 of the STK:

$$\text{SKEK} = L(\text{STK}, 128, 128)$$

The SKEK is used by the EAPOL-Key frames to provide confidentiality in the 4-way STK handshake.

- f) The temporal key (TK) shall be computed as bits 256 to (255 + TK_bits) of the STK:

$$\text{TK} = L(\text{STK}, 256, \text{TK_bits})$$

The EAPOL-Key state machines (see 12.7.10 and 12.7.11) use the MLME-SETKEYS.request primitive to configure the temporal key into the STA. The STA uses the temporal key with the pairwise cipher suite; interpretation of this value is cipher-suite-specific.

When the negotiated AKM is 00-0F-AC:5 or 00-0F-AC:6, the SMK identifier is defined as

$$\text{SMKID} = \text{Truncate-128}(\text{HMAC-SHA-256}(\text{SMK}, \text{"SMK Name"} \parallel \text{PNonce} \parallel \text{MAC_P} \parallel \text{INonce} \parallel \text{MAC_I}))$$

Otherwise, the SMK identifier is defined as

$$\text{SMKID} = \text{Truncate-128}(\text{HMAC-SHA-1}(\text{SMK}, \text{"SMK Name"} \parallel \text{PNonce} \parallel \text{MAC_P} \parallel \text{INonce} \parallel \text{MAC_I}))$$

In both these cases, “SMK Name” is treated as an ASCII string.

12.7.1.7 FT key hierarchy

12.7.1.7.1 Overview

This subclause describes the FT key hierarchy and its supporting architecture. The FT key hierarchy is designed to allow a STA to make fast BSS transitions between APs without the need to perform an SAE or IEEE 802.1X authentication at every AP within the mobility domain.

The FT key hierarchy can be used with SAE, IEEE 802.1X authentication, or PSK authentication.

A three-level key hierarchy provides key separation between the key holders. The FT key hierarchy for the Authenticator is shown in Figure 12-31. An identical key hierarchy exists for the Supplicant, and identical functions are performed by the corresponding S0KH and S1KH.

The FT key hierarchy shown in Figure 12-31 consists of three levels whose keys are derived using the key derivation function (KDF) described in 12.7.1.7.2 as follows:

- a) PMK-R0 – the first-level key of the FT key hierarchy. This key is derived as a function of the master session key (MSK) or PSK. It is stored by the PMK-R0 key holders, R0KH and S0KH.
- b) PMK-R1 – the second-level key of the FT key hierarchy. This key is mutually derived by the S0KH and R0KH.
- c) PTK – the third-level key of the FT key hierarchy that defines the IEEE 802.11 and IEEE 802.1X protection keys. The PTK is mutually derived by the PMK-R1 key holders, R1KH and S1KH.

As shown in Figure 12-31, the R0KH computes the PMK-R0 from the key obtained from SAE authentication (for the purposes of FT this key is identified as the Master PMK, or MPMK), from the PSK, or from the MSK resulting (per IETF RFC 3748 [B42]) from a successful IEEE 802.1X authentication between the AS and the Supplicant. Upon a successful authentication, the R0KH shall delete any prior PMK-R0 security association for this mobility domain pertaining to this S0KH. The R0KH shall also delete all PMK-R1 security associations derived from that prior PMK-R0 security association. The PMK-R1s are generated by the R0KH and are assumed to be delivered from the R0KH to the R1KHs within the same mobility domain. The PMK-R1s are used for PTK generation. Upon receiving a new PMK-R1 for an S0KH, an R1KH deletes the prior PMK-R1 security association and PTKSAs derived from the prior PMK-R1.

It is assumed by this standard that the PSK is specific to a single S0KH and a single R0KH.

The lifetime of the PMK-R0, PMK-R1, and PTK are bound to the lifetime of the MPMK, PSK, or MSK from which it was derived. For example, the AS may communicate the MSK lifetime with the MSK. If such an attribute is provided, the lifetime of the PMK-R0 shall be not more than the lifetime of the MSK. The lifetime of the PTK and PMK-R1 is the same as that of the PMK-R0. When the key lifetime expires, each key holder shall delete its respective PMK-R0, PMK-R1 or PTKSA.

The FT key hierarchy derives its keys using the KDF defined in 12.7.1.7.2 with separate labels to further distinguish derivations.

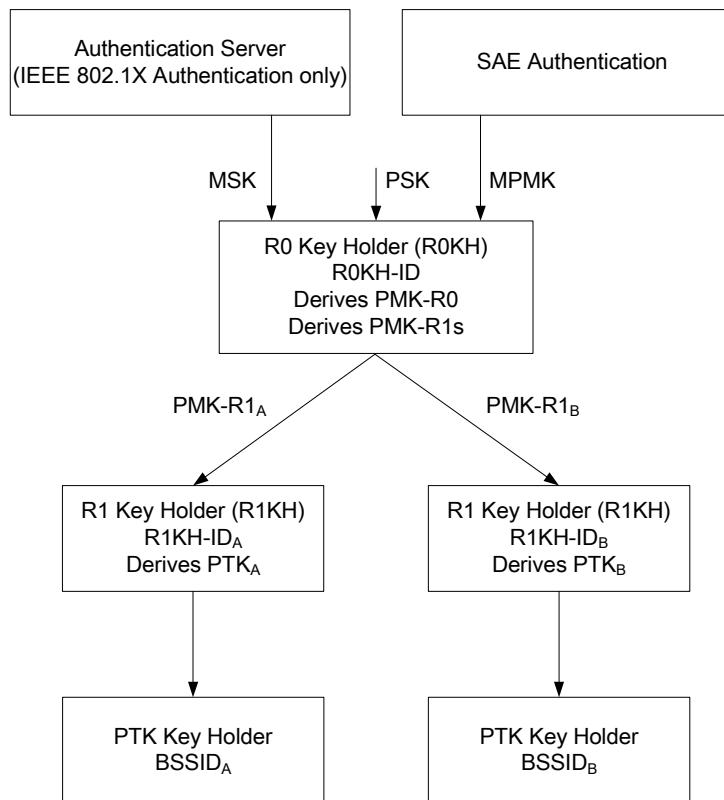

Figure 12-31—FT key hierarchy at an Authenticator

During a fast BSS transition, a STA shall negotiate the same pairwise cipher suite with target APs as was negotiated in the FT initial mobility domain association. Using the pairwise cipher suite selector value in the PMK-R1 security association received from the R0KH, the target AP shall verify that the same pairwise cipher suite selector is being used.

The distribution of keys from the R0KH to the R1KHS is outside the scope of this standard. It is assumed that the PMK-R1s are distributed from the R0KH to the R1KHS following the requirements specified in 13.2.2.

The PMK-R0 may be deleted by the R0KH after PMK-R1s have been derived. When the PMK-R0 is deleted, the R0KH needs only to maintain the PMK-R1 security associations.

12.7.1.7.2 Key derivation function (KDF)

The KDF is a variant of the pseudorandom function (PRF) defined in 12.7.1.2 and is defined as follows:

Output \leftarrow KDF-Hash-Length (K, Label, Context) where

Input: *K*, a derivation key whose length equals the block size of the hash function

Hash, a cryptographically strong hash function

Label, a string identifying the purpose of the keys derived using this KDF, treated as an ASCII string

Context, a bit string that provides context to identify the derived key

Length, the length of the derived key in bits

Output: a *Length*-bit derived key

```

result ← ""
iterations ← ⌈Length/Hashlen⌉
do i = 1 to iterations
    result ← result || HMAC-Hash(K, i || Label || Context || Length)
od
return first Length bits of result, and irretrievably delete the other bits

```

where

i and *Length* are encoded as 16-bit unsigned integers, represented using the bit ordering conventions of 9.2.2

K, *Label*, and *Context* are bit strings and are represented using the ordering conventions of 9.2.2
Hashlen is the length, in bits, of the digest produced by Hash

12.7.1.7.3 PMK-R0

The first-level key in the FT key hierarchy, PMK-R0, is derived using the KDF defined in 12.7.1.7.2. The PMK-R0 is the first level keying material used to derive the next level keys (PMK-R1s):

```

R0-Key-Data = KDF-Hash-Length(XXKey, "FT-R0", SSIDlength || SSID || MDID || R0KHlength ||
                           R0KH-ID || S0KH-ID)
PMK-R0 = L(R0-Key-Data, 0, Q)
PMK-R0Name-Salt = L(R0-Key-Data, Q, 128)
Length = Q + 128

```

where

- KDF-Hash-Length is the KDF as defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133).
- If the AKM negotiated is 00-0F-AC:3, then Q shall be 256, and XXKey shall be the second 256 bits of the MSK (which is derived from the IEEE 802.1X authentication), i.e., XXKey = L(MSK, 256, 256). If the AKM negotiated is 00-0F-AC:4, then Q shall be 256, and XXKey shall be the PSK. If the AKM negotiated is 00-0F-AC:9, then Q shall be 256, and XXKey shall be the MPMK generated as the result of SAE authentication. If the AKM negotiated is 00-0F-AC:13, then Q shall be 384, and XXKey shall be the first 384 bits of the MSK (which is derived from the IEEE 802.1X authentication), i.e., XXKey = L(MSK, 0, 384).
- SSIDlength is a single octet whose value is the number of octets in the SSID.
- SSID is the service set identifier, a variable-length sequence of octets, as it appears in the Beacon and Probe Response frames.
- MDID is the Mobility Domain Identifier field from the Mobile Domain element (MDE) that was used during FT initial mobility domain association.
- R0KHlength is a single octet whose value is the number of octets in the R0KH-ID.
- R0KH-ID is the identifier of the holder of PMK-R0 in the Authenticator.
- S0KH-ID is the Supplicant's MAC address (SPA).

The PMK-R0 is referenced and named as follows:

PMKR0Name = Truncate-128(SHA-256("FT-R0N" || PMK-R0Name-Salt))

where

- "FT-R0N" is treated as an ASCII string.

The PMKR0Name is used to identify the PMK-R0.

12.7.1.7.4 PMK-R1

The second-level key in the FT key hierarchy, PMK-R1, is a key used to derive the PTK. The PMK-R1 is derived using the KDF defined in 12.7.1.7.2:

$$\text{PMK-R1} = \text{KDF-Hash-Length}(\text{PMK-R0}, \text{"FT-R1"}, \text{R1KH-ID} \parallel \text{S1KH-ID})$$

where

- KDF-Hash-Length is the KDF as defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133) to generate a key whose length is equal to the length of the hash algorithm's digest.
- PMK-R0 is the first level key in the FT key hierarchy.
- R1KH-ID is a MAC address of the holder of the PMK-R1 in the Authenticator of the AP.
- S1KH-ID is the SPA.

The PMK-R1 is referenced and named as follows:

$$\text{PMKR1Name} = \text{Truncate-128}(\text{SHA-256}(\text{"FT-R1N"} \parallel \text{PMKR0Name} \parallel \text{R1KH-ID} \parallel \text{S1KH-ID}))$$

where

- "FT-R1N" is treated as an ASCII string.

PMKR1Name is used to identify the PMK-R1.

12.7.1.7.5 PTK

The third-level key in the FT key hierarchy is the PTK. This key is mutually derived by the S1KH and the R1KH used by the target AP, with the key length being a function of the negotiated cipher suite as defined by Table 12-4 in 12.7.2.

Using the KDF defined in 12.7.1.7.2, the PTK derivation is as follows:

$$\text{PTK} = \text{KDF-Hash-Length}(\text{PMK-R1}, \text{"FT-PTK"}, \text{SNonce} \parallel \text{ANonce} \parallel \text{BSSID} \parallel \text{STA-ADDR})$$

where

- KDF-Hash-Length is the KDF as defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133).
- PMK-R1 is the key that is shared between the S1KH and the R1KH.
- SNonce is a 256-bit random bit string contributed by the S1KH.
- ANonce is a 256-bit random bit string contributed by the R1KH.
- STA-ADDR is the non-AP STA's MAC address.
- BSSID is the BSSID of the target AP.
- Length is the total number of bits to derive, i.e., number of bits of the PTK. The length is dependent on the negotiated cipher suites and AKM suites as defined by Table 12-4 in 12.7.2 and Table 12-8 in 12.7.3.

Each PTK has three component keys, KCK, KEK, and a temporal key, derived as follows:

The KCK shall be computed as the first KCK_bits bits (bits 0 to KCK_bits-1) of the PTK:

$$KCK = L(PTK, 0, KCK_bits).$$

The KCK is used to provide data origin authenticity in EAPOL-Key frames, as defined in 12.7.2, and in the FT authentication sequence, as defined in 13.8.

The KEK shall be computed as the next KEK_bits of the PTK:

$$KEK = L(PTK, KCK_bits, KEK_bits)$$

The KEK is used to provide data confidentiality for certain fields (KeyData) in EAPOL-Key frames, as defined in 12.7.2, and in the FT authentication sequence, as defined in 13.8.

The temporal key (TK) shall be computed as the next TK_bits (see Table 12-4) bits of the PTK:

$$TK = L(PTK, KCK_bits+KEK_bits, TK_bits)$$

For vendor-specific cipher suites, the length of the temporal key (and the value of Length) depend on the vendor-specific algorithm.

The temporal key is configured into the STA by the SME through the use of the MLME-SETKEYS.request primitive. The STA uses the temporal key with the pairwise cipher suite; interpretation of this value is specific to the cipher suite.

The PTK is referenced and named as follows:

$$PTKName = \text{Truncate-128}(\text{SHA-256}(PMKR1Name \parallel "FT-PTKN" \parallel SNonce \parallel ANonce \parallel BSSID \parallel STA-ADDR))$$

where

- "FT-PTKN" is treated as an ASCII string.

The PTKName is used to identify the PTK.

12.7.2 EAPOL-Key frames

IEEE Std 802.11 uses EAPOL-Key frames to exchange information between STAs' Supplicants and Authenticators. These exchanges result in cryptographic keys and synchronization of security association state. EAPOL-Key frames are used to implement three different exchanges:

- 4-way handshake, to confirm that the PMK between associated STAs is the same and live and to transfer the GTK to the STA.
- Group key handshake, to update the GTK at the STA.
- PeerKey initial SMK handshake to deliver the SMK and final 4-way STK handshake to deliver the STK to the initiating and peer STAs.

When priority processing of Data frames is supported, an SME should send EAPOL-Key frames at the highest priority.

The RSNA key descriptor used by IEEE Std 802.11 maps to the IEEE 802.1X Key Descriptor as described in this subclause.

The bit and octet convention for fields in the EAPOL-Key frame are defined in 11.2 of IEEE Std 802.1X-2010. EAPOL-Key frames containing invalid field values shall be silently discarded. Figure 12-32 depicts the format of an EAPOL-Key frame.

| | | |
|-------------------------------|-----------------------|-------------------------------|
| Protocol Version – 1 octet | Packet Type – 1 octet | Packet Body Length – 2 octets |
| Descriptor Type – 1 octet | | |
| Key Information – 2 octets | Key Length – 2 octets | |
| Key Replay Counter – 8 octets | | |
| KeyNonce – 32 octets | | |
| EAPOL - Key IV – 16 octets | | |
| Key RSC – 8 octets | | |
| Reserved – 8 octets | | |
| Key MIC – variable | | |
| Key Data Length – 2 octets | Key Data – n octets | |

Figure 12-32—EAPOL-Key frame

The fields of an EAPOL-Key frame body are as follows:

- a) **Descriptor Type.** This field is 1 octet and has a value defined by IEEE Std 802.1X-2010, identifying the IEEE 802.11 key descriptor.
- b) **Key Information.** This field is 2 octets and specifies characteristics of the key. See Figure 12-33.

| B0 | B2 | B3 | B4 | B5 | B6 | B7 | B8 | B9 | B10 | B11 | B12 | B13 | B14 | B15 |
|------------------------|----------|----------|---------|---------|---------|-------------|-------|---------|--------------------|-------------|----------|-----|-----|-----|
| Key Descriptor Version | Key Type | Reserved | Install | Key Ack | Key MIC | Se- cure | Error | Request | Encrypted Key Data | SMK Message | Reserved | | | |

Figure 12-33—Key Information bit layout

The bit convention used is as in 11.2 of IEEE Std 802.1X-2010. The subfields of the Key Information field are as follows:

- 1) Key Descriptor Version (bits 0–2) shall be set to 0 on all transmitted EAPOL-Key frames except under the following circumstances:
 - i) The value 1 shall be used for all EAPOL-Key frames to a STA when the negotiated AKM is 00-0F-AC:1 or 00-0F-AC:2 and the pairwise cipher is TKIP or "Use group cipher suite" for Key Descriptor 1. This value indicates the following:
 - HMAC-MD5 is the EAPOL-Key MIC.
 - ARC4 is the EAPOL-Key encryption algorithm used to protect the Key Data field.
 - The MIC is 16 octets.
 - ii) The value 2 shall be used for all EAPOL-Key frames to a STA when the negotiated AKM is 00-0F-AC:1 or 00-0F-AC:2 and either the pairwise or the group cipher is an enhanced

data cryptographic encapsulation mechanism other than TKIP for Key Descriptor 2. This value indicates the following:

- HMAC-SHA-1-128 is the EAPOL-Key MIC. HMAC is defined in IETF RFC 2104; and SHA-1, by FIPS PUB 180-4. The output of the HMAC-SHA-1 shall be truncated to its 128 MSBs (octets 0–15 of the digest output by HMAC-SHA-1), i.e., the last four octets generated shall be irretrievably deleted).
 - The NIST AES key wrap is the EAPOL-Key encryption algorithm used to protect the Key Data field. IETF RFC 3394 defines the NIST AES key wrap algorithm.
 - The MIC is 16 octets.
- iii) The value 3 shall be used for all EAPOL-Key frames to a STA when the negotiated AKM is 00-0F-AC:3, 00-0F-AC:4, 00-0F-AC:5, or 00-0F-AC:6. This value indicates the following:
- AES-128-CMAC is the EAPOL-Key MIC. AES-128-CMAC is defined by NIST Special Publication 800-38B and also found in IETF RFC 4493. The output of the AES-128-CMAC shall be 128 bits.
 - The NIST AES key wrap is the EAPOL-Key encryption algorithm used to protect the Key Data field. IETF RFC 3394 defines the NIST AES key wrap algorithm.
 - The MIC is 16 octets.
- 2) Key Type (bit 3) specifies whether this EAPOL-Key frame is part of a 4-way handshake deriving a PTK.
- i) The value 0 (Group/SMK) indicates the message is not part of a PTK derivation.
 - ii) The value 1 (Pairwise) indicates the message is part of a PTK derivation.
- 3) Reserved (bits 4–5).
- 4) Install (bit 6).
- i) If the value of Key Type (bit 3) is 1, then for the Install bit,
 - The value 1 means the IEEE 802.1X component shall configure the temporal key derived from this message into its IEEE 802.11 STA.
 - The value 0 means the IEEE 802.1X component shall not configure the temporal key into the IEEE 802.11 STA.
 - ii) If the value of Key Type (bit 3) is 0, then this bit is reserved.
- 5) Key Ack (bit 7) is set to 1 in messages from the Authenticator if an EAPOL-Key frame is required in response to this message and is 0 otherwise. The Supplicant’s response to this message shall use the same replay counter as this message.
- 6) Key MIC (bit 8) is set to 1 if a MIC is in this EAPOL-Key frame and is set to 0 if this message contains no MIC.
- 7) Secure (bit 9) is set to 1 once the initial key exchange is complete.
- The Authenticator shall set the Secure bit to 0 in all EAPOL-Key frames sent before the Supplicant has the PTK and the GTK. The Authenticator shall set the Secure bit to 1 in all EAPOL-Key frames it sends to the Supplicant containing the last key needed to complete the Supplicant’s initialization.
- The Supplicant shall set the Secure bit to 0 in all EAPOL-Key frames it sends before it has the PTK and the GTK and before it has received an EAPOL-Key frame from the Authenticator with the Secure bit equal to 1 (this should be before receiving message 3 of the 4-way handshake). The Supplicant shall set the Secure bit to 1 in all EAPOL-Key frames sent after this until it loses the security association it shares with the Authenticator.
- 8) Error (bit 10) is set by a Supplicant to report that a MIC failure occurred in a TKIP MSDU or SMK handshake failure. In case of a MIC failure, a Supplicant shall set this bit to 1 only when

the Request (bit 11) is 1. When the SMK Message bit is 1, Error shall be set to 1 to indicate the key data field contains an Error KDE.

- 9) Request (bit 11) is set to 1 by a Supplicant to request that the Authenticator initiate either a 4-way handshake or group key handshake, is set to 1 by a Supplicant in a Michael MIC Failure Report, and is set to 1 by the STSL peer STA to request initiator STA rekeying of the STK. The Supplicant shall not set this bit to 1 in on-going 4-way handshakes, i.e., the Key Ack bit (bit 7) shall not be set to 1 in any message in which the Request bit is 1. The Authenticator shall never set this bit to 1.

In a Michael MIC Failure Report, setting the bit is not a request to initiate a new handshake. However, the recipient may initiate a new handshake on receiving such a message.

If an EAPOL-Key frame in which the Request bit is 1 has a key type of Pairwise, the Authenticator shall initiate a 4-way handshake. If the EAPOL-Key frame in which the Request bit is 1 has a key type of Group/SMK, the Authenticator shall change the GTK, initiate a 4-way handshake with the Supplicant, and then execute the group key handshake to all Supplicants.

If an EAPOL-Key frame in which the Request bit is 1 has the SMK Message bit equal to 1, the initiator STA shall take appropriate action to create a new STK (based on 12.7.8).

- 10) Encrypted Key Data (bit 12) is set to 1 if the Key Data field is encrypted and is set to 0 if the Key Data field is not encrypted. This subfield shall be set to 1, and the Key Data field shall be encrypted, if any key material (e.g., GTK or SMK) is included in the frame.
 - 11) SMK Message (bit 13) specifies whether this EAPOL-Key frame is part of an SMK handshake. If the SMK handshake is not supported, the SMK Message subfield is reserved.
 - 12) Reserved (bits 14–15).
- c) **Key Length.** This field is 2 octets in length, represented as an unsigned integer. The value defines the length in octets of the pairwise temporal key. See Table 12-4.

Table 12-4—Cipher suite key lengths

| Cipher suite | Key length (octets) | TK bits (bits) |
|--------------|---------------------|----------------|
| WEP-40 | 5 | 40 |
| WEP-104 | 13 | 104 |
| TKIP | 32 | 256 |
| CCMP-128 | 16 | 128 |
| BIP-CMAC-128 | 16 | 128 |
| GCMP-128 | 16 | 128 |
| GCMP-256 | 32 | 256 |
| CCMP-256 | 32 | 256 |
| BIP-GMAC-128 | 16 | 128 |
| BIP-GMAC-256 | 32 | 256 |
| BIP-CMAC-256 | 32 | 256 |

- d) **Key Replay Counter.** This field is 8 octets, represented as an unsigned integer, and is initialized to 0 when the PMK is established. The Supplicant shall use the key replay counter in the received

EAPOL-Key frame when responding to an EAPOL-Key frame. It carries a sequence number that the protocol uses to detect replayed EAPOL-Key frames.

The Supplicant and Authenticator shall track the key replay counter per security association. The key replay counter shall be initialized to 0 on (re)association. The Authenticator shall increment the key replay counter on each successive EAPOL-Key frame.

When replying to a message from the Authenticator, the Supplicant shall use the Key Replay Counter field value from the last valid EAPOL-Key frames received from the Authenticator. The Authenticator should use the key replay counter to identify invalid messages to silently discard. The Supplicant should also use the key replay counter and ignore EAPOL-Key frames with a Key Replay Counter field value smaller than or equal to any received in a valid message. The local Key Replay Counter field should not be updated until after the EAPOL-Key MIC is checked and is found to be valid. In other words, the Supplicant never updates the Key Replay Counter field for message 1 in the 4-way handshake, as it includes no MIC. This implies the Supplicant needs to allow for retransmission of message 1 when checking for the key replay counter of message 3.

The Supplicant shall maintain a separate key replay counter for sending EAPOL-Key request frames to the Authenticator; the Authenticator also shall maintain a separate replay counter to filter received EAPOL-Key request frames.

NOTE—The key replay counter does not play any role beyond a performance optimization in the 4-way handshake. In particular, replay protection is provided by selecting a never-before-used nonce value to incorporate into the PTK. It does, however, play a useful role in the group key handshake.

- e) **Key Nonce.** This field is 32 octets. It conveys the ANonce from the Authenticator and the SNonce from the Supplicant. It may contain 0 if a nonce is not required to be sent.
- f) **EAPOL-Key IV.** This field is 16 octets. It contains the IV used with the KEK. It shall contain 0 when an IV is not required. It should be initialized by taking the current value of the global key counter (see 12.7.11) and then incrementing the counter. Note that only the lower 16 octets of the counter value are used.
- g) **Key RSC.** This field is 8 octets in length. It contains the receive sequence counter (RSC) for the GTK being installed. It is used in message 3 of the 4-way handshake and message 1 of the group key handshake, where it is used to synchronize the IEEE 802.11 replay state. It may also be used in the Michael MIC Failure Report frame, to report the TSC field value of the frame experiencing a MIC failure. It shall contain 0 in other messages. The Key RSC field gives the current message number for the GTK, to allow a STA to identify replayed MPDUs. If the Key RSC field value is less than 8 octets in length, the remaining octets shall be set to 0. The least significant octet of the TSC or PN should be in the first octet of the Key RSC field. The encoding of the Key RSC field is defined in Table 12-5.

Table 12-5—Key RSC field

| KeyRSC 0 | KeyRSC 1 | KeyRSC 2 | KeyRSC 3 | KeyRSC 4 | KeyRSC 5 | KeyRSC 6 | KeyRSC 7 |
|----------|----------|----------|----------|----------|----------|----------|----------|
| TSC0 | TSC1 | TSC2 | TSC3 | TSC4 | TSC5 | 0 | 0 |
| PN0 | PN1 | PN2 | PN3 | PN4 | PN5 | 0 | 0 |

For WEP, the Key RSC field is reserved.

- h) **Key MIC.** The EAPOL Key MIC is a MIC of the EAPOL-Key frames, from and including the EAPOL protocol version field to and including the Key Data field, calculated with the Key MIC field set to 0. If the Encrypted Key Data subfield (of the Key Information field) is 1, the Key Data field is encrypted prior to computing the MIC. The length of this field depends on the negotiated AKM as defined in 12.7.3.

- i) **Key Data Length.** This field is 2 octets in length, taken to represent an unsigned integer. This represents the length of the Key Data field in octets. If the Encrypted Key Data subfield (of the Key Information field) is 1, the length is the length of the Key Data field after encryption, including any padding.
- j) **Key Data.** This field is a variable-length field that is used to include any additional data required for the key exchange that is not included in the fields of the EAPOL-Key frame. The additional data may be zero or more element(s) (such as the RSNE) and zero or more key data cryptographic encapsulation(s) (KDEs) (such as GTK(s) or PMKID(s)). Elements sent in the Key Data field include the Element ID and Length subfields. KDEs shall be encapsulated using the format in Figure 12-34.

| Type (0xdd) | Length | OUI | Data Type | Data |
|-------------|--------|-----|-----------|-------------------|
| Octets: | 1 | 1 | 3 | 1 (Length – 4) |

Figure 12-34—KDE format

The Type field shall be set to 0xdd. The Length field specifies the number of octets in the OUI, Data Type, and Data fields. The OUI field contains either an OUI or CID. The order of the OUI field is described in 9.2.2.

Table 12-6 lists the KDE selectors defined by this standard.

Table 12-6—KDE

| OUI | Data type | Meaning |
|------------------|-----------|-----------------------|
| 00-0F-AC | 0 | Reserved |
| 00-0F-AC | 1 | GTK KDE |
| 00-0F-AC | 2 | Reserved |
| 00-0F-AC | 3 | MAC address KDE |
| 00-0F-AC | 4 | PMKID KDE |
| 00-0F-AC | 5 | SMK KDE |
| 00-0F-AC | 6 | Nonce KDE |
| 00-0F-AC | 7 | Lifetime KDE |
| 00-0F-AC | 8 | Error KDE |
| 00-0F-AC | 9 | IGTK KDE |
| 00-0F-AC | 10 | Key ID KDE |
| 00-0F-AC | 11 | Multi-band GTK KDE |
| 00-0F-AC | 12 | Multi-band Key ID KDE |
| 00-0F-AC | 13–255 | Reserved |
| Other OUI or CID | Any | Vendor specific |

A STA shall ignore any elements and KDEs it does not understand.

If the Encrypted Key Data subfield (of the Key Information field) is 1, the entire Key Data field shall be encrypted. If the Key Data field uses the NIST AES key wrap, then the Key Data field shall be padded before encrypting if the key data length is less than 16 octets or if it is not a multiple of 8.

The padding consists of appending a single octet 0xdd followed by zero or more 0x00 octets. When processing a received EAPOL-Key frame, the receiver shall ignore this trailing padding. Key Data fields that are encrypted, but do not contain the GroupKey or SMK KDE, shall be accepted.

If the GroupKey or SMK KDE is included in the Key Data field, but the Key Data field is not encrypted, the EAPOL-Key frames shall be ignored.

The format of the GTK KDE is shown in Figure 12-35

| Key ID | Tx | Reserved | Reserved | GTK |
|----------|-------|----------|----------|---------------------|
| bits 0–1 | bit 2 | bit 3–7 | 1 octet | (Length – 6) octets |

Figure 12-35—GTK KDE format

If the value of the Tx field is 1, then the IEEE 802.1X component shall configure the temporal key derived from this KDE into its IEEE 802.11 STA for both transmission and reception.

If the value of the Tx field is 0, then the IEEE 802.1X component shall configure the temporal key derived from this KDE into its IEEE 802.11 STA for reception only.

The format of the MAC address KDE is shown in Figure 12-36.

Octets: 6

Figure 12-36—MAC address KDE format

The format of the PMKID KDE is shown in Figure 12-37.

Octets: 16

Figure 12-37—PMKID KDE format

The format of the SMK KDE is shown in Figure 12-38.

Octets: 32 32

Figure 12-38—SMK KDE format

The format of the Nonce KDE is shown in Figure 12-39.

Octets: 32

Figure 12-39—Nonce KDE format

The format of the Lifetime KDE is shown in Figure 12-40. The Key Lifetime value is expressed in seconds and uses big endian octet order.

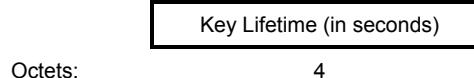

Figure 12-40—Lifetime KDE format

The format of the Error KDE is shown in Figure 12-41. The Error Type field is in big endian octet order. Table 12-7 shows different values of SMK error types.

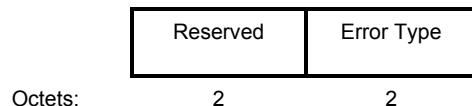

Figure 12-41—Error KDE format

Table 12-7—SMK error types

| Error name | Error type | Error meaning |
|--------------|------------|---|
| ERR_STA_NR | 1 | STA is not reachable from AP. See 12.7.8.5.2. |
| ERR_STA_NRSN | 2 | STA to AP secure network not present. See 12.7.8.5.3. |
| ERR_CPHR_NS | 3 | Cipher suites not supported. See 12.7.8.5.4. |
| ERR_NO_STSL | 4 | No STSL session present. See 12.7.8.5.5. |

The format of the IGTK KDE is shown in Figure 12-42. The IPN corresponds to the last packet number used by the broadcast/multicast transmitter, and it is used by the receiver as the initial value for the BIP replay counter.

Figure 12-42—IGTK KDE format

The following EAPOL-Key frames are used to implement the three different exchanges:

- **4-way handshake message 1** is an EAPOL-Key frame with the Key Type subfield equal to 1. The Key Data field shall contain a PMKID for the PMK that is being used in this key derivation and need not be encrypted.
- **4-way handshake message 2** is an EAPOL-Key frame with the Key Type subfield equal to 1. The Key Data field shall contain an RSNE and need not be encrypted.

An ESS Supplicant’s SME shall insert the RSNE it sent in its (Re)Association Request frame. The RSNE is included as transmitted in the Management frame. On receipt of message 2, the Authenticator’s SME shall validate the selected security configuration against the RSNE received in the IEEE 802.11 (Re)Association Request.

An IBSS Supplicant’s SME shall insert an RSNE containing a selected pairwise cipher suite. The Authenticator’s SME shall validate that the pairwise cipher suite selected is one of its configured cipher suites and that the group cipher suite and AKM are consistent.

- **4-way handshake message 3** is an EAPOL-Key frame with the Key Type subfield equal to 1. The Key Data field shall contain one or two RSNEs. If a group cipher has been negotiated, this field shall also include a GTK. This field shall be encrypted if a GTK is included.

An Authenticator's SME shall insert the RSNE it sent in its Beacon or Probe Response frame. The Supplicant's SME shall validate the selected security configuration against the RSNE received in message 3. If the second optional RSNE is present, the STA shall either use that cipher suite with its pairwise key or deauthenticate. In either case, if the values do not match, then the receiver shall consider the RSNE modified and shall use the MLME-DEAUTHENTICATE.request primitive to break the association. A security error should be logged at this time.

It may happen, for example, that a Supplicant selects a pairwise cipher suite which is advertised by an AP, but which policy disallows for this particular STA. An Authenticator may, therefore, insert a second RSNE to overrule the STA's selection. An Authenticator's SME shall insert the second RSNE, after the first RSNE, only for this purpose. The pairwise cipher suite in the second RSNE included shall be one of the ciphers advertised by the Authenticator. All other fields in the second RSNE shall be identical to the first RSNE.

A GTK shall be included and the unencrypted length of the GTK is six less than the length of the GTK KDE in octets. The entire Key Data field shall be encrypted as specified by the Key Descriptor Version.

- **4-way handshake message 4** is an EAPOL-Key frame with the Key Type subfield equal to 1. The Key Data field can be empty.
- **Group key handshake message 1** is an EAPOL-Key frame with the Key Type subfield equal to 0. The Key Data field shall contain a GTK KDE and shall be encrypted.
- **Group key handshake message 2** is an EAPOL-Key frame with the Key Type subfield equal to 0. The Key Data field can be empty.

PeerKey handshake messages use EAPOL-Key frames as defined in 12.7.8.

The key wrap algorithm selected depends on the negotiated AKM as defined in 12.7.3.

The format of the Key ID KDE is shown in Figure 12-43.

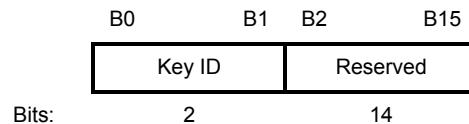

Figure 12-43—Key ID KDE

The Key ID field contains the Authenticator selected Key ID.

The format of the Multi-band GTK KDE is shown in Figure 12-44.

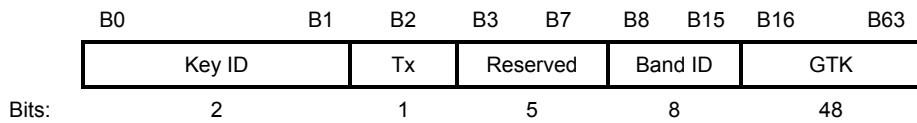

Figure 12-44—Multi-band GTK KDE

The definitions of the Key ID, Tx, and GTK fields are the same as in the GTK KDE described above.

The Band ID field contains the identification of the frequency band (see 9.4.1.46).

The format of the Multi-band Key ID KDE is shown in Figure 12-45.

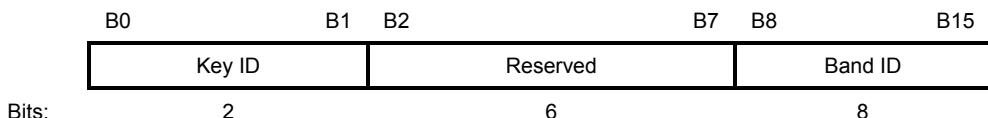

Figure 12-45—Multi-band Key ID KDE

The definitions of the Key ID and Band ID fields are the same as in the Multi-band GTK KDE described above.

12.7.3 EAPOL-Key frame construction and processing

EAPOL-Key frames are constructed and processed according to the AKM negotiated at association time. The negotiated AKM determines what algorithm is used to construct and verify a MIC, the size of the MIC, and the algorithm used to wrap and unwrap the Key Data field.

Table 12-8 indicates the particular algorithms to use when constructing and processing EAPOL-Key frames. The AKM of “Deprecated” indicates an AKM of 00-0F-AC:1 or 00-0F-AC:2 when either TKIP or “Use group cipher suite” is the negotiated pairwise cipher. For all other AKMs the negotiated pairwise cipher suite does not influence the algorithms used to process EAPOL-Key frames.

Table 12-8—Integrity and key-wrap algorithms

| AKM | Integrity algorithm | KCK_bits | Size of MIC | Key-wrap algorithm | KEK_bits |
|-------------|---------------------|----------|-------------|--------------------|----------|
| 00-0F-AC:1 | HMAC-SHA-1-128 | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:2 | HMAC-SHA-1-128 | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:3 | AES-128-CMAC | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:4 | AES-128-CMAC | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:5 | AES-128-CMAC | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:6 | AES-128-CMAC | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:8 | AES-128-CMAC | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:9 | AES-128-CMAC | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:11 | HMAC-SHA-256 | 128 | 16 | NIST AES Key Wrap | 128 |
| 00-0F-AC:12 | HMAC-SHA-384 | 192 | 24 | NIST AES Key Wrap | 256 |
| 00-0F-AC:13 | HMAC-SHA-384 | 192 | 24 | NIST AES Key Wrap | 256 |

12.7.4 EAPOL-Key frame notation

The following notation is used throughout the remainder of 12.7 and 13.4 to represent EAPOL-Key frames:

EAPOL-Key(S, M, A, I, K, SM, KeyRSC, ANonce/SNonce, MIC, DataKDs)

where

| | |
|-------------------|--|
| S | means the initial key exchange is complete. This is the Secure bit of the Key Information field. |
| M | means the MIC is available in message. This should be set in all messages except message 1 of a 4-way handshake. This is the Key MIC bit of the Key Information field. |
| A | means a response is required to this message. This is used when the receiver should respond to this message. This is the Key Ack bit of the Key Information field. |
| I | is the Install bit: Install/Not install for the pairwise key. This is the Install bit of the Key Information field. |
| K | is the key type: P (Pairwise), G (Group/SMK). This is the Key Type bit of the Key Information field. |
| SM | is the SMK Message bit: indicates that this message is part of SMK handshake. |
| KeyRSC | is the key RSC. This is the Key RSC field. |
| ANonce/SNonce | is the Authenticator/Supplicant nonce. This is the Key Nonce field. |
| MIC | is the integrity check, which is generated using the KCK. This is the Key MIC field. |
| DataKDs | is a sequence of zero or more elements and KDEs, contained in the Key Data field, which may contain the following: |
| RSNE | is described in 9.4.2.25. |
| RSNE[KeyName] | is the RSNE, with the PMKID field set to KeyName. |
| GTK[N] | is the GTK, with the key identifier field set to N. The key identifier specifies which index is used for this GTK. Index 0 shall not be used for GTKs, except in mixed environments, as described in 12.7.1. |
| FTE | is the Fast BSS Transition element, described in 9.4.2.48 |
| MDE | is the Mobility Domain element, described in 9.4.2.47 |
| TIE[IntervalType] | is a Timeout Interval element of type IntervalType, as described in 9.4.2.49, containing e.g., for type KeyLifetime, the lifetime of the FT key hierarchy. |
| IGTK[M] | is the IGTK, with key identifier field set to M. |
| IPN | is the current IGTK replay counter value provided by the IGTK KDE |
| PMKID | is of type PMKID KDE and is the key identifier used during 4-way PTK handshake for PMK identification and during 4-way STK handshake for SMK identification. |
| Lifetime | is the key lifetime KDE used for sending the expiration timeout value for SMK used during PeerKey handshake for SMK identification. |
| Initiator MAC | is the Initiator MAC KDE used during PeerKey handshake |
| Peer MAC | is the Peer MAC KDE used during PeerKey handshake |
| InitiatorNonce | is the Initiator Nonce KDE used during PeerKey handshake. This is used when multiple nonces need to be sent. |
| PeerNonce | is the Peer Nonce KDE used during PeerKey handshake. This is used when multiple nonces need to be sent. |
| SMK KDE | is the SMK during SMK handshake. |
| Error KDE | is an error KDE used when error bit E is equal to 1 during PeerKey handshake. |

12.7.5 Nonce generation

The following is an informative description of Nonce generation.

All STAs contain a global key counter, which is 256 bits in size. It should be initialized at system boot-up time to a fresh cryptographic-quality random number. Refer to J.5 on random number generation. It is recommended that the counter value is initialized to the following:

PRF-256(Random number, “Init Counter”, Local MAC Address || Time)

The local MAC address should be AA on the Authenticator and SPA on the Supplicant.

The random number is 256 bits in size. Time should be the current time from Network Time Protocol (NTP) or another time in NTP format whenever possible. This initialization causes different initial key counter values to occur across system restarts regardless of whether a real-time clock is available. The key counter can be used as additional input data for nonce generation. A STA derives a random nonce for each new use.

12.7.6 4-way handshake

12.7.6.1 General

RSNA defines a protocol using EAPOL-Key frames called the *4-way handshake*. The handshake completes the IEEE 802.1X authentication process. The information flow of the 4-way handshake is as follows:

- Message 1: Authenticator → Supplicant: EAPOL-Key(0,0,1,0,P,0,0,ANonce,0,DataKD_M1)
where DataKD_M1 = 0 or PMKID for PTK generation, or PMKID KDE (for sending SMKID) for STK generation
- Message 2: Supplicant → Authenticator: EAPOL-Key(0,1,0,0,P,0,0,SNonce,MIC,DataKD_M2)
where DataKD_M2 = RSNE for creating PTK generation or peer RSNE, Lifetime KDE, SMKID KDE (for sending SMKID) for STK generation
- Message 3: Authenticator → Supplicant:
EAPOL-Key(1,1,1,1,P,0,KeyRSC,ANonce,MIC,DataKD_M3)
where DataKD_M3 = RSNE, GTK[N] for creating PTK generation or initiator RSNE, Lifetime KDE for STK generation
- Message 4: Supplicant → Authenticator: EAPOL-Key(1,1,0,0,P,0,0,0,MIC,DataKD_M4)
where DataKD_M4 = 0.

The FT initial mobility domain association uses the FT 4-way handshake to establish an initial PTKSA, GTKSA and, if management frame protection is enabled, an IGTKSA, that is based on this protocol. The FT 4-way handshake protocol is described in 13.4.

Here, the following assumptions apply:

- EAPOL-Key() denotes an EAPOL-Key frame conveying the specified argument list, using the notation introduced in 12.7.4.
- ANonce is a nonce that the Authenticator contributes for PTK generation or that the initiator STA contributes for STK generation. ANonce has the same value in message 1 and message 3.
- SNonce is a nonce from the Supplicant for PTK generation or from the peer STA for STK generation.
- P means the pairwise bit is set.
- The MIC is computed over the body of the EAPOL-Key frame (with the Key MIC field first zeroed before the computation) using the KCK defined in 12.7.1.3 for PTK generation or SKCK defined in 12.7.1.6.
- RSNE represents the appropriate RSNEs.
- GTK[N] represents the GTK with its key identifier.
- SMKID represents the SMKID key identifier used during STK generation.
- Lifetime represents the expiration timeout used for exchanging SMK expiration value.

NOTE—While the MIC calculation is the same in each direction, the Key Ack bit is different in each direction. It is set in EAPOL-Key frames from the Authenticator and 0 in EAPOL-Key frames from the Supplicant. 4-way handshake requests from the Supplicant have the Request bit equal to 1. The Authenticator and Supplicant need to check these bits to stop reflection attacks. It is important that message 1 contents not be used to update state, in particular the keys in use, until the data are validated with message 3.

12.7.6.2 4-way handshake message 1

Message 1 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 1 (Pairwise)

SMK Message = 0

Install = 0

Key Ack = 1

Key MIC = 0

Secure = 0

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0 – unused by this protocol version

Key Length = Cipher-suite-specific; see Table 12-4

Key Replay Counter = n – to allow Authenticator or initiator STA to match the right message 2 from Supplicant or peer STA

KeyNonce = ANonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = 0

Key Data Length = length of Key Data field in octets

Key Data = PMKID for the PMK being used during PTK generation or SMKID for SMK being used during STK generation

Processing for PTK generation is as follows:

The Authenticator sends message 1 to the Supplicant at the end of a successful IEEE 802.1X authentication, after (re)association completes for a STA that has authenticated with SAE or PSK authentication is negotiated, when a cached PMKSA is used, or after a STA requests a new key. On reception of message 1, the Supplicant determines whether the Key Replay Counter field value has been used before with the current PMKSA. If the Key Replay Counter field value is less than or equal to the current local value, the Supplicant discards the message. Otherwise, the Supplicant:

- a) Generates a new nonce SNonce.
- b) Derives PTK.
- c) Constructs message 2.

Processing for STK generation is as follows:

The initiator STA (STA_I) sends message 1 to the peer STA (STA_P) at the end of a successful SMK handshake, when SMKSA is created. On reception of message 1, the STA_P determines whether the Key Replay Counter field value has been used before with the current SMKSA. If the Key Replay Counter field value is less than or equal to the current local value, the STA_P discards the message. Otherwise, the STA_P

- a) Generates a 256-bit random number following the recommendations of 12.7.5. That number is sent as a peer nonce as part of the KeyNonce field. This Nonce is different from the peer nonce generated as part of the SMK handshake message 3.
- b) Derives STK.
- c) Constructs message 2.

12.7.6.3 4-way handshake message 2

Message 2 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0 – same as message 1

Key Type = 1 (Pairwise) – same as message 1

SMK Message = 0 – same as message 1

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 0 – same as message 1

Error = 0 – same as message 1

Request = 0 – same as message 1

Encrypted Key Data = 0

Reserved = 0 – unused by this protocol version

Key Length = 0

Key Replay Counter = n – to let the Authenticator or initiator STA know to which message 1 this corresponds

KeyNonce = SNonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC(KCK, EAPOL) – MIC computed over the body of this EAPOL-Key frame with the Key MIC field first initialized to 0

Key Data Length = length of Key Data field in octets

Key Data =

- included RSNE – the sending STA's RSNE for PTK generation or peer RSNE for the current operating band, and when this message 2 is part of a fast BSS transition initial mobility domain association or an association started through the FT protocol, the PMKR1Name calculated by the S1KH according to the procedures of 12.7.1.7.4 is included in the PMKID field of the RSNE and the FTE and MDE are also included, or;
- The sending STA's Multi-band element for PTK generation for a supported band other than the current operating band if dot11MultibandImplemented is true, or;
- The sending STA's RSNE and Multi-band element(s) for generating a single PTK for all involved bands, if dot11MultibandImplemented is true and both the Authenticator and the

- Supplicant use the same MAC address in the current operating band and the other supported band(s); or;
- The sending STA's RSNE and Multi-band element(s) for generating a different PTK for each involved band, if dot11MultibandImplemented is true and the Joint Multi-band RSNA subfield of the RSN capabilities field is 1 for both the Authenticator and the Supplicant, and either the Authenticator or the Supplicant uses different MAC addresses for different bands.
 - Lifetime of SMK and SMKID for STK generation.

Processing for PTK generation is as follows:

The Supplicant sends message 2 to the Authenticator.

On reception of message 2, the Authenticator checks that the key replay counter corresponds to the outstanding message 1. If not, it silently discards the message. Otherwise, the Authenticator:

- a) Derives PTK.
- b) Verifies the message 2 MIC.
 - 1) If the calculated MIC does not match the MIC that the Supplicant included in the EAPOL-Key frame, the Authenticator silently discards message 2.
 - 2) If the MIC is valid and this message 2 is part of a fast BSS transition initial mobility domain association or an association started through the FT protocol, the Authenticator checks that all fields of the RSNE other than the PMKID field bitwise matches the fields from the (Re)Association Request frame and that the FTE and MDE are the same as those provided in the AP's (Re)Association Response frame. If the MIC is valid and this message 2 is not part of a fast BSS transition initial mobility domain association and this message 2 is not part of an association started through the FT protocol, the Authenticator checks that the RSNE bitwise matches that from the (Re)Association Request frame.
 - i) If these are not exactly the same, the Authenticator uses MLME-DEAUTHENTICATE.request primitive to terminate the association.
 - ii) If they do match bitwise, the Authenticator constructs message 3.
- c) If management frame protection is being negotiated, the AP initializes the SA Query Transaction Identifier to an implementation-specific non-negative integer value, valid for the current pairwise security association.

Processing for STK generation is as follows:

The STA_P sends message 2 to the STA_I. On reception of message 2, the STA_I checks that the key replay counter corresponds to message 1. If not, it silently discards the message. Otherwise, the STA_I

- a) Derives the STK.
- b) Verifies the message 2 MIC using the SKCK. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the STA_I silently discards message 2.
- c) If the MIC is valid, the STA_I checks that the RSNE bitwise matches that from the SMK handshake message 5. If these are not exactly the same, STA_I silently discards the message and restarts the 4-way handshake after deleting the existing 4-way handshake states.
- d) If they do match bitwise, the STA_I checks SMKID with the value of SMKID in the SMKSA. If these are not exactly the same, STA_I silently discards the message and restarts the 4-way handshake after deleting the existing 4-way handshake states.
- e) If they do match, the STA_I constructs message 3. It also compares the Key Lifetime value from the KDE with value in its SMKSA. If value in its SMKSA is less, it discards the value received in message 2. Otherwise, it updates the value in the SMKSA with value in message 2.

12.7.6.4 4-way handshake message 3

Message 3 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0 – same as message 1

Key Type = 1 (Pairwise) – same as message 1

SMK Message = 0 - same as message 1

Install = 0/1 – For PTK generation, 0 only if the AP does not support key mapping keys, or if the STA has the No Pairwise bit (in the RSN Capabilities field) equal to 1 and only the group key is used. For STK generation, this bit is set to 1.

Key Ack = 1

Key MIC = 1

Secure = 1 (keys installed)

Error = 0 – same as message 1

Request = 0 – same as message 1

Encrypted Key Data = 1

Reserved = 0 – unused by this protocol version

Key Length = Cipher-suite-specific; see Table 12-4

Key Replay Counter = $n+1$

KeyNonce = ANonce – same as message 1

EAPOL-Key IV = 0 (Version 2) or random (Version 1)

Key RSC = For PTK generation, starting TSC or PN that the Authenticator's STA uses in MPDUs protected by GTK. For STK generation, this is set to 0.

Key MIC = MIC(KCK, EAPOL) or MIC(SKCK, EAPOL) – MIC computed over the body of this EAPOL-Key frame with the Key MIC field first initialized to 0

Key Data Length = length of Key Data field in octets of included RSNEs and GTK

Key Data =

- For PTK generation for the current operating band, the AP's Beacon/Probe Response frame's RSNE for the current operating band, and, optionally, a second RSNE that is the Authenticator's pairwise cipher suite assignment for the current operating band, and, if a group cipher has been negotiated, the GTK and the GTK's key identifier (see 12.7.2) for the current operating band, and if management frame protection is negotiated, the IGTK KDE, and when this message 3 is part of a fast BSS transition initial mobility domain association or an association started through the FT protocol, the PMKR1Name calculated according to the procedures of 12.7.1.7.4 in the PMKID field of the RSNE and the FTE with the same contents as in the (Re)Association Response frame, the MDE with the same contents as in the (Re)Association Response frame, the reassociation deadline timeout set to the minimum of dot11FTReassociationDeadline and the key lifetime in the TIE[ReassociationDeadline], and the PTK lifetime in the TIE[KeyLifetime]; or
- For PTK generation for a supported band other than the current operating band, the Authenticator's Beacon/DMG Beacon/Announce/Probe Response/Information Response frame's Multi-band element associated with the supported band, and optionally a second Multi-band element that indicates the Authenticator's pairwise cipher suite assignment for the supported band, and, if group cipher for the supported band is negotiated, the Multi-band GTK KDE for the supported band if dot11MultibandImplemented is true, or;

- For generating a single PTK for all involved bands, the Authenticator's Beacon/DMG Beacon/Announce/Probe Response/Information Response frame's RSNE and Multi-band element(s), and optionally, additional RSNE and Multi-band element(s) that indicate the Authenticator's assignment of one pairwise cipher suite for all involved bands; if a group cipher for all involved bands is negotiated, the GTK and the GTK's key identifier for all involved bands, if dot11MultibandImplemented is true and both the Authenticator and the Supplicant use the same MAC address in the current operating band and the other supported band(s), or;
- For generating different PTKs for the current operating band and other supported band(s), the Authenticator's Beacon/DMG Beacon/Announce/Probe Response/Information Response frame's RSNE and Multi-band element(s), and optionally, additional RSNE and Multi-band elements that are the Authenticator's pairwise cipher suite assignments for one or more involved bands; if group ciphers for the involved bands are negotiated, the Multi-band GTK KDEs for the involved bands, if dot11MultibandImplemented is true and the Joint Multi-band RSNA subfield is 1 for both the Authenticator and Supplicant, and either the Authenticator or the Supplicant uses different MAC addresses for different bands.
- For STK generation Initiator RSNE, Lifetime of SMK is used.
- If the Extended Key ID for Individually Addressed Frames subfield of the RSN Capabilities field is 1 for both the Authenticator/STA_I and Supplicant/STA_P, then the Authenticator/STA_I includes the Key ID KDE with the assigned key identifier for the current operating band; or the Authenticator includes the Multi-band Key ID KDE(s) with the assigned key identifier(s) for one or more supported bands if dot11MultibandImplemented is true.

Processing for PTK generation is as follows:

If the Extended Key ID for Individually Addressed Frames subfield of the RSN Capabilities field is 1 for both the Authenticator and the Supplicant, then the Authenticator assigns a new Key ID for the PTKSA in the range 0 to 1 that is different from the Key ID assigned in the previous handshake and uses the MLME-SETKEYS.request primitive to install the new key to receive individually addressed MPDUs protected by the PTK with the assigned Key ID. Otherwise Key ID 0 is used and installation of the key is deferred until after message 4 has been received. The Authenticator sends message 3 to the Supplicant.

NOTE—If an existing PTK is still in effect, the Authenticator IEEE 802.11 MAC continues to transmit protected, individually addressed MPDUs (if any) using the existing key. With the installation of the new key for receive, the Authenticator is able to receive protected, individually addressed MPDUs using either the old key (if present) or the new key.

On reception of message 3, the Supplicant silently discards the message if the Key Replay Counter field value has already been used or if the ANonce value in message 3 differs from the ANonce value in message 1. The Supplicant also:

- a) Verifies the RSNE. If this message 3 is part of a fast BSS transition initial mobility domain association or an association started through the FT protocol, the Supplicant verifies that the PMKR1Name in the PMKID field of the RSNE is identical to the value it sent in message 2 and verifies that all other fields of the RSNE are identical to the fields in the RSNE present in the Beacon or Probe Response frames and verifies that the FTE and MDE are the same as in the (Re)Association Response frame. Otherwise, the Supplicant verifies that the RSNE is identical to that the STA received in the Beacon or Probe Response frame. If any of these verification steps indicates a mismatch, the STA shall disassociate or deauthenticate. If a second RSNE is provided in the message, the Supplicant uses the pairwise cipher suite specified in the second RSNE or deauthenticates.
- b) Verifies the message 3 MIC. If the calculated MIC does not match the MIC that the Authenticator included in the EAPOL-Key frame, the Supplicant silently discards message 3.

- c) Updates the last-seen value of the Key Replay Counter field.
- d) If the Extended Key ID for Individually Addressed Frames subfield of the RSN Capabilities field is 1 for both the Authenticator and Supplicant: Uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to receive individually addressed MPDUs protected by the PTK with the assigned Key ID.
- e) Constructs message 4.
- f) Sends message 4 to the Authenticator.
- g) Uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to send and, if the receive key has not yet been installed, to receive individually addressed MPDUs protected by the PTK. The GTK is also configured by MLME-SETKEYS primitive.

Processing for STK generation is as follows:

If the Extended Key ID for Individually Addressed Frames subfield of the RSN Capabilities field is set to 1 for both the STA_I and the STA_P, then the Authenticator assigns a new Key ID for the STKSA in the range 0 to 1 that is different from the Key ID assigned in the previous handshake and uses the MLME-SETKEYS.request primitive to install the new key to receive individually addressed MPDUs protected by the STK with the assigned Key ID. Otherwise Key ID 0 is used and installation of the key is deferred until after message 4 has been received. The STA_I sends message 3 to the STA_P.

NOTE—If an existing STK is still in effect, the STA_I IEEE 802.11 MAC continues to transmit protected, individually addressed MPDUs (if any) using the existing key. With the installation of the new key for receive, the STA_I is able to receive protected, individually addressed MPDUs using both the old key (if present) or the new key.

On reception of message 3, the STA_P silently discards the message if the Key Replay Counter field value has already been used or if the INonce value in message 3 differs from the INonce value in message 1. Otherwise,

- a) The STA_P verifies the message 3 MIC using the SKCK in the SMKSA. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the STA_I silently discards message 3.
- b) If the MIC is valid, the STA_P checks that the RSNE bitwise matches that from the 4-way handshake message 2. If these are not exactly the same, STA_P silently discards the message and deletes existing 4-way handshake states.
- c) If they do match, the STA_P constructs message 4. It also compares the Key Lifetime value from KDE with value in its SMKSA. If value in the SMKSA is less, it discards the value received in message 3. Otherwise, it updates the value in the SMKSA with value in message 3.
- d) If the Extended Key ID for Individually Addressed Frames subfield of the RSN Capabilities field is 1 for both the Authenticator and Supplicant then prior to sending message 4, STA_P uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to receive individually addressed MPDUs protected by the STK with the assigned Key ID.
- e) After sending message 4, STA_P uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to send and, if the receive key has not yet been installed, to receive individually addressed MPDUs protected by the STK with the assigned Key ID.

12.7.6.5 4-way handshake message 4

Message 4 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0 – same as message 1

Key Type = 1 (Pairwise) – same as message 1
SMK Message = 0 - same as message 1
Install = 0
Key Ack = 0 – this is the last message
Key MIC = 1
Secure = 1
Error = 0
Request = 0
Encrypted Key Data = 0
Reserved = 0 – unused by this protocol version
Key Length = 0
Key Replay Counter = $n+1$
KeyNonce = 0
EAPOL-Key IV = 0
Key RSC = 0
Key MIC = MIC(KCK, EAPOL) or MIC(SKCK, EAPOL) – MIC computed over the body of this EAPOL-Key frame with the Key MIC field first initialized to 0
Key Data Length = length of Key Data field in octets
Key Data = none required

Processing for PTK generation is as follows:

The Supplicant sends message 4 to the Authenticator. Note that when the 4-way handshake is first used, message 4 is sent in the clear.

On reception of message 4, the Authenticator verifies that the Key Replay Counter field value is one that it used on this 4-way handshake; if it is not, it silently discards the message. Otherwise:

- a) The Authenticator checks the MIC. If the calculated MIC does not match the MIC that the Supplicant included in the EAPOL-Key frame, the Authenticator silently discards message 4.
- b) If the MIC is valid, the Authenticator uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to send and, if the receive key has not yet been installed, to receive protected, individually addressed MPDUs using for the new PTK.
- c) The Authenticator updates the Key Replay Counter field so that it uses a fresh value if a rekey becomes necessary.

Processing for STK generation is as follows:

The STA_P sends message 4 to the STA_I. On reception of message 4, the STA_I verifies that the Key Replay Counter field value is one that it used on this 4-way handshake; if it is not, it silently discards the message. Otherwise,

- a) The STA_I checks the MIC. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the STA_I silently discards message 4.
- b) If the MIC is valid, the STA_I uses the MLME-SETKEYS.request primitive to configure the IEEE 802.11 MAC to send and, if the receive key has not yet been installed, to receive protected, individually addressed MPDUs using for the new STK.
- c) The STA_I updates the Key Replay Counter field so that it uses a fresh value if a rekey becomes necessary.

12.7.6.6 4-way handshake implementation considerations

When the 4-way handshake is used as part of the STK handshake, the initiator STA acts as Authenticator and peer STA acts as Supplicant.

If the Authenticator does not receive a reply to its messages, it shall attempt dot11RSNAConfigPairwiseUpdateCount transmits of the message, plus a final timeout. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval or the listen interval is zero, then 100 ms shall be used for all timeout values. If it still has not received a response after these retries, then for PTK generation the Authenticator should deauthenticate the STA, and for STK generation the STAs should delete the SMKSA and initiate an STSL application teardown procedure.

For PTK generation, if the STA does not receive message 1 within the expected time interval (prior to IEEE 802.1X timeout), it should disassociate, deauthenticate, and try another AP/STA. For STK generation, if the peer STA does not receive message 1 or message 3 within the expected time interval (prior to dot11RSNAConfigSATimeout as specified in 12.7.8), it deletes the SMKSA and invokes an STSL application teardown procedure.

The Authenticator should ignore EAPOL-Key frames it is not expecting in reply to messages it has sent or EAPOL-Key frames in which the Ack bit is 1. This stops an attacker from sending the first message to the Supplicant who responds to the Authenticator.

An implementation should save the KCK and KEK beyond the 4-way handshake, as they are needed for group key handshakes, STK Rekeying, and recovery from TKIP MIC failures.

The Supplicant uses the MLME-SETKEYS.request primitive to configure the temporal key from 12.7.1 into its STA after sending message 4 to the Authenticator.

If the RSNE check for message 2 or message 3 fails, the SME should log an error and deauthenticate the peer.

12.7.6.7 Sample 4-way handshake

The following is an informative sample of a 4-way handshake for illustration.

After IEEE 802.1X authentication completes by the AP sending an EAP-Success, the AP initiates the 4-way handshake. See Figure 12-46.

The 4-way handshake consists of the following steps:

- a) The Authenticator sends an EAPOL-Key frame containing an ANonce.
- b) The Supplicant derives a PTK from ANonce and SNonce.
- c) The Supplicant sends an EAPOL-Key frame containing SNonce, the RSNE from the (Re)Association Request frame, and a MIC.
- d) The Authenticator derives PTK from ANonce and SNonce and validates the MIC in the EAPOL-Key frame.
- e) The Authenticator sends an EAPOL-Key frame containing ANonce, the RSNE from its Beacon or Probe Response frames, the MIC, the GTK, an indication of whether to install the temporal keys, and if management frame protection is negotiated, the IGTK.
- f) The Supplicant sends an EAPOL-Key frame to confirm whether the temporal keys were installed.

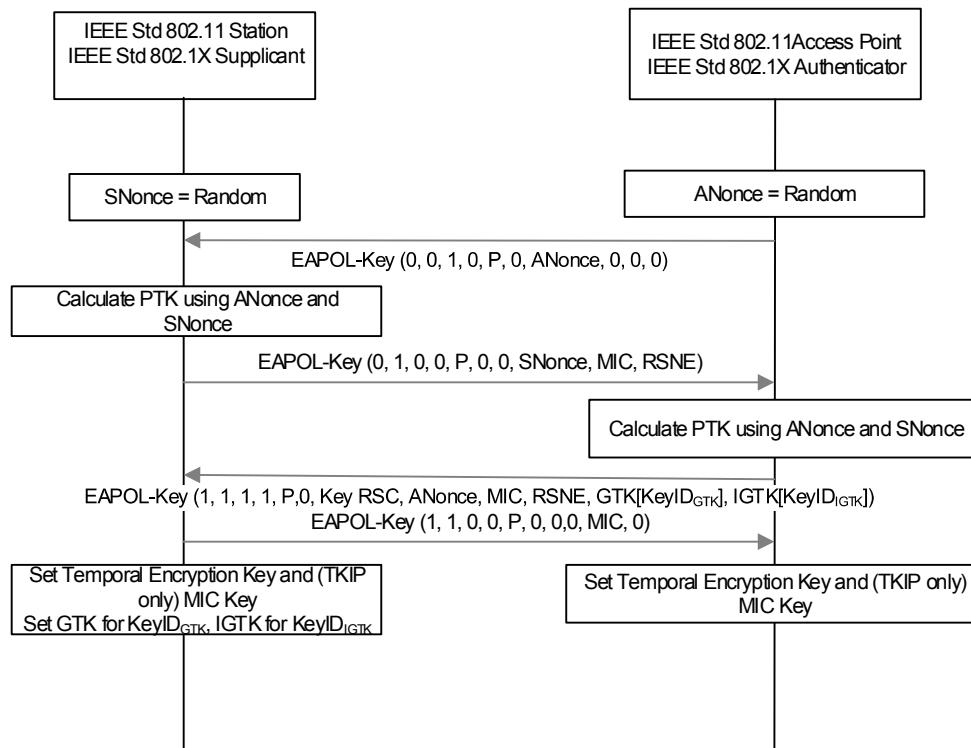

Figure 12-46—Sample 4-way handshake

12.7.6.8 4-way handshake analysis

The following is an informative analysis of the 4-way handshake.

This subclause makes the trust assumptions used in this protocol explicit. The protocol assumes the following:

- The PMK is known only by the Supplicant’s STA and the Authenticator’s STA.
- The Supplicant’s STA uses IEEE 802 address SPA.
- The Authenticator’s STA uses IEEE 802 address AA.

In many instantiations the RSNA architecture immediately breaks the first assumption because the IEEE 802.1X AS also knows the PMK. Therefore, additional assumptions are required:

- The AS does not expose the PMK to other parties.
- The AS does not masquerade as the Supplicant to the Authenticator.
- The AS does not masquerade as the Authenticator to the Supplicant.
- The AS does not masquerade as the Supplicant’s STA.
- The AS does not masquerade as the Authenticator’s STA.

The protocol also assumes this particular Supplicant-Authenticator pair is authorized to know this PMK and to use it in the 4-way handshake. If any of these assumptions are broken, then the protocol fails to provide any security guarantees.

The protocol also assumes that the AS delivers the correct PMK to the AP with IEEE 802 address AA and that the STA with IEEE 802 address SPA hosts the Supplicant that negotiated the PMK with the AS. None

of the protocols defined by this standard and IEEE Std 802.1X-2010 permit the AS, the Authenticator, the Supplicant, or either STA to verify these assumptions.

The PTK derivation step

$$\text{PTK} = \text{PRF-Length}(\text{PMK}, \text{"Pairwise key expansion"}, \text{Min(AA,SPA)} \parallel \text{Max(AA,SPA)} \parallel \\ \text{Min(ANonce,SNonce)} \parallel \text{Max(ANonce,SNonce)})$$

performs a number of functions:

- Including the AA and SPA in the computation
- Binds the PTK to the communicating STAs and
- Prevents undetected man-in-the-middle attacks against 4-way handshake messages between the STAs with these two IEEE 802 addresses.
- If ANonce is randomly selected, including ANonce
 - Guarantees the STA at IEEE 802 address AA that PTK is fresh,
 - Guarantees that message 2 and message 4 are live, and
 - Uniquely identifies PTK as <AA, ANonce>.
- If SNonce is randomly selected, including SNonce
 - Guarantees the STA at IEEE 802 address SPA that PTK is fresh,
 - Guarantees that message 3 is live, and
 - Uniquely identifies PTK as <SPA, SNonce>.

Choosing the nonces randomly helps prevent precomputation attacks. With unpredictable nonces, a man-in-the-middle attack that uses the Supplicant to precompute messages to attack the Authenticator cannot progress beyond message 2, and a similar attack against the Supplicant cannot progress beyond message 3. The protocol might execute further before an error if predictable nonces are used.

Message 1 delivers ANonce to the Supplicant and initiates negotiation for a new PTK. It identifies AA as the peer STA to the Supplicant's STA. If an adversary modifies either of the addresses or ANonce, the Authenticator detects the result when validating the MIC in message 2. Message 1 does not carry a MIC, as it is impossible for the Supplicant to distinguish this message from a replay without maintaining state of all security associations through all time (PMK might be a static key).

Message 2 delivers SNonce to the Authenticator so it can derive the PTK. If the Authenticator selected ANonce randomly, message 2 also demonstrates to the Authenticator that the Supplicant is live, that the PTK is fresh, and that there is no man-in-the-middle attack, as the PTK includes the IEEE 802 MAC addresses of both. Inclusion of ANonce in the PTK derivation also protects against replay. The MIC prevents undetected modification of message 2 contents.

Message 3 confirms to the Supplicant that there is no man-in-the-middle attack. If the Supplicant selected SNonce randomly, it also demonstrates that the PTK is fresh and that the Authenticator is live. The MIC again prevents undetected modification of message 3.

While message 4 serves no cryptographic purpose, it serves as an acknowledgment to message 3. It is required to inform the Authenticator that the Supplicant has installed the PTK and GTK and hence can receive encrypted frames.

The PTK and GTK are installed by using MLME-SETKEYS.request primitive after message 4 is sent. The PTK is installed before the GTK.

Then the 4-way handshake uses a correct, but unusual, mechanism to guard against replay. As noted earlier in this subclause, ANonce provides replay protection to the Authenticator, and SNonce to the Supplicant. In most session initiation protocols, replay protection is accomplished explicitly by selecting a nonce randomly and requiring the peer to reflect the received nonce in a response message. The 4-way handshake instead mixes ANonce and SNonce into the PTK, and replays are detected implicitly by MIC failures. In particular, the Key Replay Counter field serves no cryptographic purpose in the 4-way handshake. Its presence is not detrimental, however, and it plays a useful role as a minor performance optimization for processing stale instances of message 2. This replay mechanism is correct, but its implicit nature makes the protocol harder to understand than an explicit approach.

It is critical to the correctness of the 4-way handshake that at least one bit differs in each message. Within the 4-way handshake, message 1 can be recognized as the only one in which the Key MIC bit is 0, meaning message 1 does not include the MIC, while message 2 to message 4 do. Message 3 differs from message 2 by not asserting the Ack bit and from message 4 by asserting the Ack Bit. Message 2 differs from message 4 by including the RSNE.

Request messages are distinct from 4-way handshake messages because the former asserts the Request bit and 4-way handshake messages do not. Group key handshake messages are distinct from 4-way handshake messages because they assert a different key type.

12.7.7 Group key handshake

12.7.7.1 General

The Authenticator uses the Group key handshake to send a new GTK and, if management frame protection is negotiated, a new IGTK to the Supplicant.

The Authenticator may initiate the exchange when a Supplicant is disassociated or deauthenticated.

Message 1: Authenticator → Supplicant:

EAPOL-Key(1,1,1,0,G,0,Key RSC,0, MIC, GTK[N],IGTK[M])

Message 2: Supplicant → Authenticator: EAPOL-Key(1,1,0,0,G,0,0,0,MIC,0)

Here, the following assumptions apply:

- Key RSC denotes the last TSC or PN sent using the GTK.
- GTK[N] denotes the GTK with its key identifier as defined in 12.7.2 using the KEK defined in 12.7.1.3 and associated IV.
- IGTK[M], when present, denotes the IGTK with its key identifier as defined in 12.7.2 using the KEK defined in 12.7.1.3 and associated IV.
- The MIC is computed over the body of the EAPOL-Key frame (with the MIC field zeroed for the computation) using the KCK defined in 12.7.1.3.

The Supplicant may trigger a group key handshake by sending an EAPOL-Key frame with the Request bit set to 1 and the type of the Group Key bit.

An Authenticator shall do a 4-way handshake before a group key handshake if both are required to be done.

NOTE—The Authenticator cannot initiate the group key handshake until the 4-way handshake completes successfully.

12.7.7.2 Group key handshake message 1

Message 1 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 0

Install = 0

Key Ack = 1

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 1

Reserved = 0

Key Length = 0

Key Replay Counter = $n+2$

KeyNonce = 0

EAPOL-Key IV = 0 (Version 2) or random (Version 1)

Key RSC = last TSC or PN for the GTK

Key MIC = MIC(KCK, EAPOL)

Key Data Length = Cipher-suite-specific; see Table 12-4

Key Data = encrypted, encapsulated

— GTK and the GTK's key identifier (see 12.7.2)

— When present, IGTK, IGTK's key identifier, and IPN (see 12.7.2)

The Authenticator sends message 1 to the Supplicant.

On reception of message 1, the Supplicant:

- a) Verifies that the Key Replay Counter field value has not yet been seen before, i.e., its value is strictly larger than that in any other EAPOL-Key frame received thus far during this session.
- b) Verifies that the MIC is valid, i.e., it uses the KCK that is part of the PTK to verify that there is no data integrity error.
- c) Uses the MLME-SETKEYS.request primitive to configure the temporal GTK and, when present, IGTK into its IEEE 802.11 MAC.
- d) Responds by creating and sending message 2 of the group key handshake to the Authenticator and incrementing the replay counter.

NOTE—The Authenticator increments and uses a new Key Replay Counter field value on every message 1 instance, even retries, because the message 2 responding to an earlier message 1 might have been lost. If the Authenticator did not increment the replay counter, the Supplicant discards the retry, and no responding message 2 ever arrives.

12.7.7.3 Group key handshake message 2

Message 2 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0 – same as message 1

Key Type = 0 (Group/SMK) – same as message 1

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = $n+2$ – same as message 1

KeyNonce = 0

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC(KCK, EAPOL)

Key Data Length = 0

Key Data = none required

On reception of message 2, the Authenticator:

- Verifies that the Key Replay Counter field value matches one it has used in the group key handshake.
- Verifies that the MIC is valid, i.e., it uses the KCK that is part of the PTK to verify that there is no data integrity error.

12.7.7.4 Group key handshake implementation considerations

If the Authenticator does not receive a reply to its messages, its shall attempt dot11RSNAConfigGroupUpdateCount transmits of the message, plus a final timeout. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval or the listen interval is zero, then 100 ms shall be used for all timeout values. If it still has not received a response after this, then the Authenticator's STA should use the MLME-DEAUTHENTICATE.request primitive to deauthenticate the STA.

12.7.7.5 Sample group key handshake

The following is an informative sample of a group key handshake for illustration.

The state machines in 12.7.10 and 12.7.11 change the GTK and, when present, IGTK in use by the network. See Figure 12-47.

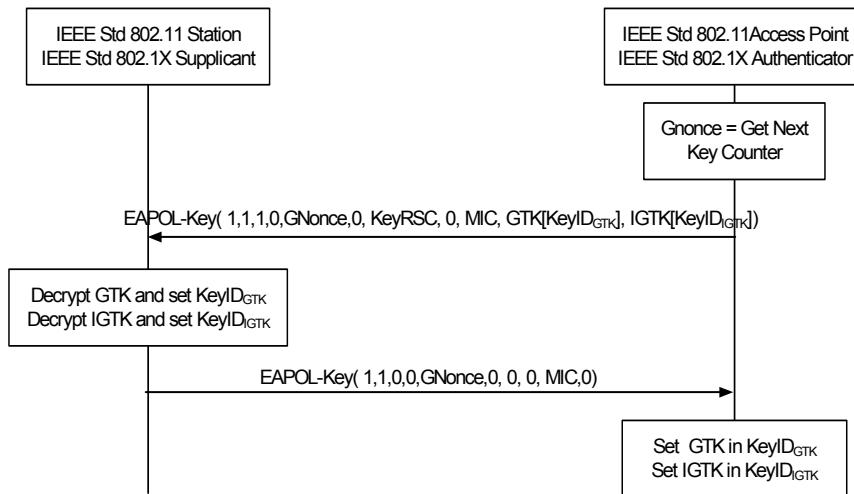

Figure 12-47—Sample group key handshake

The following steps occur:

- The Authenticator generates a new GTK and when management frame protection has been negotiated, a new IGTK. It encapsulates the GTK and, as necessary, the IGTK, and sends an EAPOL-Key frame containing the GTK and IGTK (message 1), along with the last TSC or PN used with the GTK (RSC) and the last IPN used with the IGTK.
- On receiving the EAPOL-Key frame, the Supplicant validates the MIC, decapsulates the GTK and, when present, the IGTK, and uses the MLME-SETKEYS.request primitive to configure the GTK, PN, IGTK, RSC, and IPN in its STA.
- The Supplicant then constructs and sends an EAPOL-Key frame in acknowledgment to the Authenticator.
- On receiving the EAPOL-Key frame, the Authenticator validates the MIC. If the GTK and, if present, the IGTK are not already configured into IEEE 802.11 MAC, after the Authenticator has delivered the GTK and IGTK to all associated STAs, it uses the MLME-SETKEYS.request primitive to configure the GTK and IGTK.

12.7.8 PeerKey handshake

12.7.8.1 General

The PeerKey handshake occurs after any other STSL setup procedures and is used to create an STKSA providing data confidentiality between the two STAs. The AP establishes an RSNA with each STA prior to PeerKey setup. The initiator STA starts the PeerKey handshake, at the conclusion of which a key is established to secure the connection.

STSL security PeerKey handshake is used to establish security for Data frames passed directly between two STAs associated with the same AP. The AP establishes an RSNA with each STA prior to the PeerKey handshake. After the STAs establish the STSL, the initiator STA starts the PeerKey handshake, at the conclusion of which a key is established to secure the connection. The PeerKey handshake is used to create an STKSA between the two STAs.

The PeerKey EAPOL-Key exchange provides a mechanism for obtaining the keys to be used for direct station-to-station communication. The initiator STA shall start a timer when it sends the first EAPOL-Key

frame, and the peer STA shall do the same on receipt of the first EAPOL-Key frame. On expiration of this timer, the STA shall transition to the STKINIT state.

A STA should use the PeerKey handshake prior to transferring any direct station-to-station Data frames. The STKSA should be deleted when the station-to-station connection is terminated.

Here, the following assumptions apply:

- EAPOL-Key() denotes an EAPOL-Key frame conveying the specified argument list, using the notation introduced in 12.7.4.
- STA_I is the initiator STA.
- STA_P is the peer STA.
- AP is the access point with which both the STA_I and the STA_P are associated.
- MAC_I is the MAC address of the STA_I.
- MAC_P is the MAC address of the STA_I.
- INonce is the nonce generated by the STA_I.
- PNonce is the nonce generated by the STA_P.

The PeerKey handshake has two components:

- a) **SMK handshake:** This handshake is initiated by the initiator STA, and as a result of this handshake, the SMKSA is installed in both the STAs. This message exchange goes through the AP and is protected using the PTK.
- b) **4-way STK handshake:** Using the installed SMKSA, the initiator STA initiates the 4-way handshake (per 12.7.6), and as a result of this, the STKSA gets installed in both the STAs. The STKSA is used for securing data exchange between the initiator STA and the peer STA. The 4-way handshake analysis described in 12.7.6.8 applies to the 4-way STK handshake.

12.7.8.2 SMK handshake

12.7.8.2.1 General

The initiator STA initiates the SMK handshake by sending the first message to the AP to establish an SMKSA between itself and another STA associated with the same AP. Unlike the 4-way handshake and the group key handshake, the SMK handshake is initiated by the initiator STA.

- Message 1: Initiator STA → AP: EAPOL-Key(1,1,0,0,0,1,0, INonce, MIC, RSNE_I, MAC_P KDE)
- Message 2: AP → Peer STA: EAPOL-Key(1,1,1,0,0,1,0, INonce, MIC, RSNE_I, MAC_I KDE)
- Message 3: Peer STA → AP: EAPOL-Key(1,1,0,0,0,1,0, PNonce, MIC, RSNE_P, MAC_I KDE, Initiator Nonce KDE)
- Message 4: AP → Peer STA: EAPOL-Key(1,1,0,1,0,1,0, PNonce, MIC, MAC_I KDE, Initiator Nonce KDE, SMK KDE, Lifetime KDE)
- Message 5: AP → Initiator STA: EAPOL-Key(1,1,0,0,0,1,0, INonce, MIC, RSNE_P, MAC_P KDE, Peer Nonce KDE, SMK KDE, Lifetime KDE)

12.7.8.2.2 SMK handshake message 1

The initiator STA creates the RSNE (see 9.4.2.25) by including the Element ID, length, version, and pairwise cipher suite list fields. Since the group cipher suit field is before the pairwise cipher suite list field (so the STA needs to include it), the STA includes any value in this field, and the receiving STA ignores it. The initiator STA also generates a 256-bit random number following the recommendations of 12.7.5. That number is sent in the Key Nonce field.

Message 1 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 1

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter of initiating STA

KeyNonce = INonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (initiating STA's KCK, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Initiator RSNE, peer MAC address KDE

The STA_I sends message 1 to the AP.

On receipt of message 1, the AP checks that the key replay counter corresponds to message 1. If not, it silently discards the message. Otherwise:

- a) The AP verifies the message 1 MIC using the STA_I PTKSA. If the calculated MIC does not match the MIC that the STA_I included in the EAPOL-Key frame, the AP silently discards message 1.
- b) If the MIC is correct, the AP checks if the STA_P is reachable. If it is not reachable, the AP shall send an error EAPOL-Key frame to STA_I per 12.7.8.5.2. After sending the message, AP silently discards message 1.
- c) The AP checks if the AP has a secure connection with STA_P. If not, the AP shall send an error EAPOL-Key frame to STA_I per 12.7.8.5.3. After sending the message, AP silently discards message 1.
- d) If all checks succeed, the AP creates message 2 using the STA_P PTKSA. The AP copies the contents of message 1 to create message 2.

12.7.8.2.3 SMK handshake message 2

Message 2 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 1

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter of AP and STA_P

KeyNonce = INonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of the STA_P, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Initiator RSNE, initiator MAC address KDE

The AP sends message 2 to the STA_P. On receipt of message 2, the STA_P checks that the key replay counter corresponds to message 2. If not, it silently discards the message. Otherwise,

- a) The STA_P verifies the message 2 MIC using the STA_P PTKSA. If the calculated MIC does not match the MIC that the AP included in the EAPOL-Key frame, the STA_P silently discards message 2.
- b) If the MIC is correct, the STA_P checks if it supports at least one cipher suites proposed by the STA_I. If it does not, the STA_P shall send an error EAPOL-Key frame to STA_I through the AP per 12.7.8.5.4. After sending the error message, the STA_P silently discards message 2.
- c) STA_O checks if it has already created an STSL with STA_I. If it has not, STA_P shall send an error EAPOL-Key frame to STA_I through the AP per 12.7.8.5.5. After sending the error message, the STA_P silently discards message 2.
- d) If all checks succeed, the STA_P creates the state of PeerKey handshake and stores the INonce and the RSNE received in message 2.
- e) STA_P selects a support cipher suite from the cipher suite list proposed by the STA_I and creates the peer RSNE, which is sent with message 3.
- f) STA_P generates a 256-bit random number following the recommendations of 12.7.5. That number is sent as the peer Nonce KDE with message 3.
- g) Using all the information, STA_P creates message 3.

12.7.8.2.4 SMK handshake message 3

Message 3 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter of peer STA

KeyNonce = PNonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of STA_I, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Peer RSNE, initiator MAC address KDE, initiator Nonce KDE

The STA_P sends message 3 to the AP. On receipt of message 3, the AP checks that the key replay counter corresponds to message 3. If not, it silently discards the message. Otherwise,

- a) The AP verifies the message 1 MIC using the STA_I PTKSA. If the calculated MIC does not match the MIC that the STA_P included in the EAPOL-Key frame, the AP silently discards message 1.
- b) If MIC is correct, the AP checks if the STA_I is reachable. If it is not reachable, the AP shall send an error EAPOL-Key frame to the STA_P per 12.7.8.5.2. After sending the message, the AP silently discards message 3.
- c) The AP checks if the AP has secure connection with STA_I. If it does not, the AP shall send an error EAPOL-Key frame to STA_P per 12.7.8.5.3. After sending the message, the AP silently discards message 3.
- d) If all checks succeed, the AP generates a 256-bit random number drawn from a uniform distribution that is used as the SMK, which is sent with message 4 and message 5 as SMK KDEs.
- e) Depending on the strength of random number generator, the AP sets the lifetime of the SMK, which is sent with message 4 and message 5 as Lifetime KDEs.
- f) Using all the information, the AP creates message 4 and message 5.

12.7.8.2.5 SMK handshake message 4

Message 4 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 1

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 1

Reserved = 0

Key Length = Cipher-suite-specific; see Table 12-4

Key Replay Counter = request EAPOL replay counter of AP

KeyNonce = PNonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of the STA_I, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Encrypted initiator MAC address KDE, Initiator Nonce KDE, SMK KDE (contains SMK and PNonce), Lifetime KDE

The AP sends message 4 to the STA_P. On receipt of message 4, the STA_P checks that the key replay counter corresponds to message 4. If it does not, STA_P silently discards the message. Otherwise,

- a) The STA_P verifies the message 4 MIC using STA_P PTKSA. If the calculated MIC does not match the MIC that the AP included in the EAPOL-Key frame, the STA_P silently discards message 4.
- b) If the MIC is correct, STA_P identifies the PeerKey session using the PNonce sent as part of the Key Nonce field of message 4. If STA_P has an existing PeerKey state for this session, i.e., STA_P has received message 2 and this message is a follow-up to that. If STA_P has an existing PeerKey state for this session, STA_P silently discards message 4.
- c) If all checks succeed, STA_P decrypts the Key Data field of message 4 and extracts the MAC_I, the INonce, the PNonce, the SMK, and the lifetime from message 4. The STA_P verifies the extracted INonce against the INonce originally received as part of message 2.
- d) The STA_P calculates the SMKID per 12.7.1.6.
- e) The STA_P checks the value of the lifetime with the maximum value it can support. If the lifetime suggested by the AP is too long, the STA_P selects a lower value that it can support.
- f) Using all the information, the STA_P creates the SMKSA for this PeerKey session.

12.7.8.2.6 SMK handshake message 5

Message 5 uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 0

Encrypted Key Data = 1

Reserved = 0

Key Length = Cipher-suite-specific; see Table 12-4

Key Replay Counter = request EAPOL replay counter of AP

KeyNonce = INonce

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC (KCK of the STA_I, EAPOL)

Key Data Length = Length of Key Data field in octets

Key Data = Encrypted peer RSNE, peer MAC address KDE, peer Nonce KDE, SMK KDE (contains SMK and INonce), Lifetime KDE

The AP sends message 5 to the STA_I. On receipt of message 5, the STA_I checks that the key replay counter corresponds to message 5. If it does not, the STA_I silently discards the message. Otherwise,

- a) STA_I verifies the message 4 MIC using STA_P PTKSA. If the calculated MIC does not match the MIC that the AP included in the EAPOL-Key frame, the STA_I silently discards message 5.
- b) If the MIC is correct, the STA_I identifies the PeerKey session using the INonce sent as part of the Key Nonce field of message 5. If STA_I has an existing PeerKey state for this session, i.e., STA_I has initiated this message exchange using message 1 and this message is a follow-up to that. If STA_I has an existing PeerKey state for this session, STA_I shall silently discard message 5.
- c) If all checks succeed, STA_I decrypts the Key Data field of message 5 and extracts the peer RSNE, the MAC_P, the INonce, the PNonce, the SMK, and the lifetime from message 5.
- d) The STA_I verifies that the peer RSNE includes a valid cipher (i.e., one that was included in an initiator RSNE). If not, STA_I discards the message and sends an Error KDE ERR_CPHR_NS.
- e) The STA_I calculates SMKID per 12.7.1.6.
- f) The STA_I checks the value of the lifetime with the maximum value it can support. If the lifetime suggested by the AP is too long, STA_I selects a lower value that can support.
- g) Using all the information, the STA_I creates the SMKSA for this PeerKey session.

12.7.8.3 PeerKey setup and handshake error conditions

If the STA_P does not receive a valid SMK message 2 or a 4-way STK message 1 after sending the EAPOL-Key request frame to initiate the PeerKey rekey within a 200 ms timeout, the STA_P shall invoke an STSL application teardown procedure.

If the STA_I does not receive an SMK message 5 from the AP, the STA_I shall attempt dot11RSNAConfigSMKUpdateCount transmits of the SMK handshake message 1 plus a final timeout. If the STA_I still has not received a response after these retries, it shall invoke an STSL application teardown procedure. The retransmit timeout value shall be 200 ms for the first timeout, the listen interval for the second timeout, and twice the listen interval for subsequent timeouts. If there is no listen interval or the listen interval is zero, then 200 ms shall be used for all timeout values.

There is no specific recovery mechanism at the AP if the SMK message 3 is dropped. This results in a timeout by the STA_I after nonreceipt of SMK message 5, as described in the preceding paragraph.

If the SMK message 4 is not received by the STA_P, a failure is detected during the 4-way STK handshake. In this case, the STA_P discards the EAPOL-Key frames without the proper key. This failure is covered by behavior described in 12.7.6.6 and results in teardown of the STSL.

Upon receipt of the SMK message 5, the STA_I transmits message 1 of the 4-way STK handshake to the STA_P. If the STA_I does not receive message 2 of the 4-way STK handshake from the STA_P, it shall attempt dot11RSNAConfigSMKUpdateCount transmits of 4-way STK handshake message 1, plus a final timeout. If STA_I still has not received a response after these retries, it shall invoke an STSL application teardown procedure. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval or the listen interval is zero, then 100 ms shall be used for all timeout values.

There is no specific recovery mechanism at the STA_P if the SMK message 3 is lost. This results in a timeout on the STA_I, as described in the preceding paragraph, and a subsequent reinitiation of the SMK handshake. The STA_P shall allow reinitiation of the SMK handshake at any point prior to receipt of SMK message 4.

12.7.8.4 STKSA rekeying

Rekeying is always initiated by the STA_I. When needed, the STA_P sends an EAPOL-Key request frame to the STA_I to request rekeying. The STA_P shall wait a minimum of one half the IEEE 802.1X timeout after the STSL setup before initiating a PeerKey rekey procedure. To perform rekeying, there are two cases:

- If SMK timer has not expired, the STAs initiate a 4-way handshake to create a new STK. The 4-way handshake is always initiated by the STA_I. In this case, the STA_P should not delete any existing STKSA prior to verifying message 3 of the 4-way handshake with STA_I for this session.
- If the SMK has expired, the STA_I shall not use an existing STKSA and shall start the SMK handshake followed by a 4-way handshake to create new keys.

The format of the EAPOL-Key request frame in case a) from STA_P to STA_I is as follows:

Request message: STA_P → STA_I: EAPOL-Key(1,1,0,0,1,0,0,0, MIC, PMKID KDE)

The request message uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 1 (PTK)

SMK Message = 0

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 0

Request = 1

Encrypted Key Data = 0

Reserved = 0
Key Length = 0
Key Replay Counter = request replay counter of peer STA
KeyNonce = 0
EAPOL-Key IV = 0
Key RSC = 0
Key MIC = MIC computed over the body of this EAPOL-Key frame
Key Data Length = Length of Key Data field in octets
Key Data = SMKID in SMKID KDE

12.7.8.5 Error reporting

12.7.8.5.1 General

Error reporting messages are defined in this subclause and used to report errors whenever STAs or an AP detect an error during the SMK handshake.

The AP, upon receiving the error messages defined in this subclause or upon generating the error messages defined in this subclause, should log the error. The STA, upon receipt of the error messages defined in this subclause, shall tear down the STSL with the other STA and clear all of the PeerKey states.

The format of EAPOL-Key request frame for reporting an error message is as follows:

Error message: EAPOL-Key(1,1,0,0,0,1,0, 0, MIC, Error KDE, MAC Address KDE).

The request message uses the following values for each of the EAPOL-Key frame fields:

Descriptor Type = N – see 12.7.2

Key Information:

Key Descriptor Version = 1 (ARC4 encryption with HMAC-MD5) or 2 (NIST AES key wrap with HMAC-SHA-1-128) or 3 (NIST AES key wrap with AES-128-CMAC), in all other cases 0

Key Type = 0 (Group/SMK)

SMK Message = 1 (SMK)

Install = 0

Key Ack = 0

Key MIC = 1

Secure = 1

Error = 1

Request = 1 when the message is going from the STA to an AP or 0 when the message is going from an AP to the STA

Encrypted Key Data = 0

Reserved = 0

Key Length = 0

Key Replay Counter = request EAPOL replay counter

KeyNonce = 0

EAPOL-Key IV = 0

Key RSC = 0

Key MIC = MIC computed over the body of this EAPOL-Key frame

Key Data Length = Length of Key Data field in octets

Key Data = Error KDE (different types defined in Table 12-7), MAC Address KDE

12.7.8.5.2 Error ERR_STA_NR

This error message is sent whenever an AP finds that the STA to which it needs to send a message is not reachable. In response to this error, the AP creates an Error KDE with error type ERR_STA_NR and sends the message back to the other STA involved in the handshake. The MAC address KDE contains the MAC address of the unreachable STA.

12.7.8.5.3 Error ERR_STA_NRSN

This error message is sent whenever the AP finds that the STA to which it needs to send the message does not have a secure RSNA connection. In response of this error, the AP creates an Error KDE with error type ERR_STA_NRSN and sends the message back to the STA from which it received the last message. The MAC address KDE contains the MAC address of the STA with which the AP does not have a secure RSNA connection.

12.7.8.5.4 Error ERR_CPHR_NS

This error message is sent whenever a STA finds that it does not support any of the cipher suites proposed by the other STA. In response to this error, the STA creates an Error KDE with error type ERR_CPHR_NS and sends the message back to the other STA. The MAC address KDE contains the MAC address of the other STA.

12.7.8.5.5 Error ERR_NO_STSL

This error message is sent whenever a STA finds that it does not have an existing STSL with the other STA. In response of this error, the STA creates an Error KDE with error type ERR_NO_STSL and sends the message back to the other STA. The MAC address KDE contains the MAC address of the other STA.

12.7.9 TDLS PeerKey (TPK) security protocol

12.7.9.1 General

The TPK security protocol is executed between the two non-AP STAs that intend to establish an RSNA for direct-link communication. If any security method (pre-RSNA or RSNA) is enabled on the connection between a STA and the AP, the STA shall require that the TPK security protocol complete successfully before using a direct link. If no security method is enabled on the connection between a STA and the AP, the STA shall not use the TPK security protocol on the direct link. A STA may refuse to set up a TDLS link when the protection on the STA link to the AP is secured with a weak algorithm or when the link between the STA and the AP is not using any security.

12.7.9.2 TPK handshake

The TPK handshake occurs as part of the TDLS direct-link setup procedure. The TPKSA is the result of the successful completion of the TPK handshake protocol, which derives keys for providing confidentiality and data origin authentication.

In order to maintain TPK confidentiality, both the TDLS initiator STA and the TDLS responder STAs establish an RSNA with their common AP prior to executing the TPK handshake. To meet this criterion, a STA may refuse to initiate the TDLS direct link if:

- a) The AP does not include an RSNE in its Beacon and Probe Response frames to advertise the availability of security;
- b) The AP's RSNE indicates that WEP-40 (OUI 00-0F-AC:1) or WEP-104 (OUI 00-0F-AC:5) are enabled as either pairwise or group cipher suites; or
- c) The AP's RSNE indicates that Use group cipher suite (00-0F-AC:0) is used as the pairwise cipher suite.

Violation of any of these cases would cause the TPK handshake to leak the TPK.

The TDLS initiator STA and the TDLS responder STA perform the following exchange to set up a TPK:

TDLS PMK handshake message 1: TDLS initiator STA → TDLS responder STA:

Link Identifier element, RSNE, Timeout Interval element, FTE

TDLS PMK handshake message 2: TDLS responder STA → TDLS initiator STA:

Link Identifier element, RSNE, Timeout Interval element, FTE

TDLS PMK handshake message 3: TDLS initiator STA → TDLS responder STA:

Link Identifier element, RSNE, Timeout Interval element, FTE

where

The TDLS initiator STA Address field of the Link Identifier element is the MAC address of the TDLS initiator STA

The TDLS responder STA Address field of the Link Identifier element is the MAC address of the TDLS responder STA

The PairwiseCipherSuite field of the RSNE identifies the cipher suite used to protect the Data frames sent over the direct link

The AKM suite list of the RSNE identifies which Authentication Method was used

The TimeoutIntervalType field of the Timeout Interval element is the key lifetime

The SNonce field of the FTE is a 256 bit value randomly generated by the TDLS initiator STA

The ANonce field of the FTE is a 256 bit value randomly generated by the TDLS responder STA (set to 0 in message 1)

The MIC field of the FTE is 0 for message 1 and computed as described in 12.7.9.4.3 and 12.7.9.4.4 for messages 2 and 3 respectively

The TDLS PMK handshake message 1 shall be transmitted in the TDLS Setup Request frame.

TDLS PMK handshake message 2 shall be transmitted in the TDLS Setup Response frame.

TDLS PMK handshake message 3 shall be transmitted in the TDLS Setup Confirm frame.

The TPK shall be derived as follows:

$$\text{TPK-Key-Input} = \text{Hash}(\min(\text{SNonce}, \text{ANonce}) \parallel \max(\text{SNonce}, \text{ANonce}))$$

$$\begin{aligned} \text{TPK} = & \text{KDF-Hash-Length}(\text{TPK-Key-Input}, "TDLS PMK", \min(\text{MAC_I}, \text{MAC_R}) \\ & \parallel \max(\text{MAC_I}, \text{MAC_R}) \parallel \text{BSSID}) \end{aligned}$$

where

Hash is the hash algorithm identified by the negotiated AKM suite selector specified in Table 9-133
 KDF-Hash-Length is the key derivation function defined in 12.7.1.7.2 that uses Hash to generate a key whose length is TK_bits + 128

TK_bits is cipher-suite specific and specified in Table 12-4

MAC_I and MAC_R are the MAC addresses of the TDLS initiator STA and the TDLS responder STA, respectively

SNonce and ANonce are the nonces generated by the TDLS initiator STA and TDLS responder STA, respectively, for this instance of the TPK handshake. The BSSID is set to the BSSID of the current association of the TDLS initiator STA.

Each TPK has two component keys—TPK-KCK and TPK-TK, defined as follows:

The Key Confirmation Key (KCK) shall be computed as the first 128 bits (bits 0–127) of the TPK

$$\text{TPK-KCK} = \text{L}(\text{TPK}, 0, 128)$$

The KCK is used to provide data origin authenticity in TDLS Setup Response and TDLS Setup Confirm frames.

The temporal key (TK) shall be computed as the remaining bits (for CCMP-128, the second 128 bits, i.e., bits 128–255) of the TPK

$$\text{TPK-TK} = \text{L}(\text{TPK}, 128, \text{Length} - 128)$$

The TPK-TK is used to provide confidentiality for direct-link data.

The temporal key is configured into the STA by the SME through the use of the MLME-SETKEYS.request primitive.

12.7.9.3 TPK handshake security assumptions

The security of the TDLS PMK handshake depends on the following:

- a) The TDLS initiator STA and the TDLS peer STA each have an RSNA established with the AP that is being used for TDLS Setup.
- b) The AP does not expose the nonces exchanged by the TDLS initiator STA and the TDLS responder STA to any external party.
- c) The AP does not use these nonces to derive the TPK and attack the TDLS direct-link instance.
- d) TDLS message security (encryption and integrity computations) processing at the AP is protected from illegal eavesdropping, alterations, insertions and substitutions.
- e) The TDLS initiator STA and TDLS responder STAs do not expose SNonce, ANonce, or the derived key to a third party.
- f) The TDLS initiator STA and the TDLS peer STA are associated to the same AP.

12.7.9.4 TPK Security Protocol handshake messages

12.7.9.4.1 Overview

The TPK handshake consists of three messages. Each message comprises a number of elements and is included in the TDLS Setup Request, TDLS Setup Response, and TDLS Setup Confirm.

In an RSN, these handshake messages serve to provide a session identifier, are identified by the nonces, and are used as association instance identifiers. These nonces are chosen randomly or pseudorandomly, and are used to generate the TPK.

12.7.9.4.2 TPK handshake message 1

If the TDLS initiator STA has security enabled on the link with the AP, it shall add an RSNE, FTE, and Timeout Interval element to its TDLS Setup Request frame. The elements shall be formatted as follows:

The RSNE, if present, shall be set as follows:

Version shall be set to 1.

The pairwise cipher suite list field indicating the pairwise cipher suites the TDLS initiator STA is willing to use with the TPKSA. WEP-40, WEP-104, and TKIP shall not be included in this list.

The group cipher suite shall be set to 00-0F-AC:7.

The AKM suite count field shall be set to 1.

The AKM suite list field shall be set to indicate TPK handshake (00-0F-AC:7).

In the RSN Capabilities field, the No Pairwise subfield shall be set to 0 and the PeerKey Enabled subfield shall be set to 1.

PMKID Count subfield, if present, shall be set to 0.

PMKID list shall not be present.

The Group Management Cipher Suite subfield, if present, shall be set to 00-0F-AC:7.

The Timeout Interval element indicates the lifetime of the TPKSA. The Lifetime Interval Type shall be set to ‘2’ (Key Lifetime Interval). The minimum lifetime shall be 300 seconds.

The FTE shall be set as follows:

SNonce shall be set to a value chosen randomly by the TDLS initiator STA, following the recommendations of 12.7.5.

All other fields shall be set to 0.

The TDLS initiator STA sends message 1 to the TDLS responder STA.

On reception of message 1, the TDLS responder STA checks whether the RSNE is present.

If the TDLS responder STA does not have security enabled on the link with the AP, it shall reject the request with status code SECURITY_DISABLED.

If the TDLS responder STA has security enabled on the link with the AP, it checks whether the request includes an RSNE and FTE. If not, the TDLS responder STA shall reject the request with status code INVALID_PARAMETERS.

If the version field of the RSNE is 0, then the TDLS responder STA shall reject the request with status code UNSUPPORTED_RSNE_VERSION.

Otherwise, the TDLS responder STA processes the message as follows:

If the contents of the RSNE do not indicate AKM of TPK handshake (suite type 00-0F-AC:7), the TDLS responder STA shall reject the request with status code STATUS_INVALID_AKMP.

If none of the pairwise cipher suites are acceptable, or pairwise ciphers include WEP-40, WEP-104, or TKIP, then the TDLS responder STA shall reject the TDLS Setup Request frame with status code STATUS_INVALID_PAIRWISE_CIPHER.

If the RSN Capabilities field has not set the subfields according to the described rules for this message, then the TDLS responder STA rejects with status code INVALID_RSNE_CAPABILITIES.

If the suggested lifetime is unacceptable or below the default value, the TDLS responder STA shall reject the TDLS Setup Request frame with status code UNACCEPTABLE_LIFETIME.

If the contents of the FTE are not as per specified for this message, then the TDLS responder STA shall reject the TDLS Setup Request frame with status code STATUS_INVALID_FTE.

The TDLS responder STA shall ignore the remaining fields in the RSNE, FTE, and Timeout Interval element.

Otherwise, the TDLS responder STA shall respond as specified in 11.23.4.

12.7.9.4.3 TPK handshake message 2

If the TDLS responder STA validates the TPK handshake message 1 for this TDLS instance, the TDLS responder STA may respond with TPK handshake message 2. To do so, the TDLS responder STA shall add an RSNE, FTE, and Timeout Interval element to its TDLS Setup Response frame. The elements shall be formatted as follows:

The RSNE shall include the following:

Include a pairwise cipher suite from one of those presented in RSNE of message 1 of this sequence in the pairwise cipher suite list, and set the pairwise cipher suite count to 1.

The version number shall be the minimum of the maximum version supported by the TDLS responder STA and the version number received in the RSNE of message 1.

All other RSNE fields shall be same as those received in message 1.

The Timeout Interval element shall be the same as that received in the TPK handshake message 1.

The FTE shall include the following:

ANonce shall be set to a value chosen randomly by the TDLS responder STA, following the recommendations of 12.7.5.

SNonce shall be same as that received in message 1 of this sequence

The MIC shall be calculated on the concatenation, in the following order, of:

TDLS initiator STA MAC address (6 octets)

TDLS responder STA MAC address (6 octets)

Transaction Sequence number (1 octet) which shall be set to the value 2

Link Identifier element

RSNE

Timeout Interval element

FTE, with the MIC field of the FTE set to 0.

The MIC shall be calculated using the TPK-KCK and the AES-128-CMAC algorithm. The output of the AES-128-CMAC shall be 128 bits.

All other fields shall be set to 0.

The TDLS responder STA shall use the MLME-SETKEYS.request primitive to configure the Temporal Key into its STA prior to sending message 2.

The TDLS responder STA sends message 2 to the TDLS initiator STA. The TDLS initiator STA shall process message 2 as follows:

If the TDLS initiator STA Address and TDLS responder STA Address of the Link Identifier element do not match those for an outstanding TDLS Setup Request, the TDLS initiator STA shall silently discard the received TDLS Setup Response frame.

If the SNonce field of the FTE does not match that of an outstanding request to the TDLS responder STA, then the TDLS initiator STA shall silently discard the received TDLS Setup Response frame.

Otherwise, the TDLS initiator STA shall compute the TPK and then validate the MIC in the FTE as specified in MIC calculation procedure for TPK handshake message 2. If invalid, the TDLS initiator STA shall discard the message.

If the version of the RSNE is 0 or is greater than the version of the RSNE sent in message 1, then the TDLS initiator STA shall reject the response with status code UNSUPPORTED_RSNE_VERSION. Otherwise,

If the contents of the RSNE, with the exception of the pairwise cipher suite count and pairwise cipher suite list are not the same as those sent by the TDLS initiator STA in message 1 of this sequence, then the TDLS initiator STA shall reject the response with status code INVALID_RSNE.

If the pairwise cipher suite count is other than 1, then the TDLS initiator STA shall reject the response with status code STATUS_INVALID_PAIRWISE_CIPHER.

If the selected pairwise cipher suite was not included in the Initiator's request, then the TDLS initiator STA shall reject the TDLS Setup Response frame with status code STATUS_INVALID_PAIRWISE_CIPHER.

If the Timeout Interval element is not the same as that sent in message 1, the TDLS initiator STA shall reject the TDLS Setup Response frame with status code UNACCEPTABLE_LIFETIME.

If the BSSID in the Link Identifier element is different from the one sent in message 1, then the TDLS initiator STA shall reject the response with status code NOT_IN_SAME_BSS.

If the TDLS initiator STA validates TDLS message 2, the TDLS initiator STA shall create a TPKSA and respond with message 3 as defined in 11.23.4. The TDLS initiator STA shall use the MLME-SETKEYS.request primitive to configure the Temporal Key into its STA prior to sending message 3.

12.7.9.4.4 TPK handshake message 3

If the TDLS initiator STA responds to message 2 for this TDLS instance, the TDLS initiator STA shall add an RSNE, FTE, and Timeout Interval element to its TDLS Setup Confirm frame. The elements shall be formatted as follows:

The RSNE shall be the same as the RSNE received in message 2.

The Timeout Interval element shall be the same as that received in the TPK handshake message 2.

With the exception of the MIC field, the contents of the FTE shall be the same as the FTE received in message 2.

The MIC shall be calculated on the concatenation, in the following order, of:

TDLS initiator STA MAC address (6 octets)

TDLS responder STA MAC address (6 octets)

Transaction Sequence number (1 octet), which shall be set to the value 3

Link Identifier element

RSNE

Timeout Interval element

FTE, with the MIC field of the FTE set to 0.

The MIC shall be calculated using the TPK-KCK and the AES-128-CMAC algorithm. The output of the AES-128-CMAC shall be 128 bits.

All other fields shall be set to 0.

The TDLS initiator STA sends message 3 to the TDLS responder STA. The TDLS responder STA shall process message 3 as follows:

If the Source and Destination Addresses of the Link Identifier element do not match those for an outstanding TDLS Setup Request, the TDLS responder STA shall discard the message.

If the ANonce and SNonce fields of the FTE do not match that of an outstanding request to the TDLS initiator STA, then the TDLS responder STA shall discard the message.

Otherwise, the TDLS responder STA shall validate the MIC in the FTE as specified in the MIC calculation procedure for TPK handshake message 3. If invalid, the TDLS responder STA shall discard the message.

The TDLS responder STA shall discard the message, the TDLS responder STA shall abandon the TPK handshake identified by the $\langle A\text{Nonce}, S\text{Nonce} \rangle$ combination, and delete existing TPK handshake key state for this sequence if any of the following checks fail:

The contents of the RSNE are not the same as that sent by the TDLS responder STA in message 2

The Timeout Interval element is not the same as that sent in message 2

The BSSID from the Link Identifier element is not the same as that sent in message 2

On successful processing of message 3, the TPK handshake is considered successful.

The TPKSA shall be deleted by the TDLS responder STA if it does not receive a valid TPK handshake message 3 from the TDLS Initiator STA within `dot11TDLSResponseTimeout`.

12.7.9.5 Supplicant state machine procedures

The following list summarizes the procedures used by the Supplicant state machine:

- **STADisconnect** – The Supplicant invokes this procedure to disassociate and deauthenticate its STA from the AP.
- **MIC(x)** – The Supplicant invokes this procedure to compute a MIC of the data x .
- **CheckMIC()** – The Supplicant invokes this procedure to verify a MIC computed by the MIC() function.
- **StaProcessEAPOL-Key** – The Supplicant invokes this procedure to process a received EAPOL-Key frame. The pseudocode for this procedure is as follows:

StaProcessEAPOL-Key ($S, M, A, I, K, RSC, A\text{Nonce}, \text{RSC}, \text{MIC}, \text{RSNE}, \text{GTK}[N], \text{IGTK}[M], \text{IPN}$)

```

 $TPTK \leftarrow PTK$ 
 $TS\text{Nonce} \leftarrow 0$ 
 $PRSC \leftarrow 0$ 
 $UpdatePTK \leftarrow 0$ 
 $State \leftarrow \text{UNKNOWN}$ 
if  $M = 1$  then
    if Check MIC( $PTK, EAPOL\text{-Key frame}$ ) fails then
         $State \leftarrow \text{FAILED}$ 
    else
         $State \leftarrow \text{MICOK}$ 
    endif
endif
if  $K = P$  then
    if  $State \neq \text{FAILED}$  then
        if PSK exists then – PSK is a preshared key
             $PMK \leftarrow PSK$ 
        else
             $PMK \leftarrow L(\text{MSK}, 0, \text{PMK\_bits})$ 
        endif
         $TS\text{Nonce} \leftarrow S\text{Nonce}$ 
        if  $A\text{Nonce} \neq PreA\text{Nonce}$  then
             $TPTK \leftarrow \text{Calc PTK}(PMK, A\text{Nonce}, TS\text{Nonce})$ 
             $PreA\text{Nonce} \leftarrow A\text{Nonce}$ 
        endif
    endif

```

```

if State = MICOK then
     $PTK \leftarrow TPTK$ 
     $UpdatePTK \leftarrow I$ 
    if  $UpdatePTK = 1$  then
        if no  $GTK$  then
             $PRSC \leftarrow RSC$ 
        endif
        if MLME-SETKEYS.request(0, true,  $PRSC$ ,  $PTK$ ) fails then
            invoke MLME-
                DEAUTHENTICATE.request
        endif
         $MLME-SETPROTECTION.request(TA, Rx)$ 
    endif
    if  $GTK$  then
        if ( $GTK[N] \leftarrow$  Decrypt  $GTK$ ) succeeds then
            if MLME-SETKEYS.request( $N$ , 0,  $RSC$ ,  $GTK[N]$ ) fails then
                invoke MLME-DEAUTHENTICATE.request
            endif
        else
             $State \leftarrow FAILED$ 
        endif
    endif
    if  $IGTK$  then
        if ( $IGTK[M] \leftarrow$  Decrypt  $IGTK$ ) succeeds then
            if MLME-SETKEYS.request( $M$ , 0, IPN,  $IGTK[M]$ ) fails then
                invoke MLME-DEAUTHENTICATE.request
            endif
        else
             $State \leftarrow FAILED$ 
        endif
    endif
    endif
endif
else if KeyData =  $GTK$  then
    if State = MICOK then
        if ( $GTK[N] \leftarrow$  Decrypt  $GTK$ ) succeeds then
            if MLME-SETKEYS.request( $N$ ,  $T$ ,  $RSC$ ,  $GTK[N]$ ) fails then
                invoke MLME-DEAUTHENTICATE.request
            endif
        else
             $State \leftarrow FAILED$ 
        endif
        if ( $IGTK[M] \leftarrow$  Decrypt  $IGTK$ ) succeeds then
            if MLME-SETKEYS.request( $M$ ,  $T$ , IPN,  $IGTK[M]$ ) fails then
                invoke MLME-DEAUTHENTICATE request
            endif
        else
             $State \leftarrow FAILED$ 
        endif
    else
         $State \leftarrow FAILED$ 
    endif
endif
endif
if  $A = 1 \&& State \neq Failed$  then

```

```

        Send EAPOL-Key(0,1,0,0,K,0,0,TSNonce,MIC(TPTK),RSNE)
endif
if UpdatePTK = 1 then
        MLME-SETPROTECTION.request(TA, Rx_Tx)
endif
if State = MICOK && S = 1 then
        MLME-SETPROTECTION.request(TA, Rx_Tx)
        if IBSS then
            keycount++
            if keycount = 2 then
                802.1X::portValid ← true
            endif
        else
            802.1X::portValid ← true
        endif
    endif

```

Here UNKNOWN, MICOK, and FAILED are values of the variable State used in the Supplicant pseudocode. State is used to decide how to do the key processing. MICOK is set to 1 when the MIC of the EAPOL-Key has been checked and is valid. FAILED is used when a failure has occurred in processing the EAPOL-Key frame. UNKNOWN is the initial value of the variable State.

When processing 4-way handshake message 3, the GTK and IGTK are decrypted from the EAPOL-Key frame and installed. The PTK shall be installed before the GTK and IGTK.

The Key Replay Counter field used by the Supplicant for EAPOL-Key frames that are sent in response to a received EAPOL-Key frame shall be the received Key Replay Counter field. Invalid EAPOL-Key frames such as invalid MIC, GTK without a MIC, etc., shall be ignored.

NOTE 1—TPTK is used to stop attackers changing the PTK on the Supplicant by sending the first message of the 4-way handshake. An attacker can still affect the 4-way handshake while the 4-way handshake is being carried out.

NOTE 2—The PMK is supplied by the authentication method used with IEEE Std 802.1X-2010 if preshared mode is not used.

NOTE 3—A PTK is configured into the encryption/integrity engine depending on the Tx/Rx bit, but if configured, is always a transmit key. A GTK is configured into the encryption/integrity engine independent of the state of the Tx/Rx bit, but whether the GTK is used as a transmit key is dependent on the state of the Tx/Rx bit.

- **CalcGTK(x)** – Generates the GTK.
- **DecryptGTK(x)** – Decrypt the GTK from the EAPOL-Key frame.
- **DecryptIGTK(x)** – Decrypt the IGTK from the EAPOL-Key frame.

12.7.9.6 Supplicant PeerKey state machine states

Figure 12-48 depicts the PeerKey handshake Supplicant key management state machine. The following list summarizes the states the Supplicant state machine uses to support the PeerKey handshake:

- **STKINIT:** This state is the idle state and is entered when the IEEE 802.1X Supplicant completes successful Authentication.
- **SMKNEGOTIATING1:** This state is entered when the MLME-STKSTART.request primitive is received for the SMK handshake by the initiator STA.
- **SMKNEGOTIATING2:** This state is entered when the first EAPOL-Key frame of the SMK handshake is received by the peer STA.
- **SMKNEGOTIATING3:** This state is entered when the fifth EAPOL-Key frame of the SMK handshake is received by the initiator STA.
- **SMKNEGOTIATING4:** This state is entered when the fourth EAPOL-Key frame of the SMK handshake is received by the peer STA.

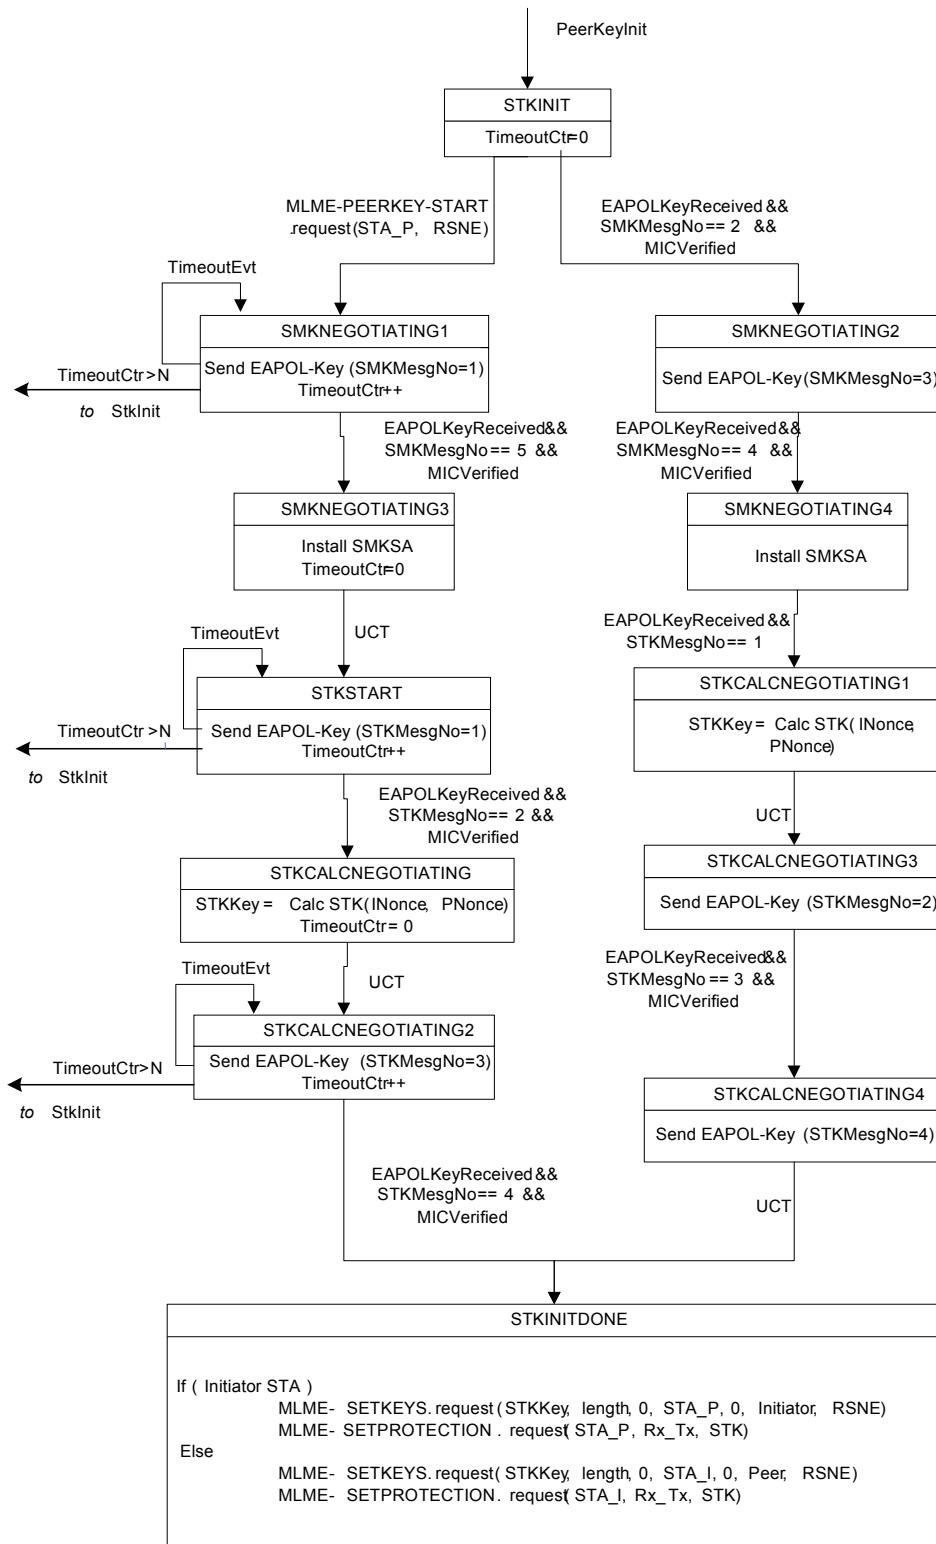

Figure 12-48—PeerKey handshake Supplicant key management state machine

- **STKSTART:** Once the SMKSA is created, the initiator STA enters this state. This is the start of 4-Way STK handshake.
- **STKCALCNEGOTIATING:** This state is entered when the second EAPOL-Key frame of the 4-Way STK handshake is received by the initiator STA and the MIC is verified.
- **STKCALCNEGOTIATING1:** This state is entered when the first EAPOL-Key frame of the 4-Way STK handshake is received by the peer STA and the MIC is verified.
- **STKCALCNEGOTIATING2:** This state is entered unconditionally by the initiator STA.
- **STKCALCNEGOTIATING3:** This state is entered unconditionally by the peer STA.
- **STKCALCNEGOTIATING4:** This state is entered when the third EAPOL-Key frame of the 4-Way STK handshake is received by the peer STA and the MIC is verified.
- **STKINITDONE:** This state is entered by the initiator STA when the fourth EAPOL-Key frame of the 4-way STK handshake is received. This state is entered by the peer STA when the fourth EAPOL-Key frame of the 4-way STK handshake is sent.

12.7.9.7 Supplicant PeerKey state machine variables

The following list summarizes the variables used by the Supplicant state machine:

- *PeerKeyInit* – This variable is used to initialize the PeerKey state machine.
- *TimeoutEvt* – This variable is set to true if the EAPOL-Key frame sent fails to obtain a response from the Supplicant. The variable may be set by management action or set by the operation of a timeout while in the different states.
- *TimeoutCtr* – This variable maintains the count of EAPOL-Key receive timeouts. It is incremented each time a timeout occurs on EAPOL-Key receive event and is initialized to 0. The Key Replay Counter field value for the EAPOL-Key frame shall be incremented on each transmission of the EAPOL-Key frame.
- *MICVerified* – This variable is set to true if the MIC on the received EAPOL-Key frame is verified and is correct. Any EAPOL-Key frames with an invalid MIC are dropped and ignored.
- *SMKMesgNo* – This variable indicates SMK handshake EAPOL-Key frame types. Details for each message type (1-5) are provided in 12.7.8.
- *STKMesgNo* – This variable indicates 4-way STK handshake EAPOL-Key frame types. Details for each message type (1-4) are provided in 12.7.6.
- *STA_P* – This variable indicates the MAC address of the peer STA participating in the PeerKey handshake.
- *STA_I* – This variable indicates the MAC address of the initiator STA participating in the PeerKey handshake.
- *STKKey* – The STK generated as a result of the 4-way STK handshake.
- *EAPOLKeyReceived* – The Supplicant sets this variable to true when it receives an EAPOL-Key frame.

12.7.10 RSNA Supplicant key management state machine

12.7.10.1 General

The Supplicant shall reinitialize the Supplicant state machine whenever its system initializes. A Supplicant enters the AUTHENTICATION state on an event from the MAC that requests another STA to be authenticated. A Supplicant enters the STAKEYSTART state on receiving an EAPOL-Key frame from the Authenticator. If the MIC or any of the EAPOL-Key frames fails, the Supplicant silently discards the frame. Figure 12-49 depicts the RSNA Supplicant state machine.

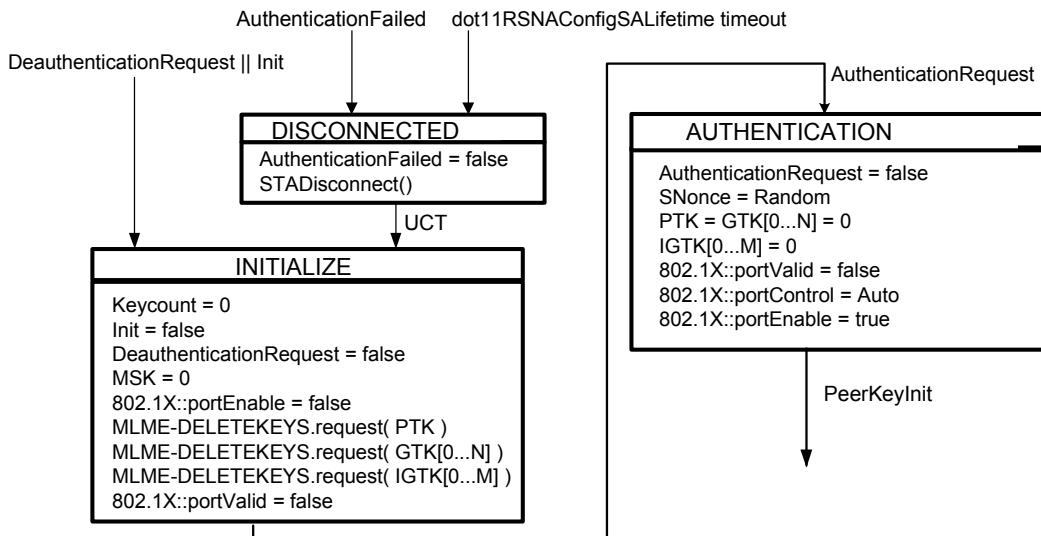

Figure 12-49—RSNA Supplicant key management state machine

Unconditional transfer (UCT) means the event triggers an immediate transition.

This state machine does not use timeouts or retries. The IEEE 802.1X state machine has timeouts that recover from authentication failures, etc.

In order to authenticate an Authenticator, the management entity sends an authentication request event. This might be before or after the STA associates to the AP. In an IBSS environment, the event is generated when a Probe Response frame is received.

12.7.10.2 Supplicant state machine states

The following list summarizes the states of the Supplicant state machine:

- **AUTHENTICATION:** A Supplicant enters this state when it sends an IEEE 802.1X AuthenticationRequest to authenticate to an SSID.
- **DISCONNECTED:** A Supplicant enters this state when IEEE 802.1X authentication fails. The Supplicant executes StaDisconnect and enters the INITIALIZE state.
- **INITIALIZE:** A Supplicant enters this state from the DISCONNECTED state, when it receives Disassociation or Deauthentication messages or when the STA initializes, causing the Supplicant to initialize the key state variables.
- **STAKEYSTART:** A Supplicant enters this state when it receives an EAPOL-Key frame. All the information to process the EAPOL-Key frame is in the message and is described in the StaProcessEAPOL-Key procedure.

12.7.10.3 Supplicant state machine variables

The following list summarizes the variables used by the Supplicant state machine:

- *DeauthenticationRequest* – The Supplicant sets this variable to true if the Supplicant’s STA reports it has received Disassociation or Deauthentication messages.
- *AuthenticationRequest* – The Supplicant sets this variable to true if its STA’s IEEE 802.11 management entity reports that an SSID is to be authenticated. This might be on association or at other times.

- *AuthenticationFailed* – The Supplicant sets this variable to true if the IEEE 802.1X authentication failed. The Supplicant uses the MLME-DISASSOCIATE.request primitive to cause its STA to disassociate from the Authenticator’s STA.
- *EAPOLKeyReceived* – The Supplicant sets this variable to true when it receives an EAPOL-Key frame.
- *IntegrityFailed* – The Supplicant sets this variable to true when its STA reports that a fatal data integrity error (e.g., michael failure) has occurred.

NOTE—A michael failure is not the same as MICVerified because IntegrityFailed is generated if the michael integrity check fails; MICVerified is generated from validating the EAPOL-Key integrity check. Note also the STA does not generate this event for ciphers other than TKIP because countermeasures are not required.

- *MICVerified* – The Supplicant sets this variable to true if the MIC on the received EAPOL-Key frame verifies as correct. The Supplicant silently discards any EAPOL-Key frame received with an invalid MIC.
- *SNonce* – This variable represents the Supplicant’s nonce.
- *PTK* – This variable represents the current PTK.
- *TPTK* – This variable represents the current PTK until message 3 of the 4-way handshake arrives and is verified.
- *GTK[]* – This variable represents the current GTKs for each group key index.
- *IGTK[]* – This variable represents the current IGTKs for each group management key index.
- *PMK* – This variable represents the current PMK.
- *keycount* – This variable is used in IBSS mode to decide when all of the keys have been delivered and an IBSS link is secure.
- *802.1X::XXX* – This variable denotes another IEEE 802.1X state variable *XXX* not specified in this standard.

12.7.11 RSNA Authenticator key management state machine

12.7.11.1 General

There is one state diagram for the Authenticator. In an infrastructure BSS, the Authenticator is always on the AP; and in an IBSS environment, the Authenticator is on every STA.

The state diagram shown in parts in Figure 12-50 to Figure 12-53 consists of the following states:

- a) The AUTHENTICATION, AUTHENTICATION2, INITPMK, INITPSK, PTKSTART, PTKCALCNEGOTIATING, PTKCALCNEGOTIATING2, PTKINITNEGOTIATING, PTKINITDONE, DISCONNECT, DISCONNECTED, and INITIALIZE states. These states handle the initialization, 4-way handshake, teardown, and general clean-up. These states are per associated STA.
- b) The IDLE, REKEYNEGOTIATING, KEYERROR, and REKEYESTABLISHED states. These states handle the transfer of the GTK to the associated client. These states are per associated STA.
- c) The GTK_INIT, SETKEYS, and SETKEYSDONE states. These states change the GTK when required, trigger all of the PTK group key state machines, and update the IEEE 802.11 MAC in the Authenticator’s AP when all STAs have the updated GTK. These states are global to the Authenticator.

Because there are two GTKs, responsibility for updating these keys is given to the group key state machine (see Figure 12-52). In other words, this state machine determines which GTK is in use at any time.

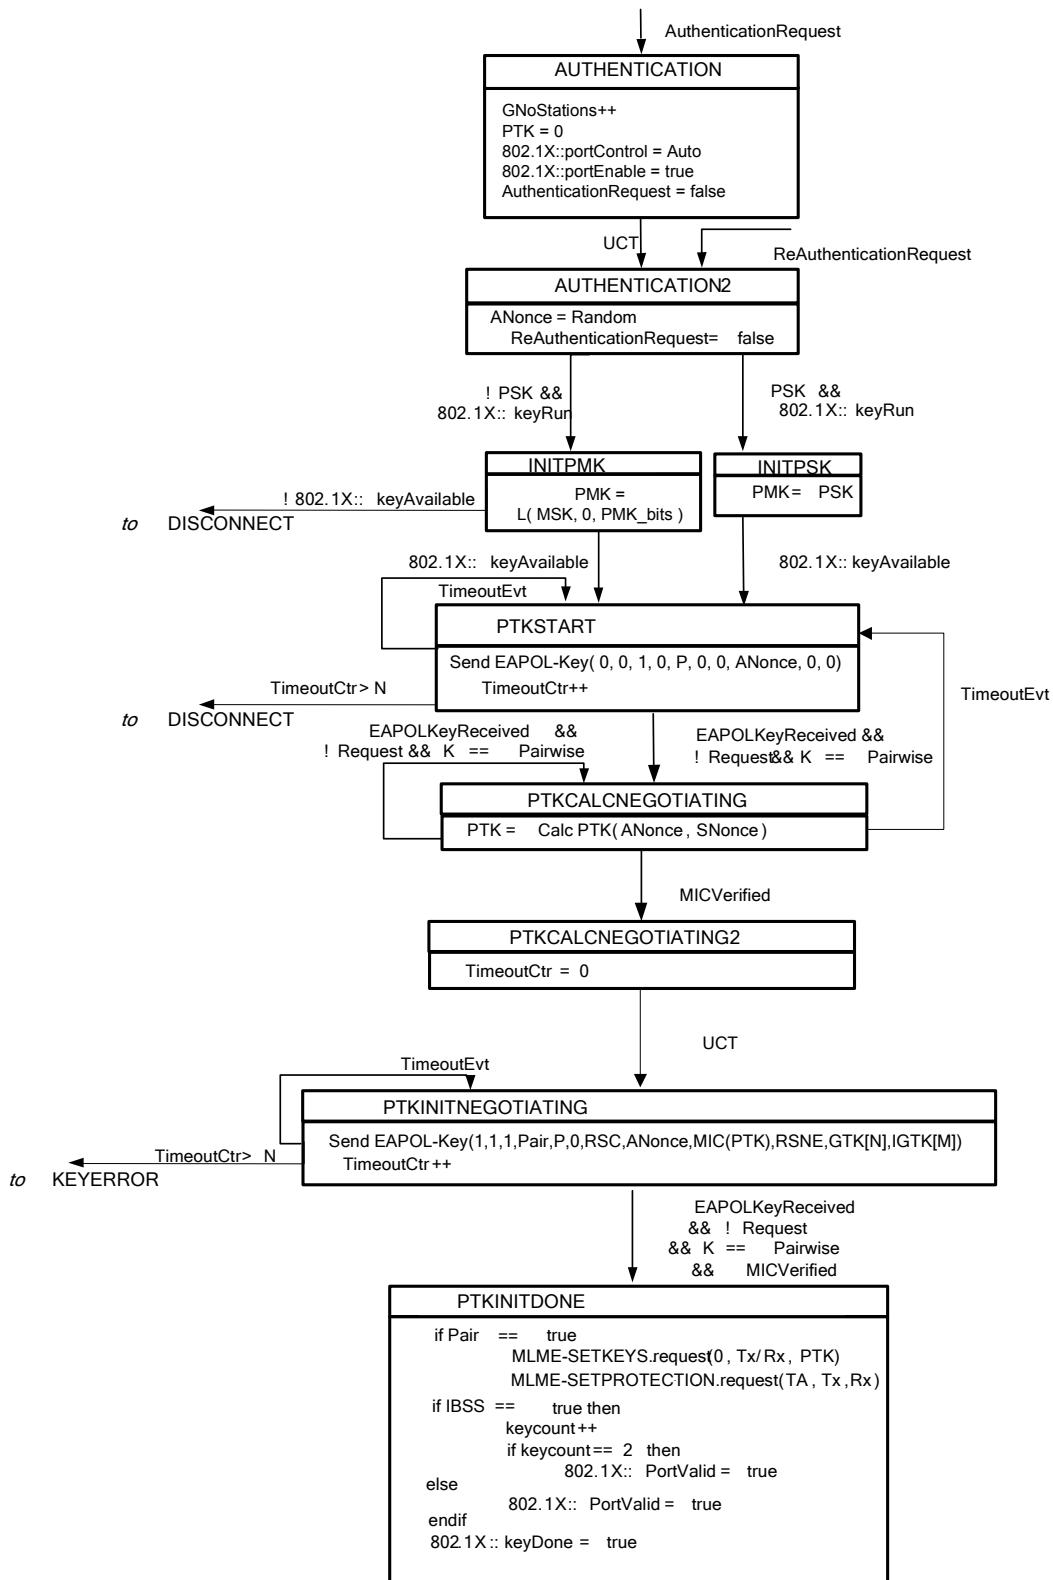

Figure 12-50—Authenticator state machines, part 1

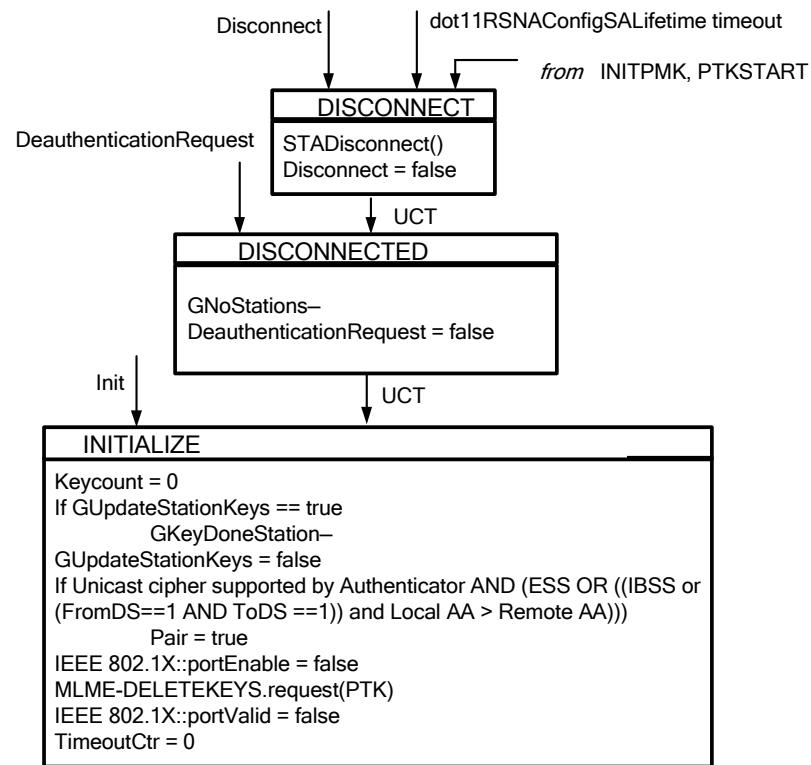

Figure 12-51—Authenticator state machines, part 2

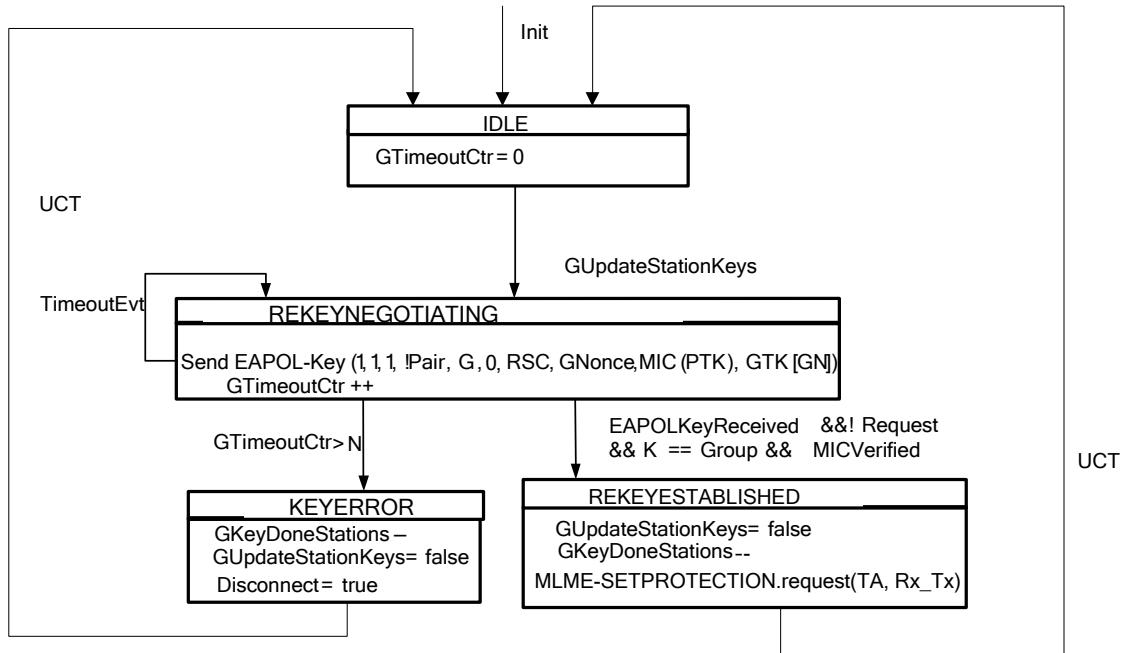

Figure 12-52—Authenticator state machines, part 3

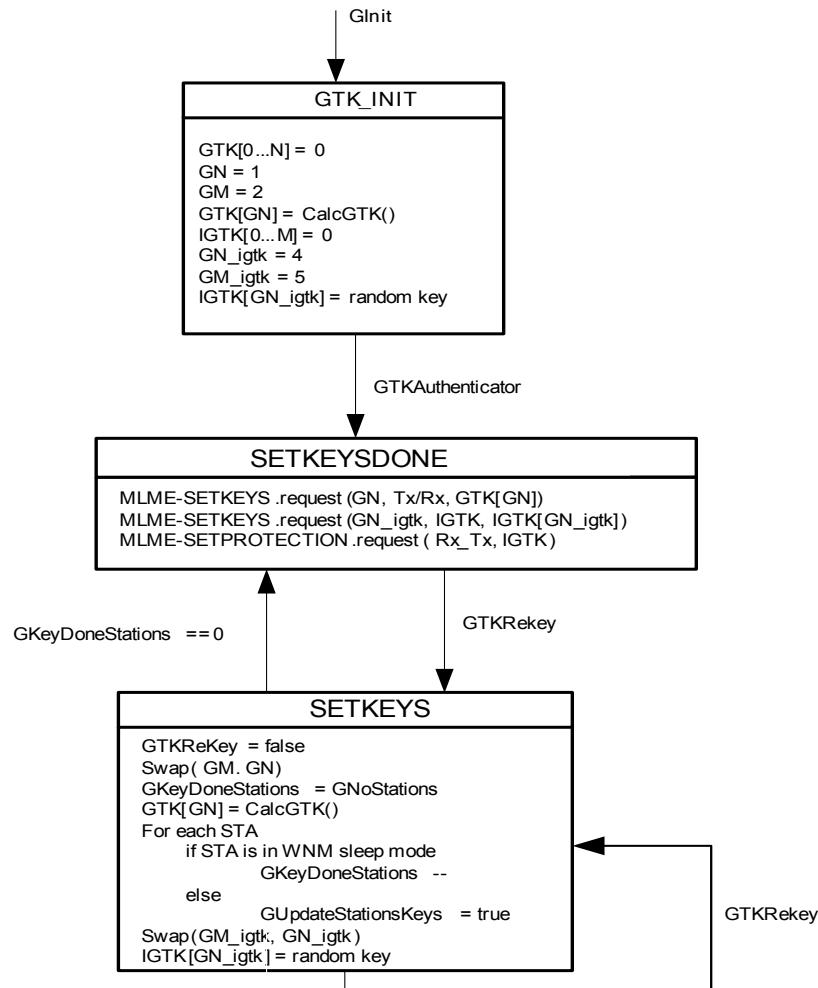

Figure 12-53—Authenticator state machines, part 4

When a second STA associates, the group key state machine is already initialized, and a GTK is already available and in use.

When the GTK is to be updated the variable **GTKReKey** is set to 1. The **SETKEYS** state updates the GTK and triggers all of the PTK group key state machines that currently exist—one per associated STA. Each PTK group key state machine sends the GTK to its STA. When all of the STAs have received the GTK (or failed to receive the key), the **SETKEYSDONE** state is executed which updates the APs encryption/integrity engine with the new key.

Both the PTK state machine and the PTK group key state machine use received EAPOL-Key frames as an event to change states. The PTK state machine only uses EAPOL-Key frames with the Key Type field equal to Pairwise, and the PTK group key state machine only uses EAPOL-Key frames with the Key Type field equal to Group.

12.7.11.2 Authenticator state machine states

12.7.11.2.1 Authenticator state machine: 4-way handshake (per STA)

The following list summarizes the states the Authenticator state machine uses to support the 4-way handshake:

- **AUTHENTICATION:** This state is entered when an AuthenticationRequest is sent from the management entity to authenticate a BSSID.
- **AUTHENTICATION2:** This state is entered from the AUTHENTICATION state or from the PTKINITDONE state.
- **DISCONNECT:** This state is entered if an EAPOL-Key frame is received and fails its MIC check. It sends a Deauthentication message to the STA and enters the INITIALIZE state.
- **DISCONNECTED:** This state is entered when Disassociation or Deauthentication messages are received.
- **INITIALIZE:** This state is entered from the DISCONNECTED state, when a deauthentication request event occurs, or when the STA initializes. The state initializes the key state variables.
- **INITPMK:** This state is entered when the IEEE 802.1X backend AS completes successfully. If a PMK is supplied, it goes to the PTKSTART state; otherwise, it goes to the DISCONNECTED state.
- **INITPSK:** This state is entered when a PSK is configured.
- **PTKCALCNEGOTIATING:** This state is entered when the second EAPOL-Key frame for the 4-way handshake is received with the key type of Pairwise.
- **PTKCALNEGOTIATING2:** This state is entered when the MIC for the second EAPOL-Key frame of the 4-way handshake is verified.
- **PTKINITNEGOTIATING:** This state is entered when the MIC for the second EAPOL-Key frame for the 4-way handshake is verified. When message 3 of the 4-way handshake is sent in state PTKINITNEGOTIATING, the encrypted GTK shall be sent at the end of the data field, and the GTK length is put in the GTK Length field.
- **PTKINITDONE:** This state is entered when the last EAPOL-Key frame for the 4-way handshake is received with the key type of Pairwise. This state may call SetPTK; if this call fails, the AP should detect and recover from the situation, for example, by doing a disconnect event for this association.
- **PTKSTART:** This state is entered from INITPMK or INITPSK to start the 4-way handshake or if no response to the 4-way handshake occurs.

12.7.11.2.2 Authenticator state machine: group key handshake (per STA)

The following list summarizes the states the Authenticator state machine uses to support the group key handshake:

- **IDLE:** This state is entered when no group key handshake is occurring.
- **KEYERROR:** This state is entered if the EAPOL-Key acknowledgment for the group key handshake is not received.
- **REKEYESTABLISHED:** This state is entered when an EAPOL-Key frame is received from the Supplicant with the Key Type subfield equal to Group.
- **REKEYNEGOTIATING:** This state is entered when the GTK is to be sent to the Supplicant.

NOTE—The Rx_Tx flag for sending a GTK is always the opposite of whether the pairwise key is used for data encryption/integrity or not. If a pairwise key is used for encryption/integrity, then the STA never transmits with the GTK; otherwise, the STA uses the GTK for transmit.

12.7.11.2.3 Authenticator state machine: group key handshake (global)

The following list summarizes the states the Authenticator state machine uses to coordinate a group key update of all STAs:

- **GTK_INIT**: This state is entered on system initialization.
- **SETKEYS**: This state is entered if the GTK is to be updated on all Supplicants.
- **SETKEYSDONE**: This state is entered if the GTK has been updated on all Supplicants.

NOTE—SETKEYSDONE calls SetGTK to set the GTK for all associated STAs that are not in WNM sleep mode. If this fails, all communication via this key fails, and the AP needs to detect and recover from this situation. A STA that is in WNM sleep mode will not have the current GTK installed when it wakes up and will need to get new GTK as described in the WNM sleep mode procedures in 11.2.3.18.

12.7.11.3 Authenticator state machine variables

The following list summarizes the variables used by the Authenticator state machine:

- *AuthenticationRequest* – This variable is set to true by the STA’s IEEE 802.11 management entity in order to authenticate an association. This can be set to true when the STA associates or at other times.
- *ReAuthenticationRequest* – This variable is set to true if the IEEE 802.1X Authenticator received an eapStart or 802.1X::reAuthenticate is 1.
- *DeauthenticationRequest* – This variable is set to true if a Disassociation or Deauthentication message is received.
- *Disconnect* – This variable is set to true when the STA should initiate a deauthentication.
- *EAPOLKeyReceived* – This variable is set to true when an EAPOL-Key frame is received. EAPOL-Key frames that are received in response to an EAPOL-Key frame sent by the Authenticator shall contain the same Key Replay Counter field value as the Key Replay Counter field in the transmitted message. EAPOL-Key frames that contain different Key Replay Counter field values should be discarded. An EAPOL-Key frame that is sent by the Supplicant in response to an EAPOL-Key frame from the Authenticator shall not have the Ack bit set to 1. EAPOL-Key frames sent by the Supplicant not in response to an EAPOL-Key frame from the Authenticator shall have the Request bit set to 1.
EAPOL-Key frames with a key type of Pairwise and a nonzero key index should be ignored.
EAPOL-Key frames with a key type of Group and an invalid key index should be ignored.

NOTE—When an EAPOL-Key frame in which the Ack bit is 0 is received, then it is expected as a reply to a message that the Authenticator sent, and the replay counter is checked against the replay counter used in the sent EAPOL-Key frame. When an EAPOL-Key frame in which the Request bit is 1 is received, then a replay counter for these messages is used that is a different replay counter than the replay counter used for sending messages to the Supplicant.

- *GTimeoutCtr* – This variable maintains the count of EAPOL-Key receive timeouts for the group key handshake. It is incremented each time a timeout occurs on EAPOL-Key receive event and is initialized to 0. Annex C details the timeout values. The Key Replay Counter field value for the EAPOL-Key frame shall be incremented on each transmission of the EAPOL-Key frame.
- *GInit* – This variable is used to initialize the group key state machine. This is a group variable.
- *Init* – This variable is used to initialize per-STA state machine
- *TimeoutEvt* – This variable is set to true if the EAPOL-Key frame sent out fails to obtain a response from the Supplicant. The variable may be set to 1 by management action or set to 1 by the operation of a timeout while in the PTKSTART and REKEYNEGOTIATING states.
- *TimeoutCtr* – This variable maintains the count of EAPOL-Key receive timeouts. It is incremented each time a timeout occurs on EAPOL-Key receive event and is initialized to 0. Annex C contains details of the timeout values. The Key Replay Counter field value for the EAPOL-Key frame shall be incremented on each transmission of the EAPOL-Key frame.

- *MICVerified* – This variable is set to true if the MIC on the received EAPOL-Key frame is verified and is correct. Any EAPOL-Key frames with an invalid MIC are dropped and ignored.
- *GTKAuthenticator* – This variable is set to true if the Authenticator is on an AP or it is the designated Authenticator for an IBSS.
- *GKeyDoneStations* – Count of number of STAs left to have their GTK updated. This is a global variable.
- *GTKRekey* – This variable is set to true when a group key handshake is required. This is a global variable.
- *GUpdateStationKeys* – This variable is set to true when a new GTK is available to be sent to Supplicants.
- *GNoStations* – This variable counts the number of Authenticators so it is known how many Supplicants need to be sent the GTK. This is a global variable.
- *ANonce* – This variable holds the current nonce to be used if the STA is an Authenticator.
- *GN, GM* – These are the current key indices for GTKs. Swap(GM, GN) means that the global key index in GN is swapped with the global key index in GM, so now GM and GN are reversed.
- *PTK* – This variable is the current PTK.
- *GTK[]* – This variable is the current GTKs for each GTK index.
- *PMK* – This variable is the buffer holding the current PMK.
- *802.1X::XXX* – This variable is the IEEE 802.1X state variable *XXX*.
- *keycount* – This variable is used in IBSS mode to decide when all of the keys have been delivered and an IBSS link is secure.
- *WNM sleep mode* – This variable is true when the non-AP STA is in the WNM sleep mode, as described in 11.2.3.18. Otherwise, it is false.

12.7.11.4 Authenticator state machine procedures

The following list summarizes the procedures used by the Authenticator state machine:

- **STADisconnect()** – Execution of this procedure deauthenticates the STA.
- **CalcGTK(x)** – Generates the GTK.
- **MIC(x)** – Computes a MIC over the plaintext data.

12.8 Mapping EAPOL keys to IEEE 802.11 keys

12.8.1 Mapping PTK to TKIP keys

See 12.7.1.3 for the definition of the EAPOL temporal key derived from PTK.

A STA shall use bits 0–127 of the temporal key as its input to the TKIP Phase 1 and Phase 2 mixing functions.

A STA shall use bits 128–191 of the temporal key as the michael key for MSDUs from the Authenticator’s STA to the Supplicant’s STA.

A STA shall use bits 192–255 of the temporal key as the michael key for MSDUs from the Supplicant’s STA to the Authenticator’s STA.

12.8.2 Mapping GTK to TKIP keys

See 12.7.1.4 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use bits 0–127 of the temporal key as the input to the TKIP Phase 1 and Phase 2 mixing functions.

A STA shall use bits 128–191 of the temporal key as the michael key for MSDUs from the Authenticator's STA to the Supplicant's STA.

A STA shall use bits 192–255 of the temporal key as the michael key for MSDUs from the Supplicant's STA to the Authenticator's STA.

12.8.3 Mapping PTK to CCMP keys

See 12.7.1.3 for the definition of the EAPOL temporal key derived from PTK.

A STA shall use the temporal key as the CCMP key for MPDUs between the two communicating STAs.

12.8.4 Mapping GTK to CCMP keys

See 12.7.1.4 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use the temporal key as the CCMP key.

12.8.5 Mapping GTK to WEP-40 keys

See 12.7.1.4 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use bits 0–39 of the temporal key as the WEP-40 key.

12.8.6 Mapping GTK to WEP-104 keys

See 12.7.1.4 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use bits 0–103 of the temporal key as the WEP-104 key.

12.8.7 Mapping IGTK to BIP keys

See 12.7.1.5 for the definition of the IGTK. A STA shall use bits 0–127 of the IGTK as the AES-128-CMAC key, bits 0–127 of the IGTK as the AES-128-GMAC key, and bits 0–255 of the IGTK as the AES-256-GMAC key.

12.8.8 Mapping PTK to GCMP keys

See 12.7.1.3 for the definition of the EAPOL temporal key derived from PTK.

A STA shall use the temporal key as the GCMP key for MPDUs between the two communicating STAs.

12.8.9 Mapping GTK to GCMP keys

See 12.7.1.4 for the definition of the EAPOL temporal key derived from GTK.

A STA shall use the temporal key as the GCMP key.

12.9 Per-frame pseudocode

12.9.1 WEP frame pseudocode

A WEP-encapsulated MPDU is called a *WEP MPDU*. All other MPDUs are called *non-WEP MPDUs*.

A STA shall not transmit WEP MPDUs when dot11PrivacyInvoked is false. This MIB variable does not affect the reception of frames containing all or part of an MSDU or MMPDU.

```

if dot11PrivacyInvoked is false then
    the MPDU is transmitted without WEP cryptographic encapsulation
else
    if (the MPDU has an individual RA and there is an entry in dot11WEPKeyMappings for that
        RA) then
        if that entry has WEPOn equal to false then
            the MPDU is transmitted without WEP cryptographic encapsulation
        else
            if that entry contains a key that is null then
                discard the MPDU's entire MSDU and generate an MA-UNITDATA-
                STATUS.indication primitive to notify LLC that the MSDU was
                undeliverable due to a null WEP key
            else
                encrypt the MPDU using that entry's key, setting the Key ID subfield of the IV
                field to 0
            endif
        endif
    else
        if (the MPDU has a group RA and the Privacy subfield of the Capability Information field
            in this BSS is 0) then
            the MPDU is transmitted without WEP cryptographic encapsulation
        else
            if dot11WEPDefaultKeys[dot11WEPDefaultKeyID] is null then
                discard the MPDU's entire MSDU and generate an MA-UNITDATA-
                STATUS.indication primitive to notify LLC that the MSDU was
                undeliverable due to a null WEP key
            else
                WEP-encapsulate the MPDU using the key dot11WEPDefaultKeys-
                [dot11WEPDefaultKeyID], setting the Key ID subfield of the IV field to
                dot11WEPDefaultKeyID
            endif
        endif
    endif
endif

```

When the boolean dot11ExcludeUnencrypted is true, MPDUs with the Type subfield equal to Data and the Protected Frame subfield of the Frame Control field equal to 0 shall not be indicated at the MAC service interface, and only MSDUs successfully reassembled from successfully decrypted MPDUs shall be indicated at the MAC service interface. When receiving a frame with the Type subfield equal to Data, the values of dot11PrivacyOptionImplemented, dot11WEPKeyMappings, dot11WEPDefaultKeys, dot11WEPDefaultKeyID, and dot11ExcludeUnencrypted in effect at the time the PHY-RXSTART.indication primitive is received by the MAC shall be used according to the following decision tree:

```

if the Protected Frame subfield of the Frame Control field is 0 then
    if dot11ExcludeUnencrypted is true then

```

```

        discard the frame body without indication to LLC and increment
        dot11WEPExcludedCount
    else
        receive the frame without WEP decapsulation
    endif
else
    if dot11PrivacyOptionImplemented is true then
        if (the MPDU has individual RA and there is an entry in dot11WEPEKeyMappings
            matching the MPDU's TA) then
            if that entry has WEPOn equal to false then
                discard the frame body and increment dot11WEPUndecryptableCount
            else
                if that entry contains a key that is null then
                    discard the frame body and increment dot11WEPUndecryptableCount
                else
                    WEP-decapsulate with that key, incrementing dot11WEPICVErrCount if
                    the ICV check fails
                endif
            endif
        endif
    else
        if dot11WEPDefaultKeys[Key ID] is null then
            discard the frame body and increment dot11WEPUndecryptableCount
        else
            WEP-decapsulate with dot11WEPDefaultKeys[Key ID], incrementing
            dot11WEPICVErrCount if the ICV check fails
        endif
    endif
    else
        discard the frame body and increment dot11WEPUndecryptableCount
    endif
endif

```

12.9.2 RSNA frame pseudocode

12.9.2.1 General

STAs transmit protected MSDUs, A-MSDUs, and robust Management frames to an RA when a temporal key has been configured with a MLME-SETKEYS.request primitive and an MLME-SETPROTECTION.request primitive has been invoked with ProtectType parameter Tx or Rx_Tx to that RA. STAs expect to receive protected MSDUs, A-MSDUs, and robust Management frames from a TA when a temporal key has been configured with a MLME-SETKEYS.request primitive and an MLME-SETPROTECTION.request primitive has been invoked with ProtectType parameter Rx or Rx_Tx from that TA. MSDUs, A-MSDUs, and robust Management frames that do not match these conditions are sent in the clear and are received in the clear.

12.9.2.2 Per-MSDU/Per-A-MSDU Tx pseudocode

```

if dot11RSNAActivated = true then
    if MSDU or A-MSDU has an individual RA and Protection for RA is off for Tx then
        transmit the MSDU or A-MSDU without protections
    else if (MPDU has individual RA and Pairwise key exists for the MPDU's RA) or (MPDU has
        a group addressed RA and network type is IBSS/PBSS and IBSS/PBSS GTK exists for
        MPDU's TA) then
            // If we find a suitable Pairwise or GTK for the mode we are in...

```

```

if key is a null key then
    discard the entire MSDU or A-MSDU and generate one or more MA-UNITDATA-
        STATUS.indication primitives to notify LLC that the MSDUs were undeliverable
        due to a null key
else
    // Note that it is assumed that no entry in the key
    // mapping table is of an unsupported cipher type
    Set the Key ID subfield of the IV field to 0.
    if cipher type of entry is AES-CCM then
        Transmit the MSDU or A-MSDU, to be protected after fragmentation using
        AES-CCM
    else if cipher type of entry is AES-GCM then
        Transmit the MSDU or A-MSDU, to be protected after fragmentation using
        AES-GCM
    else if cipher type of entry is TKIP then
        Compute MIC using michael algorithm and entry's Tx MIC key.
        Append MIC to MSDU
        Transmit the MSDU, to be protected with TKIP
    else if cipher type of entry is WEP then
        Transmit the MSDU, to be protected with WEP
    endif
endif
else // Else we did not find a key but we are protected, so handle the default key case or discard
    if GTK entry for Key ID contains null then
        discard the MSDU or A-MSDU and generate one or more MA-UNITDATA-
            STATUS.indication primitives to notify the LLC that the MSDUs were
            undeliverable due to a null GTK
    else if GTK entry for Key ID is not null then
        Set the Key ID subfield of the IV field to the Key ID.
        if MPDU has an individual RA and cipher type of entry is not TKIP then
            discard the entire MSDU or A-MSDU and generate one or more MA-
                UNITDATA-STATUS.indication primitives to notify the LLC that the
                MSDUs were undeliverable due to a null key
        else if cipher type of entry is AES-CCM then
            Transmit the MSDU or A-MSDU, to be protected after fragmentation using
            AES-CCM
        else if cipher type of entry is AES-GCM then
            Transmit the MSDU or A-MSDU, to be protected after fragmentation using
            AES-GCM
        else if cipher type of entry is TKIP then
            Compute MIC using michael algorithm and entry's Tx MIC key.
            Append MIC to MSDU
            Transmit the MSDU, to be protected with TKIP
        else if cipher type of entry is WEP then
            Transmit the MSDU, to be protected with WEP
        endif
    endif
endif
endif

```

12.9.2.3 Per-MMPDU Tx pseudocode

```
if ((dot11RSNAActivated = true) and (frame is a robust Management frame)) then
```

```
if ((dot11RSNAProtectedManagementFramesActivated = false) then
    Transmit the MMPDU without protection
else // dot11RSNAProtectedManagementFramesActivated = true
    if (dot11RSNAUnprotectedManagementFramesAllowed = true) then
        if (MMPDU has an individual RA) then
            if (peer STA advertised MFPC = 1) then
                if (Pairwise key exists for the MMPDU's RA) then
                    // Note that it is assumed that no entry in the key
                    // mapping table is of an unsupported cipher.
                    Transmit the MMPDU, to be protected after fragmentation
                    // see 12.9.2.5
                else if (robust Action frame) then
                    // pairwise key was not found
                    Discard the MMPDU and generate an MLME.confirm primitive to
                    notify the SME that the MMPDU was not delivered
                else // Disassociation or Deauthentication
                    Transmit the MMPDU without protection
                endif
            else // (peer STA didn't advertised MFPC = 1)
                Transmit the MMPDU without protection
            endif
        else // MMPDU has a group RA
            if (IGTK exists) then
                // if we find a suitable IGTK
                Transmit the MMPDU with protection
                // See 12.9.2.5
            else if (MMPDU is Disassociate ||Deauthenticate ||(not a robust Action frame))
            then
                Transmit the MMPDU without protection
            else
                Discard the MMPDU and generate an MLME.confirm primitive to notify
                the SME that the MMPDU was undeliverable
            endif
        endif
    else // dot11RSNAUnprotectedManagementFramesAllowed = false
        if (MMPDU has an individual RA) then
            if (peer STA advertised MFPC = 1) then
                if (Pairwise key exists for the MMPDU's RA) then
                    // Note that it is assumed that no entry in the key
                    // mapping table is of an unsupported cipher.
                    Transmit the MMPDU, to be protected after fragmentation
                    // see 12.9.2.5
                else if (robust Action frame) then
                    // pairwise key was not found
```

Discard the MMPDU and generate an MLME.confirm primitive to notify the SME that the MMPDU was not delivered

else // FrameControlSubType is Disassociation or Deauthentication
 Transmit the MMPDU without protection
endif

else // peer STA didn't advertise MFPC = 1
 Discard the MMPDU and generate an MLME.confirm primitive to notify the SME that the MMPDU was not delivered
endif

else // MMPDU has a group RA
 if (IGTK exists) **then**
 // if we find a suitable IGTK
 Transmit the MMPDU with protection
 // See 12.9.2.5
 else if (MMPDU is Disassociate || Deauthenticate || (not a robust Action frame))
 then
 Transmit the MMPDU without protection
 else
 Discard the MMPDU and generate an MLME.confirm primitive to notify the SME that the MMPDU was undeliverable
 endif
 endif
 endif

else // (dot1IRSNAActivated = false) **or** (not a robust Management frame)
 Use 12.9.2.2 to transmit the frame
endif

12.9.2.4 Per-MPDU Tx pseudocode

12.10 Authenticated mesh peering exchange (AMPE)

The authenticated mesh peering exchange is defined in 14.5.

12.11 AP PeerKey support

12.11.1 AP PeerKey overview

The AP PeerKey protocol provides session identification and creation of an AP PeerKey association to provide for security of OBSS management communication between two APs. The result of a successful run of the AP PeerKey protocol is an AP PeerKey association. An AP PeerKey association is composed of a mesh PMKSA and a mesh TKSA.

Two APs perform the AP PeerKey protocol in order to protect HCCA TXOP Advertisement frames in an OBSS. The AP PeerKey protocol is unauthenticated (neither peer has a verified identity of the other peer) but an AP knows that only the peer AP that completed the AP PeerKey protocol is able to send protected HCCA TXOP Advertisement frames protected by the resulting AP PeerKey association. This allows an AP to determine whether a peer AP honors the HCCA TXOP avoidance schedule that is negotiated. In this manner, an AP is able to honor the negotiated schedule of trusted peer APs and ignore peer APs that are not trustworthy. This allows trustworthy APs to negotiate mutually beneficial schedules while allowing an AP to not disadvantage itself in an OBSS in the presence of untrustworthy APs.

AP PeerKey uses various functions and data to accomplish its task and assumes certain properties about each function as follows:

- H is an “extractor” function (see IETF RFC 5869) that concentrates potentially dispersed entropy from an input to create an output that is a cryptographically strong, pseudorandom key. This function takes as input a non-secret “salt” and a secret input and produces a fixed-length output.
- A finite cyclic group is negotiated for which solving the discrete logarithm problem is computationally infeasible.

When using AKM suite selector 00-0F-AC:10 to indicate AP PeerKey, H shall be instantiated as HMAC-SHA-256, taking as input a non-secret “salt” and a secret input keying material “ikm”:

$$H(\text{salt}, \text{ikm}) = \text{HMAC-SHA-256}(\text{salt}, \text{ikm})$$

Other instantiations of function H require creation of a new AKM identifier.

12.11.2 AP PeerKey protocol

AP PeerKey uses the same discrete logarithm cryptography as SAE (as described in 12.4) to achieve key agreement. Each party to the exchange has a public and private key with respect to a particular set of domain parameters that define a finite cyclic group. Groups may be based on elliptic curve cryptography (ECC) or finite field cryptography (FFC). Each component of a group is referred to as an *element*. Groups are negotiated using an identifying number from a repository maintained by IANA as “Group Description” attributes for IETF RFC 2409 (IKE) [B17][B31]. The repository maps an identifying number to a complete set of domain parameters for the particular group. For the purpose of interoperability, APs that have dot11ProtectedHCCATXOPNegotiationImplemented true or dot11ProtectedQLoadReportImplemented true shall support group 19, an ECC group defined over a 256-bit prime order field.

AP PeerKey uses one arithmetic operator that takes one element and one scalar value to produce another element (called the *scalar operation*). The convention used here is to represent group elements in uppercase bold italic and scalar values in lowercase italic. The scalar operation takes an element and a scalar and is denoted $\text{scalar-op}(x, Y)$.

The private key d shall be chosen randomly so that $1 < d < r$, where r is the order of the group. The public key \mathbf{Q} shall be produced using Equation (12-1).

$$\mathbf{Q} = \text{scalar-op}(d, \mathbf{G}) \quad (12-1)$$

where

\mathbf{G} is the generator (also known as the base point) of the group

An AP for which dot11ProtectedTXOPNegotiationActivated is true or dot11ProtectedQLoadReportActivated is true shall support at least one public key from cyclic group nineteen and may support multiple public keys from multiple cyclic groups. An AP that supports the Multiple BSSID capability and has dot11ProtectedTXOPNegotiationActivated true or dot11ProtectedQLoadReportActivated true may use one public key across multiple BSSIDs, or it may choose to generate a public key for each supported BSSID.

The AP PeerKey protocol consists of an exchange of public keys from an AP and a peer AP. An AP requests the public key of a peer AP by sending a Public Key frame with the Public Key Frame Usage field set to “Request.” This frame contains the public key of the initiating AP. The initiating AP awaits a response to its request. The peer AP responds to the “Request” from the initiating AP with a Public Key frame with the Public Key Frame Usage field set to “Response”, indicating an acceptable group was sent by the initiating AP, or set to “NAK” indicating that the group sent by the initiating AP was unacceptable.

It is possible for multiple runs of the AP PeerKey protocol to be performed by an AP but there shall be only one instance at a time of the AP PeerKey protocol to a peer AP for a particular group. The state associated with each run of the AP PeerKey protocol is the group and the two public keys of the participating APs.

An AP for which dot11ProtectedTXOPNegotiationActivated is true or dot11ProtectedQLoadReportActivated is true shall reply to a Public Key frame. An AP that has both dot11ProtectedTXOPNegotiationActivated is false and dot11ProtectedQLoadReportActivated is false shall drop all received Public Key frames. If the responding AP refuses to perform the AP PeerKey protocol with the initiating AP it shall respond with a Public Key frame, setting the Public Key Frame Usage field to “Refused”. Otherwise, if the Group field in the public key request is a group that is supported by the responding AP, the AP shall reply with a public key of the same group as the request, generating such a key pair if required, and setting the Public Key Frame Usage field to “Response”. The receiving AP shall

generate a PMK and a mesh PMKSA, see below, and terminate the PeerKey protocol. If the group field in the public key request is not supported by the responding AP, the responding AP shall respond with a Public Key frame, setting the Public Key Frame Usage field to “NAK” and the group set to a group acceptable by the receiving AP.

If the initiating AP does not receive a response to its request after five seconds, it should retransmit its request. The initiating AP should attempt such retransmission a minimum of five times.

If the initiating AP receives a Public Key frame from a peer AP with the Public Key Frame Usage field set to “NAK”, the initiating AP inspects the group field in the received “NAK”. If the group is supported, the initiating AP should initiate to the peer AP using the indicated group. If the group is not supported, the AP may choose to initiate to the peer AP using a different group from the dot11RSNAConfigDLCGroup table. Receipt of a Public Key frame from a peer AP with the Public Key Frame Usage field set to “NAK” terminates the PeerKey protocol.

If the initiating AP receives a Public Key frame from a peer AP with the Public Key Frame Usage field set to “Refused”, the initiating AP shall terminate the PeerKey protocol.

An initiating AP that receives a refusal should delay sending another request for at least 5 seconds, and should perform exponential back-off on all subsequent requests by doubling the delay with each subsequent refusal.

NOTE—This standard does not specify a limit on the number of attempts an initiating AP makes to communicate with another AP.

If the initiating AP receives a Public Key frame from a peer AP with the Public Key Frame Usage field set to “Response” and the group set to the value in the initiating AP’s “Request”, the initiating AP shall generate a PMK and a mesh PMKSA. This terminates the PeerKey protocol.

If the initiating AP receives a Public Key frame from a peer AP with the Public Key Frame Usage field set to “Request” prior to receiving a “Response”, it checks the Group field in the request. If the Group in the received “Request” is the same as the Group the initiating AP sent in its request, the AP shall construct a Public Key frame with the Public Key Frame Usage field set to “Response” containing the public key it sent in its “Request” and transmit it to the peer. The AP shall then generate a PMK and a mesh PMKSA, see below, and terminate the PeerKey protocol. If the Group field differs and the group indicated is supported, the AP shall respond to the peer AP by replying with a public key from that group, generating a key pair if required, and setting the Public Key Frame Usage field to “Response”. The AP shall generate a PMK and a mesh PMKSA, see below, and terminate this run of the PeerKey protocol.

Once the AP and peer AP have exchanged public keys from the same finite cyclic group they can compute the Diffie-Hellman shared secret using scalar-op() and function F from 12.4.4:

$$k = F(\text{scalar-op}(d, Q_p)) \quad (12-2)$$

where

- d is the private key of the AP that is calculating k
- Q_p is the public key of the peer AP

Entropy of the shared secret shall then be extracted using function H to produce *keyseed* using Equation (12-3).

$$\text{keyseed} = H(<0>32, k) \quad (12-3)$$

where

<0>32 denotes 32 octets of the value zero

The PMK shall be derived according to Equation (12-4), and the PMKID shall be derived according to Equation (12-5).

$$\text{PMK} = \text{KDF-Hash-256}(\text{keyseed}, \text{"AP Peerkey Protocol"}, \\ 0x00 \parallel \text{Max(LOCAL-MAC, PEER-MAC)} \parallel \text{Min(LOCAL-MAC, PEER-MAC)}) \quad (12-4)$$

$$\text{PMKID} = \text{Truncate-128}(\text{SHA-256}(Q_1 \parallel Q_2 \parallel \\ \text{Max(LOCAL-MAC, PEER-MAC)} \parallel \\ \text{Min(LOCAL-MAC, PEER-MAC)})) \quad (12-5)$$

where

KDF-Hash-256 is the key derivation function defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133)

0x00 is a single octet with a value of zero

LOCAL-MAC is the AP's MAC address

PEER-MAC is the peer AP's MAC address

Q_1 is the public key used by AP1 in the AP PeerKey protocol encoded as an octet stream using the Element to Octet string conversion from 12.4.7.2.3.

Q_2 is the public key used by AP2 in the AP PeerKey protocol encoded as an octet stream using the Element to Octet string conversion from 12.4.7.2.3.

AP1 is the AP whose MAC address equals Max(LOCAL-MAC, PEER-MAC)

AP2 is the AP whose MAC address equals Min(LOCAL-MAC, PEER-MAC)

The Max and Min operations for IEEE 802 addresses are with the address converted to a positive integer treating the first octet as the most significant octet of the integer.

keyseed shall be irretrievably deleted after the PMK is generated.

The lifetime of the mesh PMKSA shall be set to the value dot11RSNAConfigPMKLifetime.

Upon creation of the PMK, an AEK shall be created per 14.5.7. The mesh PMKSA for this instance of the AP PeerKey protocol shall then be created using the AP's MAC address as the STA's MAC address, the peer AP's MAC address as the peer STA's MAC address, the AEK, the lifetime, and the PMKID. If a mesh PMKSA created by a prior run of the AP PeerKey protocol exists it shall be deleted upon creation of the new PMKSA. All mesh TKSAAs created by the old mesh PMKSA shall also be deleted.

Upon creation of the mesh PMKSA, the APME protocol (as defined in 14.5) shall be used to prove possession of the PMK (and implicitly the private key that corresponds to the peer's public key) and generate the mesh TKSA.

Note that it is possible for two APs which simultaneously initiated to each other with different, but acceptable, groups to end up with two mesh PMKSAs. In this unlikely case, the mesh PMKSA from a group with the largest prime in its domain parameter set shall be used with the AMPE protocol. The other mesh PMKSA shall be deleted.

If the AMPE protocol completes successfully, Protected HCCA TXOP Advertisement frames and Protected HCCA TXOP Response frames may be used in the HCCA TXOP negotiation procedures, as defined in 11.28.3 using the MTK from the mesh TKSA. If the AMPE procedure completes successfully, Protected QLoad Request frames and Protected QLoad Report frames may be used in the QLoad report procedures, as defined in 11.28.2 using the MTK from the mesh TKSA. If the AMPE protocol fails, the peer's public key, PMK, and PMKSA shall be deleted.

NOTE—The PMK, as well as any key derived from it, is not authenticated in any way nor is it bound to any identity. This protocol protects an AP that cooperates in scheduling its HCCA TXOPs using Protected HCCA TXOP Advertisement frames because no other entity knows its private key and cannot forge Protected HCCA TXOP Advertisement frames. An AP that receives a Protected HCCA TXOP Advertisement frame is assured it was sent by the holder of a particular private key, and no one else, and can, therefore, establish which APs are cooperating in their HCCA TXOP scheduling. An AP that receives a Protected QLoad Report frame is assured it was sent by the holder of a particular private key, and no other STA, and can, therefore, establish which APs are correctly reporting their QoS load.

13. Fast BSS transition

13.1 Overview

Fast BSS transition seeks to reduce the length of time that connectivity is lost between a STA and the DS during a BSS transition. The FT protocols are part of the reassociation service and only apply to STA transitions between APs within the same mobility domain within the same ESS.

The FT protocols require information to be exchanged during the initial association (or a later reassociation) between a STA (known as the *FT Originator* (FTO)) and AP. The initial exchange is referred to as the *FT initial mobility domain association*. Subsequent reassociations to APs within the same mobility domain may make use of the FT protocols.

Two FT protocols are defined:

- *FT protocol*. This protocol is executed when an FTO makes a transition to a target AP and does not require a resource request prior to its transition.
- *FT resource request protocol*. This protocol is executed when an FTO requires a resource request prior to its transition.

For an FTO to move from its current AP to a target AP utilizing the FT protocols, the message exchanges are performed using one of two methods:

- *Over-the-Air*. The FTO communicates directly with the target AP using IEEE 802.11 authentication with the FT authentication algorithm.
- *Over-the-DS*. The FTO communicates with the target AP via the current AP. The communication between the FTO and the target AP is carried in FT Action frames between the FTO and the current AP. Between the current AP and target AP, communication is via an encapsulation method described in 13.10.3. The current AP converts between the two encapsulations.

APs advertise both capabilities and policies for supporting the FT protocols and methods.

Throughout this clause, the notation *Authentication-Request* refers to an Authentication frame with the Authentication Transaction Sequence Number field equal to 1; *Authentication-Response* refers to an Authentication frame with the Authentication Transaction Sequence Number field equal to 2; *Authentication-Confirm* refers to an Authentication frame with the Authentication Transaction Sequence Number field equal to 3; *Authentication-Ack* refers to an Authentication frame with the Authentication Transaction Sequence Number field equal to 4. The first parameter to the above four messages is the authentication algorithm, such as Open System authentication algorithm (i.e., *Open* in figures in this clause) or FT authentication algorithm (i.e., *FTAA* in figures in this clause).

13.2 Key holders

13.2.1 Introduction

The FT key holder architecture, shown in Figure 13-1, describes the FT key management entities and is defined in the context of the IEEE 802.11 basic reference model (see Figure 4-19 in 4.9).

The R0KH and R1KH are part of AP's SME RSNA key management. The computation of PMK-R0 and PMK-R1, and all of the intermediate results in the computations, shall be restricted to the R0KH. The computation of PTK, and all intermediate results in its computation, shall be restricted to the R1KH.

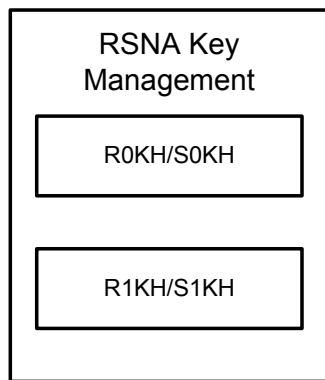

Figure 13-1—FT key holder architecture

The S0KH and S1KH are part of the FTO's SME RSNA key management. The computation of PMK-R0 and PMK-R1, and all of the intermediate results in the computations, shall be restricted to the S0KH. The computation of PTK, and all intermediate results in its computation, shall be restricted to the S1KH.

13.2.2 Authenticator key holders

The R0KH and R1KH are responsible for the derivation of keys in the FT key hierarchy. For fast BSS transition, the functions of the IEEE 802.1X Authenticator are distributed among the R0KH and R1KHS.

The R0KH interacts with the IEEE 802.1X Authenticator to receive the MSK resulting from an EAP authentication. The R1KH interacts with the IEEE 802.1X Authenticator to open the Controlled Port. Both the R0KH and R1KH interactions with the IEEE 802.1X Authenticator occur within the SME.

The R0KH derives the PMK-R0 for use in the mobility domain utilizing the MSK (when the AKM negotiated is 00-0F-AC:3), the PSK (when the AKM negotiated is 00-0F-AC:4) or the PMK (when the AKM negotiated is 00-0F-AC:9). The R0KH shall be responsible for deriving a PMK-R1 for each R1KH within the mobility domain.

The R1KH and S1KH each derive the PTK.

Each R0KH-ID and R1KH-ID is assumed to be expressed as a unique identifier within the mobility domain. This identifier is communicated to the FTO and other key holders. The R0KH-ID is bound into the PMK-R0 derivation and the R1KH-ID is bound into the PMK-R1 derivation.

The R0KH shall meet the following requirements:

- The R0KH shall be collocated with the network access server (NAS) Client functionality of the IEEE 802.1X Authenticator.
- The R0KH-ID shall be set to the identity of the co-resident NAS Client (e.g., NAS-Identifier as defined in IETF RFC 2865 if RADIUS is used as the backend protocol). R0KH-ID shall not be longer than 48 octets to fit in the length limitation of the FTE.
- When the PMK-R0 lifetime expires, the R0KH shall delete the PMK-R0 security association and shall revoke within the R0KH all PMK-R1s derived from the PMK-R0.
- The R0KH shall not expose the PMK-R0 to other parties.
- The R0KH shall not expose the PMK-R1 to parties other than the authorized R1KH.

The R1KH shall meet the following requirements:

- The R1KH-ID shall be set to a MAC address of the physical entity that stores the PMK-R1 and uses it to generate the PTK. That same MAC address shall be used to advertise the PMK-R1 identity to the STA and the R0KH.
- The R1KH shall derive and distribute the GTK and IGTK to all connected STAs.
- When the PMK-R1 lifetime expires, the R1KH shall delete the PMK-R1 PMKSA and shall revoke all PTKSAs derived from the PMK-R1 using the MLME-DELETEKEYS primitive.
- The R1KH shall not expose the PMK-R1 to other parties.

dot11FTR0KeyHolderID and dot11FTR1KeyHolderID shall contain the values of R0KH-ID and R1KH-ID as defined in this clause, respectively.

The R0KH and the R1KH are assumed to have a secure channel between them that can be used to exchange cryptographic keys without exposure to any intermediate parties. The cryptographic strength of the secure channel between the R0KH and R1KH is assumed to be greater than or equal to the cryptographic strength of the channels for which the keys are used. This standard assumes that the key transfer includes the PMK-R1, the PMK-R1 PMKSA, the PMK-R1 context, and the associated key authorizations. The protocol for distribution of keying material from the R0KH to the R1KH is outside the scope of this standard.

The PMK-R1 distribution from the R0KH to the R1KHS within the same mobility domain shall satisfy the following assumptions:

- The R0KH authenticates a potential R1KH with the same identity as is included in the PMK-R1 derivation. The cryptographic strength of the authentication is assumed to be greater than or equal to the cryptographic strength of the authentication between the Supplicant and AS.
- The authorization of holding a PMK-R1 is based on the authentication of the R1KH.
- The protected channel provides confidentiality and integrity protection.

13.2.3 Supplicant key holders

The S0KH and S1KH are responsible for the derivation of keys in the FT key hierarchy. The S0KH and S1KH are entities that are assumed to physically reside in the Supplicant.

The S0KH interacts with the IEEE 802.1X functional block (see Figure 4-19 in 4.9) to receive the MSK resulting from an EAP authentication. The S1KH interacts with the IEEE 802.1X entity to open the Controlled Port. Both the S0KH and S1KH interactions with the IEEE 802.1X entity occur within the SME of a STA.

The S0KH derives the PMK-R0 for use in the mobility domain utilizing the MSK (when the AKM negotiated is 00-0F-AC:3), the PSK (when the AKM negotiated is 00-0F-AC:4) or the PMK (when the AKM negotiated is 00-0F-AC:9).

The S1KH shall derive the PTK mutually with the R1KH.

The S0KH and S1KH shall be identified by the SPA. The S0KH shall not expose the PMK-R0 to other parties and shall not expose the PMK-R1 to parties other than the authorized S1KH. The S1KH shall not expose the PMK-R1 to other parties.

13.3 Capability and policy advertisement

The FT capability is advertised in the Beacon and Probe Response frames by including the MDE. The MDE is advertised in the Beacon and Probe Response frames to indicate the MDID, FT capability, and the FT policy.

The MDID field shall be dot11FTMobilityDomainID. The Fast BSS Transition Policy bits in the MDE, i.e., Fast BSS Transition over DS subfield and Resource Request Protocol Capability subfield, shall be set by dot11FTOverDSActivated and dot11FTResourceRequestSupported, respectively.

NOTE—It is assumed by this standard that the Fast BSS Transition Policy bits in the MDE are administered consistently across the mobility domain.

The capability is advertised in the Neighbor Report element. See 11.11 and 9.4.2.37.

If an FTE is included in a Request element in a Probe Request frame, the FTE in the Probe Response frame shall contain the R0KH-ID and R1KH-ID (from dot11FTR0KeyHolderID and dot11FTR1KeyHolderID), and all other fields shall be set to 0.

13.4 FT initial mobility domain association

13.4.1 Overview

The FT initial mobility domain association is the first (re)association in the mobility domain, where the SME of the STA enables its future use of the FT procedures.

FT initial mobility domain association is typically the first association within the ESS. In addition to Association frames, Reassociation frames are supported in the initial mobility domain association to enable both FT and non-FT APs to be present in a single ESS.

13.4.2 FT initial mobility domain association in an RSN

A STA indicates its support for the FT procedures by including the MDE in the (Re)Association Request frame and indicates its support of security by including the RSNE. The AP responds by including the FTE, MDE, and RSNE in the (Re)Association Response frame. After a successful IEEE 802.1X authentication (if needed) or SAE authentication, the STA and AP perform an FT 4-way handshake. At the end of the sequence, the IEEE 802.1X Controlled Port is opened, and the FT key hierarchy has been established. The message flow is shown in Figure 13-2.

A non-DMG STA initiates the FT initial mobility domain association procedures by performing an IEEE 802.11 authentication using the Open System authentication algorithm.

STA→AP: Authentication-Request (Open System authentication algorithm)
AP→STA: Authentication-Response (Open System authentication algorithm, Status)

A DMG STA initiates the FT initial mobility domain association procedures by performing an IEEE 802.11 authentication using the SAE algorithm.

STA→AP: Authentication-Request (SAE algorithm)
AP→STA: Authentication-Response (SAE algorithm, Status)

The SME of the STA initiates the authentication exchange, through the use of the MLME-AUTHENTICATE.request primitive, and the SME of the AP responds with MLME-AUTHENTICATE.response primitive. See 11.3.4.

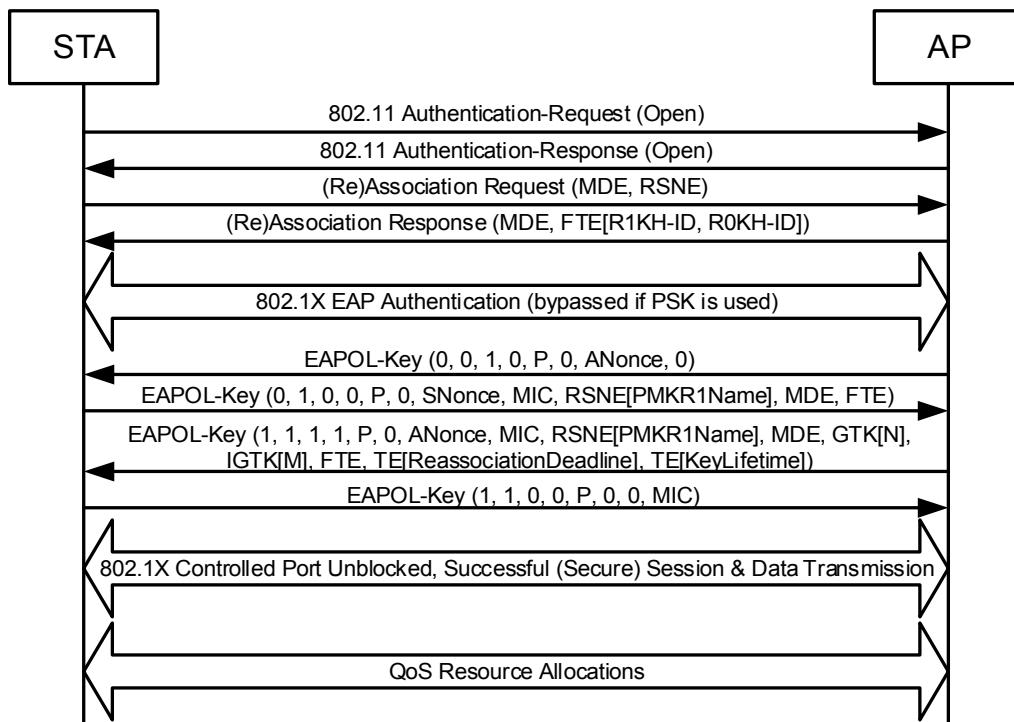

Figure 13-2—FT initial mobility domain association in an RSN

Upon successful IEEE 802.11 Open System authentication, (if the suite type is 00-0F-AC:3 or 00-0F-AC:4) or SAE authentication (if the suite type is 00-0F-AC:9), the STA shall send a (Re)Association Request frame to the AP that includes the MDE. The contents of the MDE shall be the values advertised by the AP in its Beacon or Probe Response frames. Additionally, the STA includes its security capabilities in the RSNE.

STA→AP: (Re)Association Request (MDE, RSNE)

AP→STA: (Re)Association Response (MDE, FTE[R1KH-ID, R0KH-ID])

The SME of the STA initiates the (re)association through the use of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive. The SME of the AP responds to the indication with MLME-ASSOCIATE.response or MLME-REASSOCIATE.response primitive. See 11.3.5.

If the contents of the MDE received by the AP do not match the contents advertised in the Beacon and Probe Response frames, the AP shall reject the (Re)Association Request frame with status code STATUS_INVALID_MDE. If an MDE is present in the (Re)Association Request frame and the contents of the RSNE do not indicate a negotiated AKM of fast BSS transition (suite type 00-0F-AC:3, 00-0F-AC:4, or 00-0F-AC:9), the AP shall reject the (Re)Association Request frame with status code STATUS_INVALID_AKMP.

The (Re)Association Response frame from the AP shall contain an MDE, with contents as presented in Beacon and Probe Response frames. The FTE shall include the key holder identities of the AP, the R0KH-ID and R1KH-ID, set to the values of dot11FTR0KeyHolderID and dot11FTR1KeyHolderID, respectively. The FTE shall have a MIC element count of zero (i.e., no MIC present) and have ANonce, SNonce, and MIC fields set to 0.

On successful (re)association, the S0KH on the STA and the R0KH on the AP then proceed with an IEEE 802.1X authentication using EAPOL frames carried in IEEE 802.11 Data frames if SAE authentication was not performed (i.e., if the suite type is not 00-0F-AC:9). The S0KH shall use the value of

R0KH-ID as the endpoint identifier of the NAS Client (NAS-Identifier if RADIUS is used) in the exchange as defined in IETF RFC 3748 [B42].

If IEEE 802.1X authentication was performed, then upon successful completion of authentication, the R0KH receives the MSK and authorization attributes. If SAE authentication was performed, the R0KH receives the PMK, resulting in the successful completion of SAE. If a key hierarchy already exists for this STA belonging to the same mobility domain (i.e., having the same MDID), the R0KH shall delete the existing PMK-R0 security association and PMK-R1 security associations. It then calculates the PMK-R0, PMK-R0Name, and PMK-R1 and makes the PMK-R1 available to the R1KH of the AP with which the STA is associated.

If the SME of the STA cannot authenticate the AS, then it shall disassociate with an MLME-DISASSOCIATE.request primitive. If the AS signals the Authenticator that the STA cannot be authenticated, then the SME of the AP shall disassociate with an MLME-DISASSOCIATE.request primitive.

If the MSK lifetime attribute is provided by the AS, the lifetime of the PMK-R0 shall not be more than the lifetime of the MSK. If the MSK lifetime attribute is not provided, the PMK-R0 lifetime shall be dot11FTR0KeyLifetime. For PSK, the PMK-R0 lifetime shall be dot11FTR0KeyLifetime. The lifetime of the PMK-R1s and PTK shall be the same as the lifetime of PMK-R0. When the key lifetime expires, each key holder shall delete its respective PMK-R0, PMK-R1, and PTK SAs.

The R1KH and S1KH then perform an FT 4-way handshake. The EAPOL-Key frame notation is defined in 12.7.4.

R1KH→S1KH: EAPOL-Key(0, 0, 1, 0, P, 0, 0, ANonce, 0)
S1KH→R1KH: EAPOL-Key(0, 1, 0, 0, P, 0, 0, SNonce, MIC, RSNE[PMKR1Name], MDE, FTE)
R1KH→S1KH: EAPOL-Key(1, 1, 1, 1, P, 0, 0, ANonce, MIC, RSNE[PMKR1Name], MDE,
 GTK[N], IGTK[M], FTE, TIE[ReassociationDeadline],
 TIE[KeyLifetime])
S1KH→R1KH: EAPOL-Key(1, 1, 0, 0, P, 0, 0, 0, MIC)

The message sequence is described in 12.7.6.

It is assumed by this standard that the reassociation deadline is administered consistently across the mobility domain. The mechanism for such consistent administration is outside the scope of this standard.

The PTK shall be calculated by the R1KH and S1KH according to the procedures given in 12.7.1.7.5.

Upon completion of a successful FT 4-way handshake, the IEEE 802.1X Controlled Port shall be opened on both the non-AP STA and the AP. Subsequent EAPOL-Key frames shall use the key replay counter to detect replayed messages.

Upon completion of a successful FT 4-way handshake, the PTK lifetime timer is initiated. The operation of this timer prevent the PTKSA being used for longer than the value provided in the TIE[KeyLifetime] sent in message 3.

Once the PTKSA key lifetime expires, as indicated by the TIE[KeyLifetime], to continue its association in the mobility domain the STA shall perform the FT initial mobility domain association procedures. If the AP sends a Deauthentication or Disassociation frame to the STA with reason code INVALID_AUTHENTICATION, then to continue its association in the mobility domain, the STA shall perform the FT initial mobility domain association procedures with any AP in the mobility domain. If the Suplicant EAPOL state machines are triggered to send an EAPOL-Start frame after a successful initial mobility domain association, the STA shall perform the FT initial mobility domain association procedures.

13.4.3 FT initial mobility domain association in a non-RSN

In this sequence, the STA utilizes the FT procedures by including the MDE in the (Re)Association Request frame. The AP responds by including the MDE in the (Re)Association Response frame. The message flow is shown in Figure 13-3.

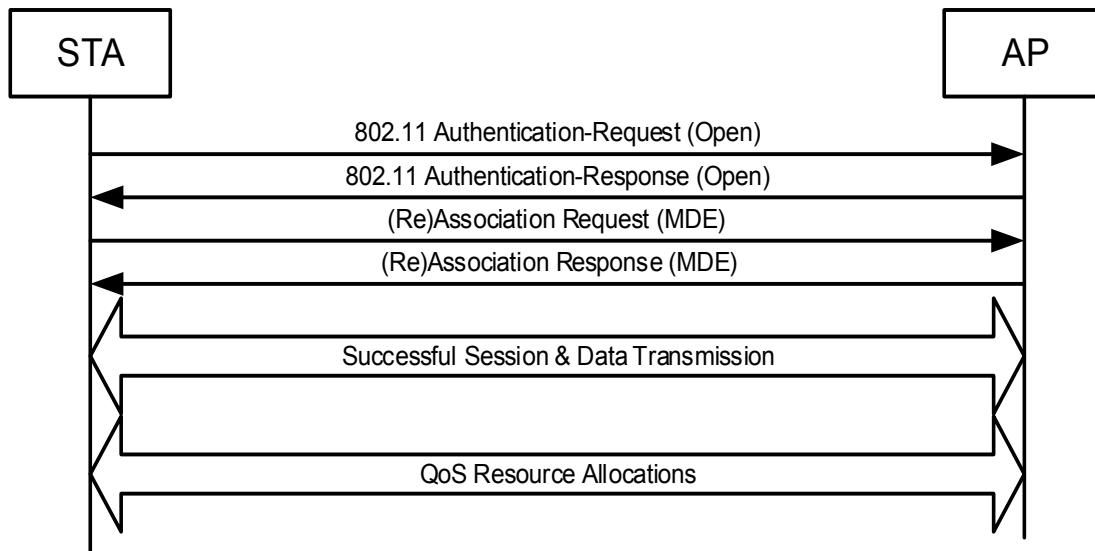

Figure 13-3—FT initial mobility domain association in a non-RSN

The STA initiates the FT initial mobility domain association procedures by performing an IEEE 802.11 authentication using the Open System authentication algorithm.

STA→AP: Authentication-Request (Open System authentication algorithm)

AP→STA: Authentication-Response (Open System authentication algorithm, Status)

The SME of the STA initiates the authentication exchange through the use of the primitive MLME-AUTHENTICATE.request primitive, and the SME of the AP responds with MLME-AUTHENTICATE.response primitive. See 11.3.4.

Upon successful IEEE 802.11 Open System authentication, the STA shall send a (Re)Association Request frame to the AP and shall include the MDE. The contents of the MDE shall be the values advertised by the AP in its Beacon or Probe Response frames.

STA→AP: (Re)Association Request (MDE)

AP→STA: (Re)Association Response (MDE)

The SME of the STA initiates the (re)association through the use of the MLME-ASSOCIATE.request or MLME-REASSOCIATE.request primitive. The SME of the AP responds to the indication with MLME-ASSOCIATE.response or MLME-REASSOCIATE.response primitive. See 11.3.5.

If the contents of the MDE received by the AP do not match the contents advertised in the Beacon and Probe Response frames, the AP shall reject the (Re)Association Request frame with status code STATUS_INVALID_MDE.

The (Re)Association Response frame from the AP shall contain an MDE, with contents as presented in Beacon and Probe Response frames.

On successful (re)association, the AP and the non-AP STA shall transition to State 4 (as defined in 11.3) to enable Data frame transmission.

13.5 FT protocol

13.5.1 Overview

STAs with dot11FastBSSTransitionActivated equal to true shall support the FT protocol.

The FT protocol supports resource requests as part of the reassociation. The optional FT resource request protocol (see 13.6) supports resource requests prior to reassociation.

A STA shall not use any authentication algorithm except the FT authentication algorithm when using the FT protocol.

13.5.2 Over-the-air FT protocol authentication in an RSN

The over-the-air FT protocol in an RSN is shown in Figure 13-4.

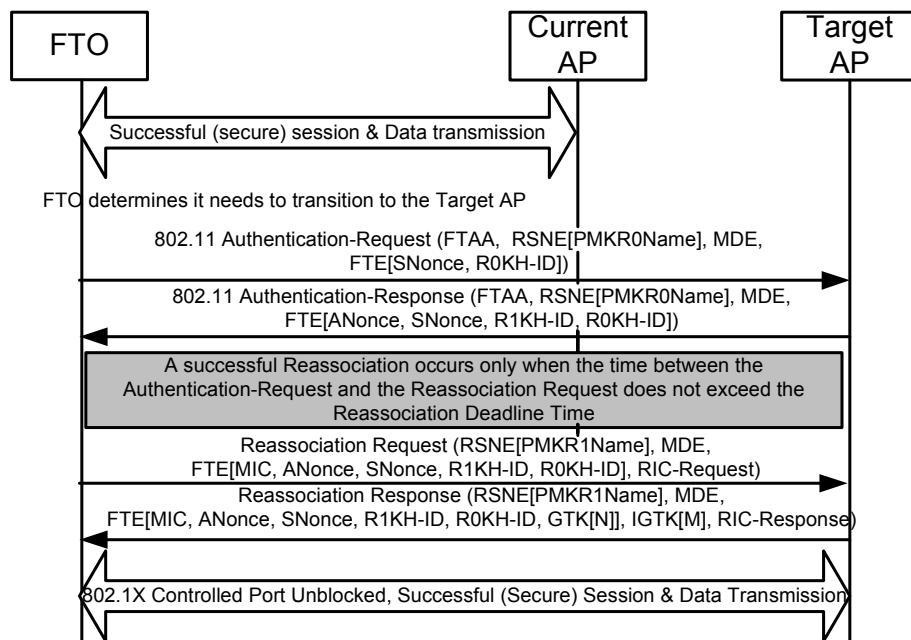

Figure 13-4—Over-the-air FT protocol in an RSN

The FTO and AP use the FT authentication sequence to specify the PMK-R1 security association and to provide values of SNonce and ANonce that enable a liveness proof, replay protection, and PTK separation. This exchange enables a fresh PTK to be computed in advance of reassociation. The PTKSA is used to protect the subsequent reassociation transaction, including the optional RIC-Request.

To perform an over-the-air fast BSS transition to a target AP, the FTO and target AP shall perform the following exchange:

FTO→Target AP: Authentication-Request (FTAA, 0, RSNE[PMKR0Name], MDE, FTE[SNonce, R0KH-ID])

Target AP→FTO: Authentication-Response (FTAA, Status, RSNE[PMKR0Name], MDE, FTE[ANonce, SNonce, R1KH-ID, R0KH-ID])

The SME of the FTO initiates the authentication exchange, through the use of the MLME-AUTHENTICATE.request primitive, and the SME of the AP responds with an MLME-AUTHENTICATE.response primitive. See 11.3.4. The MLME primitives for Authentication when the FT authentication algorithm is selected use only authentication transaction sequence number values 1 and 2.

In the Authentication-Request frame, the SA field of the message header shall be set to the MAC address of the FTO, and the DA field of the message header shall be set to the BSSID of the target AP. The elements in the frame, and their required contents, shall be as given in 13.8.2.

If the contents of the MDE received by the AP do not match the contents advertised in the Beacon and Probe Response frames, the AP shall reject the authentication request with status code STATUS_INVALID_MDE. If the Authentication-Request frame contains an authentication algorithm equal to FT authentication and the contents of the RSNE do not indicate a negotiated AKM of fast BSS transition (suite type 00-0F-AC:3 or 00-0F-AC:4), the AP shall reject the authentication request with status code STATUS_INVALID_AKMP. If the FTE in the FT Request frame contains an invalid R0KH-ID, the AP shall reject the FT Request frame with status code STATUS_INVALID_FTE. If the RSNE in the Authentication-Request frame contains an invalid PMKR0Name and the AP has determined that it is an invalid PMKR0Name, the AP shall reject the authentication request with status code STATUS_INVALID_PMKID. If the requested R0KH is not reachable, the AP shall respond to the authentication request with status code R0KH_UNREACHABLE. If the FTO selects a pairwise cipher suite in the RSNE that is different from the ones used in the Initial mobility domain association, then the AP shall reject the authentication request with status code STATUS_INVALID_PAIRWISE_CIPHER. Subsequent to a rejection of an authentication request, the FTO may retry the authentication request.

In the Authentication-Response frame, the SA field of the message header shall be set to the BSSID of the target AP, and the DA field of the message header shall be set to the MAC address of the FTO. The Status Code field shall be a value from the options listed in 9.4.1.9. The elements in the frame, and their required contents, shall be as given in 13.8.3.

The R1KH of the target AP uses the value of PMKR0Name and other information in the frame to calculate PMKR1Name. If the target AP does not have the key identified by PMKR1Name, it may retrieve that key from the R0KH identified by the FTO. See 13.2. Upon receiving a new PMK-R1 for a STA, the target AP shall delete the prior PMK-R1 security association and PTKSAs derived from the prior PMK-R1.

The FTO and the target AP compute the PTK and PTKName using the PMK-R1, PMKR1Name, ANonce, and SNonce, as specified in 12.7.1.7.5. The PTKSA shall be deleted by the target AP if it does not receive a Reassociation Request frame from the FTO within the reassociation deadline timeout value.

If the FTO does not receive a response to the Authentication-Request frame, it may reissue the request following the restrictions given for Authentication frames in 11.3. If the Status Code field value returned by the target AP is SUCCESS, the FTO and target AP transition to State 2 (as defined in 11.3); the FTO may continue with reassociation (13.7.1). Handling of errors returned in the Status Code field shall be as specified in 11.3.

13.5.3 Over-the-DS FT protocol in an RSN

A STA shall not initiate an over-the-DS FT authentication to a target AP whose MDE contains the Fast BSS Transition over DS bit equal to 0.

The over-the-DS FT protocol in an RSN is shown in Figure 13-5.

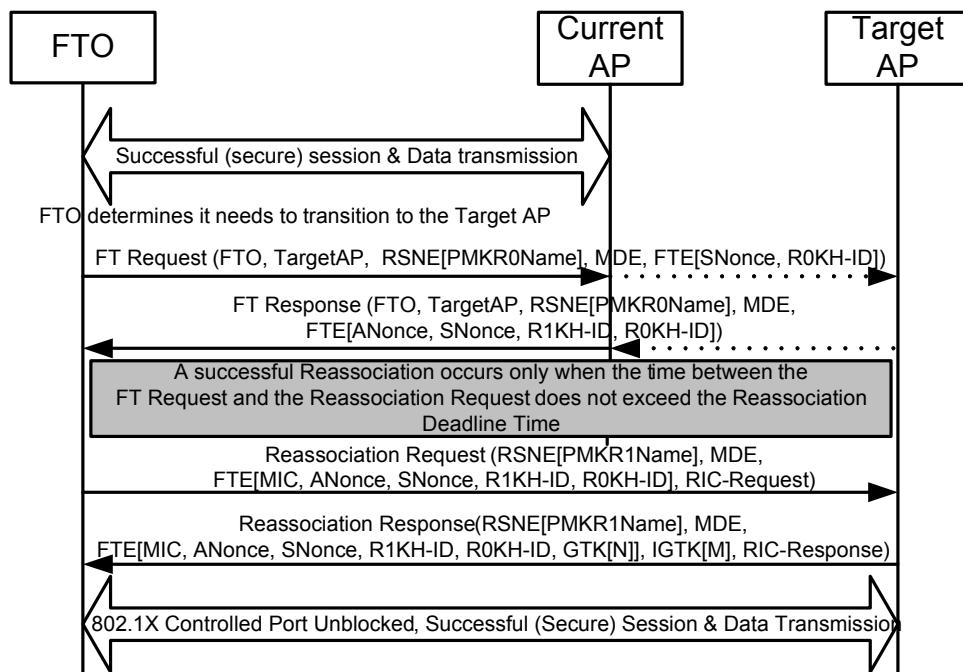

Figure 13-5—Over-the-DS FT protocol in an RSN

To perform an over-the-DS fast BSS transition to a target AP, the FTO and the target AP (through the current AP) shall perform the following exchange:

FTO→Target AP: FT Request (FTO address, TargetAP address, RSNE[PMKR0Name], MDE, FTE[SNonce, R0KH-ID])

Target AP→FTO: FT Response (FTO address, TargetAP address, Status, RSNE[PMKR0Name], MDE, FTE[ANonce, SNonce, R1KH-ID, R0KH-ID])

The SME of the FTO initiates the FT Request frame to the target AP by issuing an MLME-REMOTE-REQUEST.request primitive with parameters including the contents of the FT Request frame (FT Action frame with an FT Action field value indicating FT Request) to be sent. The MAC of the FTO transmits this Action frame. For processing at the current AP and target AP, see 13.10. When the MAC of the FTO receives the FT Response frame (FT Action frame with an FT Action field value indicating FT Response), it passes it to the SME by use of MLME-REMOTE-REQUEST.indication primitive, with parameters including the contents of the received Action frame. The MLME interfaces on the FTO, current AP, and the target AP for executing the over-the-DS fast BSS transition are shown in Figure 13-6.

The STA Address field of the FT Request frame shall be set to the MAC address of the FTO, and the Target AP Address field of the FT Request frame shall be set to the BSSID of the target AP. The elements in the FT Request frame, and their required contents, shall be as given in 13.8.2.

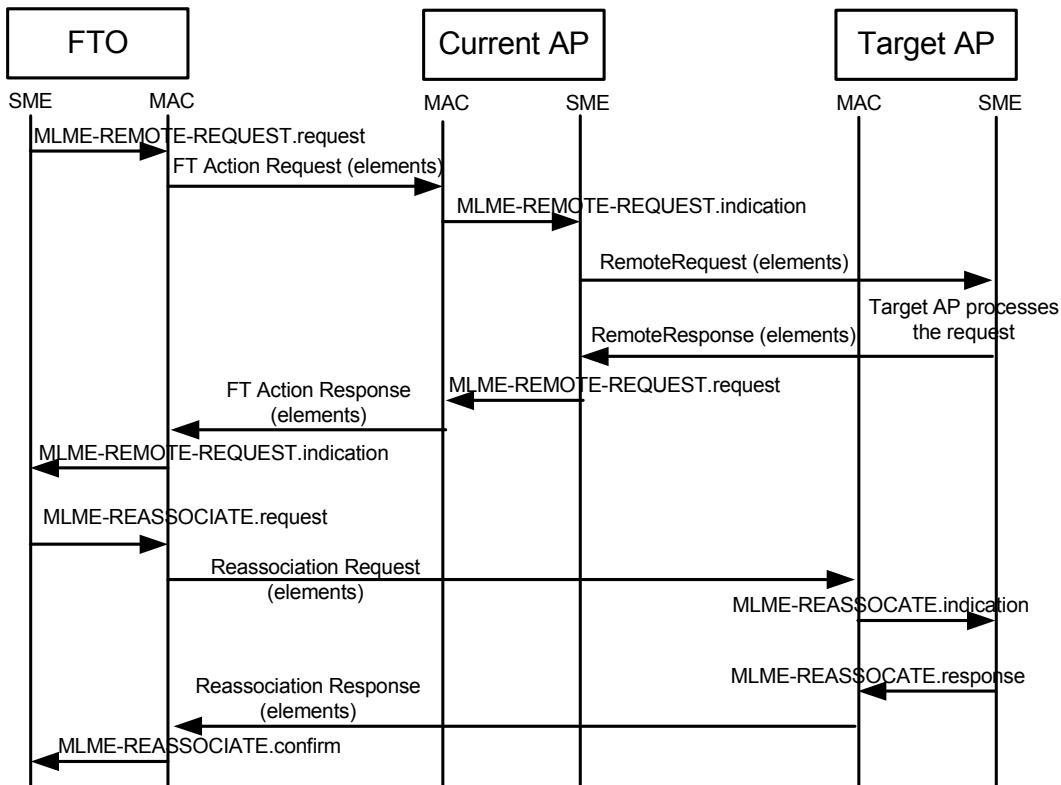

Figure 13-6—MLME interfaces for over-the-DS FT protocol messages

If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the FT Request frame with status code STATUS_INVALID_MDE. If the contents of the RSNE do not indicate a negotiated AKM of fast BSS transition (suite type 00-0F-AC:3, 00-0F-AC:4, or 00-0F-AC:9), the AP shall reject the FT Request frame with status code STATUS_INVALID_AKMP. If the FTE in the FT Request frame contains an invalid R0KH-ID, the AP shall reject the FT Request frame with status code STATUS_INVALID_FTE. If the RSNE in the FT Request frame contains an invalid PMKR0Name, and the AP has determined that it is an invalid PMKR0Name, the AP shall reject the authentication request with status code STATUS_INVALID_PMKID. If the requested R0KH is not reachable, the AP shall respond to the FT Request frame with status code R0KH_UNREACHABLE. The AP may reject the FT Request frame for limiting the FTO's reassociation to this AP by using the status code REQUEST_DECLINED. If the FTO selects a pairwise cipher suite in the RSNE that is different from the ones used in the initial mobility domain association, then the AP shall reject the FT Request frame with status code STATUS_INVALID_PAIRWISE_CIPHER.

The STA Address field of the FT Response frame shall be set to the MAC address of the FTO, and the Target AP Address field of the FT Response frame shall be set to the BSSID of the target AP. The elements in the FT Response frame, and their required contents, shall be as given in 13.8.3. The Status Code field shall be a value from the options listed in 9.4.1.9.

The R1KH of the target AP uses the value of PMKR0Name and other information from the frame to calculate PMKR1Name. If the target AP does not have the key identified by PMKR1Name, it may retrieve that key from the R0KH identified by the STA. See 13.2. Upon receiving a new PMK-R1 for a STA, the target AP shall delete the prior PMK-R1 security association and PTKSAs derived from the prior PMK-R1.

The FTO and the target AP compute the PTK and PTKName using the PMK-R1, PMKR1Name, ANonce, and SNonce, as specified in 12.7.1.7.5. The PTKSA shall be deleted by the target AP if it does not receive a Reassociation Request frame from the FTO within the reassociation deadline timeout value.

If the FTO does not receive a response to the FT Request frame, it may reissue the request following the restrictions given for Authentication frames in 11.3. If the Status Code field value returned by the target AP is SUCCESS, the FTO and target AP transition to State 2 (as defined in 11.3); the FTO may continue with reassociation (13.7.1). Handling of errors returned in the Status Code field shall be as specified for Authentication frames in 11.3.

13.5.4 Over-the-air FT protocol in a non-RSN

The over-the-air FT protocol in a non-RSN is shown in Figure 13-7.

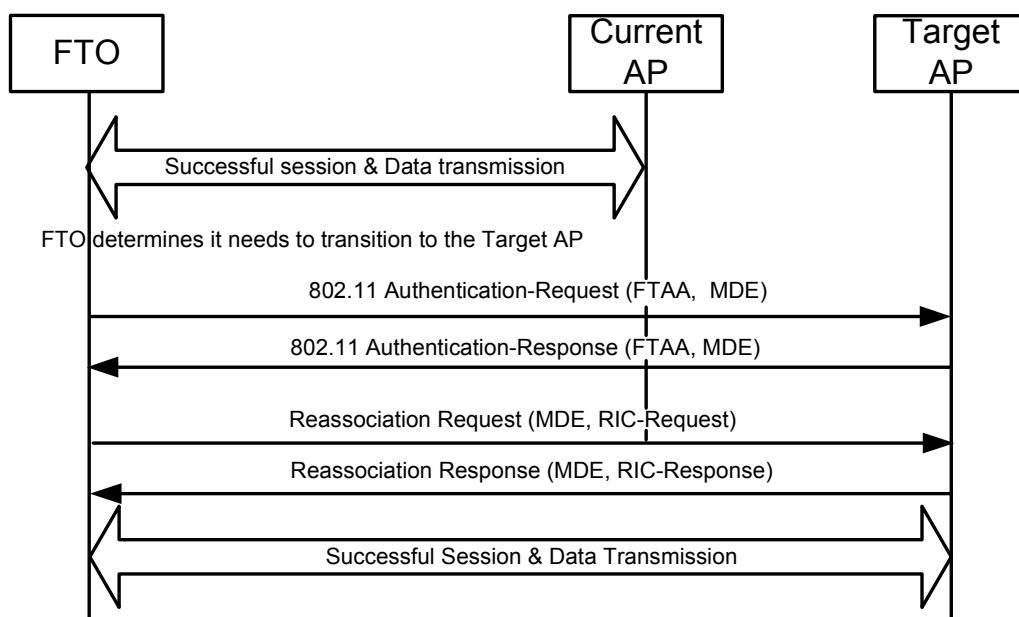

Figure 13-7—Over-the-air FT protocol in a non-RSN

To perform an over-the-air fast BSS transition to a target AP in a non-RSN, the FTO and target AP shall perform the following exchange:

- FTO→Target AP: Authentication-Request (FTAA, 0, MDE)
- Target AP→FTO: Authentication-Response (FTAA, Status, MDE)

In the Authentication-Request frame, the SA field of the message header shall be set to the MAC address of the FTO, and the DA field of the message header shall be set to the BSSID of the target AP. The elements in the frame, and their required contents, shall be as given in 13.8.2.

If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the authentication request with status code STATUS_INVALID_MDE.

In the Authentication-Response frame, the SA field of the message header shall be set to the BSSID of the target AP, and the DA field of the message header shall be set to the MAC address of the FTO. The Status Code field shall be a value from the options listed in 9.4.1.9. The elements in the frame, and their required contents, shall be as given in 13.8.3.

If the FTO does not receive a response to the Authentication-Request frame, it may reissue the request following the restrictions given for Authentication frames in 11.3. If the Status Code field value returned by the target AP is SUCCESS, the FTO and target AP transition to State 2 (as defined in 11.3); the FTO may continue with reassociation (13.7.2). Handling of errors returned in the Status Code field shall be as specified in 11.3.

13.5.5 Over-the-DS FT protocol in a non-RSN

The over-the-DS FT protocol in a non-RSN is shown in Figure 13-8.

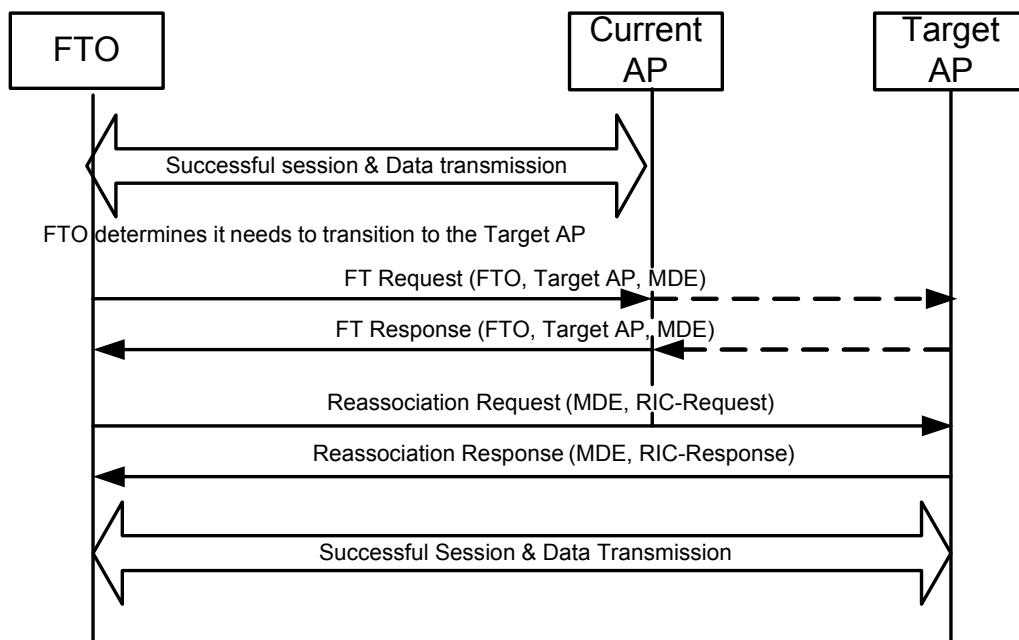

Figure 13-8—Over-the-DS FT protocol in a non-RSN

To perform an over-the-DS fast BSS transition to a target AP in a non-RSN, the FTO and the target AP (through the current AP) shall perform the following exchange:

FTO→Target AP: FT Request(FTO, TargetAP, MDE)

Target AP→FTO: FT Response(FTO, TargetAP, Status, MDE)

The STA Address field of the FT Request frame shall be set to the MAC address of the FTO, and the Target AP Address field of the FT Request frame shall be set to the BSSID of the target AP. The elements in the FT Request frame, and their required contents, shall be as given in 13.8.2.

If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the FT Request frame with status code STATUS_INVALID_MDE.

The STA Address field of the FT Response frame shall be set to the MAC address of the FTO, and the Target AP Address field of the FT Response frame shall be set to the BSSID of the target AP. The elements in the FT Response frame, and their required contents, shall be as given in 13.8.3. The Status Code field shall be a value from the options listed in 9.4.1.9.

If the FTO does not receive a response to the FT Request frame, it may reissue the request following the restrictions given for Authentication frames in 11.3. If the Status Code field value returned by the target AP

is SUCCESS, the FTO and target AP transition to State 2 (as defined in 11.3); the FTO may continue with reassociation (13.7.2). Handling of errors returned in the Status Code field shall be as specified for Authentication frames in 11.3.

13.6 FT resource request protocol

13.6.1 Overview

The FT resource request protocol involves an additional message exchange after the Authentication-Request/Response frame, or FT Request/Response frame, and prior to reassociation.

APs capable of fast BSS transition may allow FTOs to request resources prior to reassociation. Availability of the FT resource request protocol is advertised by the target AP in the MDE. If the Resource Request Protocol Capability subfield is 0, then the FTO shall not send an Authentication-Confirm nor FT Confirm frame to the AP. An AP that receives an Authentication-Confirm or FT Confirm frame from a STA and does not support the FT resource request protocol shall respond with status code INVALID_PARAMETERS.

The additional message exchange for the FT resource request protocol shall be performed using the same method (over-the-air or over-the-DS) as was used for the Authentication-Request/Response frame or FT Request/Response frame. An AP that receives an FT Confirm frame that did not previously receive an FT Request frame from the same STA shall reject the request with status code STATUS_INVALID_FT_ACTION_FRAME_COUNT. An AP that receives an Authentication-Confirm frame that did not previously receive an Authentication-Request frame from the same STA shall reject the request with status code TRANSACTION_SEQUENCE_ERROR.

13.6.2 Over-the-air fast BSS transition with resource request

The over-the-air FT resource request protocol in an RSN is shown in Figure 13-9.

The over-the-air FT resource request protocol in a non-RSN is shown in Figure 13-10.

To perform an over-the-air FT resource request protocol to a target AP, after completing the Authentication-Request/Response frame exchange given in 13.5.2 or 13.5.4, the FTO and target AP shall perform the following exchange:

FTO→Target AP: Authentication-Confirm (FTAA, 0, RSNE[PMKR1Name], MDE, FTE[MIC, ANonce, SNonce, R1KH-ID, R0KH-ID], RIC-Request)

Target AP→FTO: Authentication-Ack (FTAA, Status, RSNE[PMKR1Name], MDE, FTE[MIC, ANonce, SNonce, R1KH-ID, R0KH-ID], RIC-Response)

The SME of the FTO initiates the resource request exchange through the use of the primitive MLME-RESOURCE-REQUEST.request primitive, and the SME of the AP responds with MLME-RESOURCE-REQUEST.response primitive.

In the Authentication-Confirm frame, the SA field of the message header shall be set to the MAC address of the FTO, and the DA field of the message header shall be set to the BSSID of the target AP. In a non-RSN, the FTE and RSNE shall not be present. The elements in the frame, the element contents, and MIC calculation shall be as given in 13.8.4.

If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the Authentication-Confirm frame with status code STATUS_INVALID_MDE.

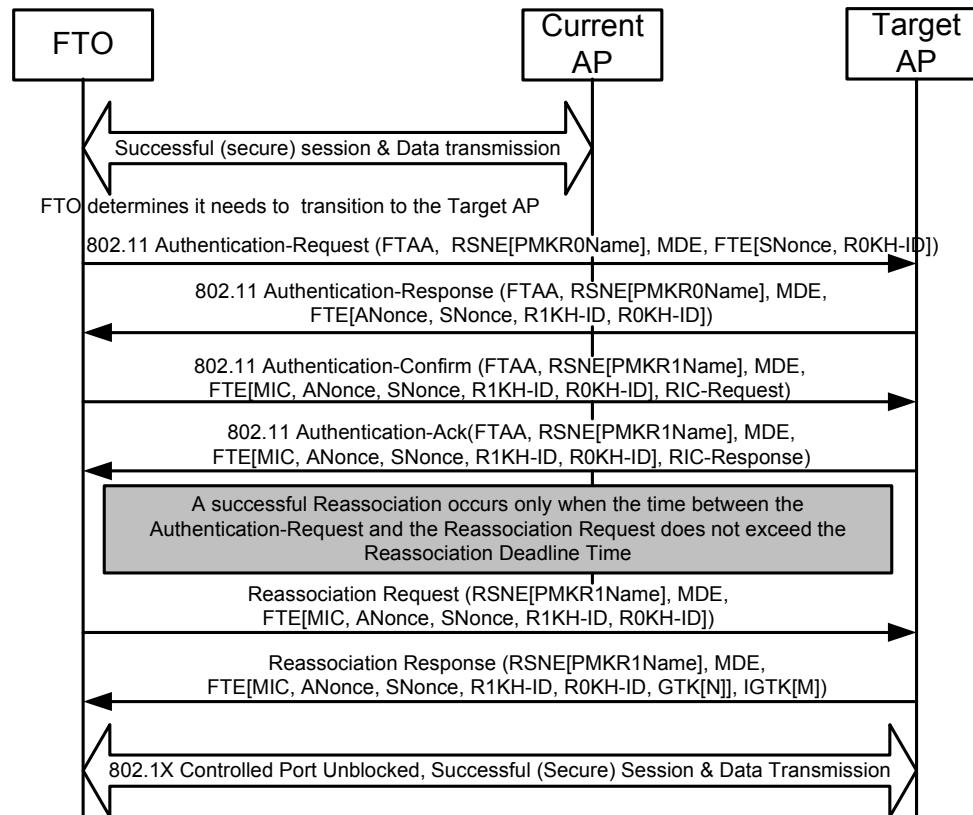

Figure 13-9—Over-the-air FT resource request protocol in an RSN

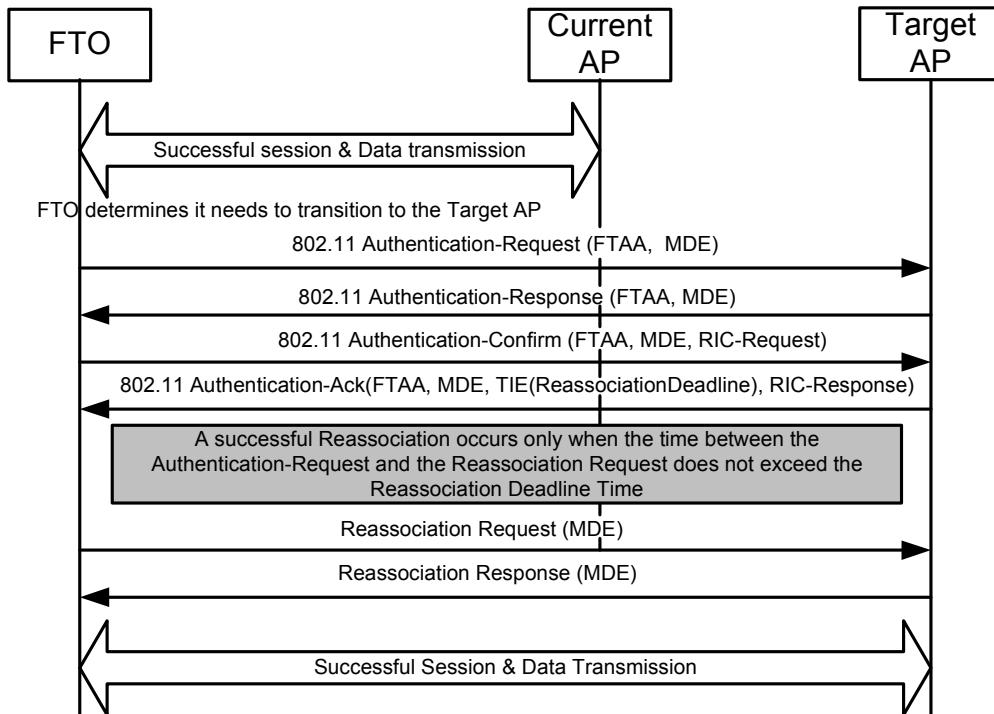

Figure 13-10—Over-the-air FT resource request protocol in a non-RSN

In an RSN, the R1KH of the target AP verifies the MIC in the FTE in the Authentication-Confirm frame and shall discard the request if it is incorrect. If the FTE in the Authentication-Confirm frame contains a different R0KH-ID, R1KH-ID, ANonce, or SNonce, the AP shall reject the Authentication-Confirm frame with status code STATUS_INVALID_FTE. If the RSNE in the Authentication-Confirm frame contains an invalid PMKR1Name, the AP shall reject the Authentication-Confirm frame with status code STATUS_INVALID_PMKID.

In the Authentication-Ack frame, the SA field of the message header shall be set to the BSSID of the target AP, and the DA field of the message header shall be set to the MAC address of the FTO. In a non-RSN, the FTE and RSNE shall not be present. The Status Code field shall be a value from the options listed in 9.4.1.9. The elements in the frame, the element contents, and MIC calculation shall be as given in 13.8.5.

In an RSN, the S1KH of the FTO verifies the MIC in the FTE in the Authentication-Ack frame and shall discard the response if the MIC is incorrect.

The FTO may make a request for resources by including a RIC-Request (see 13.11) in the Authentication-Confirm frame. The RIC-Request is generated by the procedures of 13.11.3.1, and the RIC-Response is generated by the procedures of 13.11.3.2.

If the value of the Status Code field returned by the target AP in the Authentication-Ack frame is not SUCCESS, then the FTO shall abandon this transition attempt.

In an RSN, on successful completion of the FT authentication exchange of the FT resource request protocol, the PTKSA has been established and proven live. The key replay counter shall be initialized to 0, and the subsequent EAPOL-Key frames (e.g., GTK and IGTK updates) shall use the key replay counter to detect and discard replays. The PTKSA shall be deleted by the target AP if it does not receive a Reassociation Request frame from the FTO within the reassociation deadline timeout value.

In a non-RSN, the Authentication-Ack frame contains a TIE with a reassociation deadline. If the FTO does not send a Reassociation Request frame to the target AP within that interval, the FTO shall abandon this transition attempt.

The exchange between the FTO and the target AP may continue with reassociation (13.7.1 or 13.7.2).

13.6.3 Over-the-DS fast BSS transition with resource request

The over-the-DS FT resource request protocol in an RSN is shown in Figure 13-11.

The over-the-DS FT resource request protocol in a non-RSN is shown in Figure 13-12.

To perform an Over-the-DS FT resource request protocol to a target AP, after completing the FT Request/Response frame exchange given in 13.5.3 or 13.5.5, the FTO and target AP (through the current AP) shall perform the following exchange, using the mechanism described in 13.10:

FTO→Target AP: FT Confirm (FTO, TargetAP, RSNE[PMKR1Name], MDE, FTE[MIC, ANonce, SNonce, R1KH-ID, R0KH-ID], RIC-Request)

Target AP→FTO: FT Ack (FTO, TargetAP, Status, RSNE[PMKR1Name], MDE, FTE[MIC, ANonce, SNonce, R1KH-ID, R0KH-ID], TIE[ReassociationDeadline], RIC-Response)

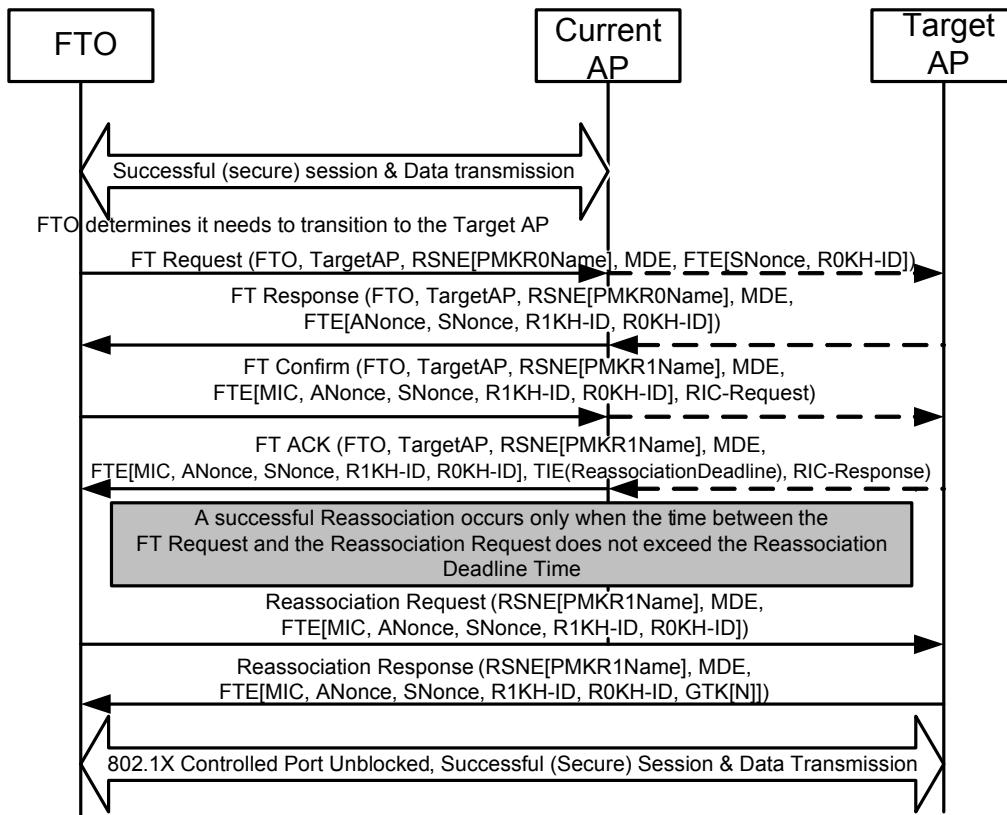

Figure 13-11—Over-the-DS FT resource request protocol in an RSN

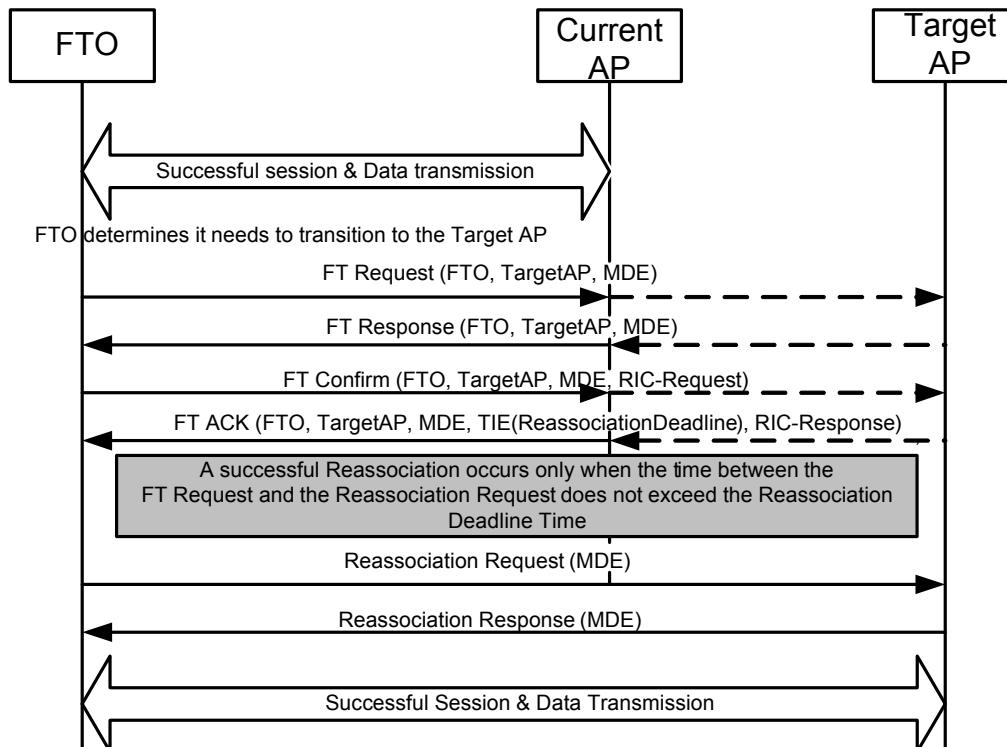

Figure 13-12—Over-the-DS FT resource request protocol in a non-RSN

The SME of the FTO initiates the FT Confirm frame to the target AP by issuing an MLME-REMOTE-REQUEST.request primitive with parameters including the contents of the FT Confirm frame (FT Action frame with an FT Action field value indicating FT Confirm) to be sent. The MAC of the FTO transmits this Action frame. For processing at the current AP and target AP, see 13.10. When the MAC of the FTO receives the FT Ack frame (FT Action frame with an FT Action field value indicating FT Ack), it passes it to the SME by use of an MLME-REMOTE-REQUEST.indication primitive, with parameters including the contents of the received Action frame.

The STA Address field of the FT Confirm frame shall be set to the MAC address of the FTO, and the Target AP Address field of the FT Confirm frame shall be set to the BSSID of the target AP. The elements in the FT Confirm frame, the element contents, and the MIC calculation shall be as given in 13.8.4. In a non-RSN, the FTE and RSNE shall not be present.

If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the FT Confirm frame with status code STATUS_INVALID_MDE.

In an RSN, the R1KH of the target AP verifies the MIC in the FTE and shall discard the request if it is incorrect. If the FTE in the FT Confirm frame contains a different R0KH-ID, R1KH-ID, ANonce, or SNonce from the values sent in the FT Response frame, the AP shall reject the FT Confirm frame with status code STATUS_INVALID_FTE. If the RSNE in the FT Confirm frame contains an invalid PMKR1Name, the AP shall reject the FT Confirm frame with status code STATUS_INVALID_PMKID.

The STA Address field of the FT Ack frame shall be set to the MAC address of the FTO, and the Target AP Address field of the FT Ack frame shall be set to the BSSID of the target AP. The elements in the FT Ack frame, the element contents, and the MIC calculation shall be as given in 13.8.5. In a non-RSN, the FTE and RSNE shall not be present. The Status Code field value shall be a value from the options listed in 9.4.1.9, and a TIE may appear.

In an RSN, the S1KH of the FTO verifies the MIC in the FTE in the FT Ack frame and shall discard the response if the MIC is incorrect.

The FTO may make a request for resources by including a RIC-Request (see 13.11) in the FT Confirm frame. The RIC-Request is generated by the procedures of 13.11.3.1, and the RIC-Response is generated by the procedures of 13.11.3.2.

In order to recover from over-the-DS packet losses, the FTO may retransmit the FT Confirm frame until the reassociation deadline time is reached. If the FTO does not receive a response to the FT Confirm frame or if the value of the Status Code field returned by the target AP in the FT Ack frame is not SUCCESS, then the FTO shall abandon this transition attempt.

In an RSN, on successful completion of the FT Confirm/Acknowledgment frame exchange, the PTKSA has been established and proven live. The key replay counter shall be initialized to 0, and the subsequent EAPOL-Key frames (e.g., GTK and IGTK updates) shall use the key replay counter to detect and discard replays. The PTKSA shall be deleted by the target AP if it does not receive a Reassociation Request frame from the FTO within the reassociation deadline timeout value. Resource request procedures are specified in 13.11.

In a non-RSN, the FT Ack frame contains a TIE with a reassociation deadline. If the FTO does not send a Reassociation Request frame to the target AP within that interval, the FTO shall abandon this transition attempt.

The exchange between the FTO and the target AP may continue with reassociation (13.7.1 or 13.7.2).

13.7 FT reassociation

13.7.1 FT reassociation in an RSN

If the FTO does not send a Reassociation Request frame to the target AP within the reassociation deadline interval received during the FT initial mobility domain association, the target AP may delete the PTKSA, and the FTO shall abandon this transition attempt.

The FTO shall perform a reassociation directly with the target AP via the following exchange:

FTO→Target AP: Reassociation Request(RSNE[PMKR1Name], MDE, FTE[MIC, ANonce, SNonce, R1KH-ID, R0KH-ID], RIC-Request)

Target AP→FTO: Reassociation Response(RSNE[PMKR1Name], MDE, FTE[MIC, ANonce, SNonce, R1KH-ID, R0KH-ID, GTK[N], IGTK[M]], RIC-Response)

The SME of the FTO initiates the reassociation through the use of the MLME-REASSOCIATE.request primitive. The SME of the AP responds to the indication with MLME-REASSOCIATE.response primitive. See 11.3.5.

In the Reassociation Request frame, the SA field of the message header shall be set to the MAC address of the FTO, and the DA field of the message header shall be set to the BSSID of the target AP. The elements in the frame, the element contents, and the MIC calculation shall be as given in 13.8.4.

The R1KH of the target AP verifies the MIC in the FTE in the Reassociation Request frame and shall discard the request if the MIC is incorrect. If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the Reassociation Request frame with status code STATUS_INVALID_MDE. If the FTE in the Reassociation Request frame contains a different R0KH-ID, R1KH-ID, ANonce, or SNonce, the AP shall reject the Reassociation Request frame with status code STATUS_INVALID_FTE. If the RSNE in the Reassociation Request frame contains an invalid PMKR1Name, the AP shall reject the Reassociation Request frame with status code STATUS_INVALID_PMKID.

In the Reassociation Response frame, the SA field of the message header shall be set to the BSSID of the target AP, and the DA field of the message header shall be set to the MAC address of the FTO. The Status Code field shall be a value from the options listed in 9.4.1.9. The elements in the frame, the element contents, and the MIC calculation shall be as given in 13.8.5.

The S1KH of the FTO verifies the MIC in the FTE in the Reassociation Response frame and shall discard the response if the MIC is incorrect.

If an FTO is performing a reassociation exchange as part of the FT resource request protocol, then the FTO shall not include the RIC-Request in the Reassociation Request frame, and the AP shall not include the RIC-Response in the Reassociation Response frame. If the reassociation exchange is part of the FT resource request protocol and the AP is unable to honor the resources that have been placed in the accepted state for that FTO, then the AP shall reject the Reassociation Request frame and may use status code DENIED_INSUFFICIENT_BANDWIDTH.

If the FTO did not utilize the FT resource request protocol, the FTO may make a request for resources by including a RIC-Request (see 13.11) in the Reassociation Request frame. The RIC-Request is generated by the procedures of 13.11.3.1, and the RIC-Response is generated by the procedures of 13.11.3.2.

If the Status Code field value returned by the target AP in the response is REFUSED_REASON_UNSPECIFIED, TRANSACTION_SEQUENCE_ERROR, or REJECTED_SEQUENCE_TIMEOUT, then the FTO shall abandon this transition attempt. Handling of other errors returned in the Status Code field shall be as specified in 11.3.

Upon a successful reassociation, the PTKSA has been established and proven live. The SME of the AP shall open the IEEE 802.1X Controlled Port. The FTO shall transition to State 4 (as defined in 11.3). If the target AP is distinct from the previous AP, the FTO shall enter State 1 with respect to the previous AP.

Upon a successful reassociation, the FTO shall delete any corresponding PTKSA with its previous AP. The SME of the FTO shall issue an MLME-DELETEKEYS.request primitive to delete the pairwise keys with the previous AP, and the FTO and the AP shall issue an MLME-SETKEYS.request primitive and MLME-SETPROTECTION.request primitive to install the pairwise keys. The PTK lifetime timer shall be initialized with the value calculated as the difference between the TIE[KeyLifetime] sent in message 3 of the FT initial mobility domain association and the time since the completion of the FT 4-way handshake during the FT initial mobility domain association.

When the IEEE 802.1X Controlled Port is opened, the EAPOL-Key frame replay counter shall be initialized to 0. The R1KH shall increment the key replay counter on each successive EAPOL-Key frame that it transmits.

13.7.2 FT reassociation in a non-RSN

The FTO shall perform a reassociation with the target AP via the following exchange:

FTO→Target AP: Reassociation Request(MDE, RIC-Request)
Target AP→FTO: Reassociation Response(MDE, RIC-Response)

The SME of the FTO initiates the reassociation through the use of the MLME-REASSOCIATE.request primitive. The SME of the AP responds to the indication with MLME-REASSOCIATE.response primitive. See 11.3.5.

In the Reassociation Request frame, the SA field of the message header shall be set to the MAC address of the FTO, and the DA field of the message header shall be set to the BSSID of the target AP. The elements in Reassociation Request frame, and their required contents, shall be as given in 13.8.4.

If the contents of the MDE received by the target AP do not match the contents advertised in the Beacon and Probe Response frames, the target AP shall reject the Reassociation Request frame with status code STATUS_INVALID_MDE.

In the Reassociation Response frame, the SA field of the message header shall be set to the BSSID of the target AP, and the DA field of the message header shall be set to the MAC address of the FTO. The elements in Reassociation Response frame, and their required contents, shall be as given in 13.8.5. The Status Code field shall be a value from the options listed in 9.4.1.9.

If the FTO is performing a reassociation exchange as part of the FT resource request protocol, then the FTO shall not include the RIC-Request in the Reassociation Request frame, and the AP shall not include the RIC-Response in the Reassociation Response frame.

If the FTO did not utilize the FT resource request protocol, the FTO may make a request for resources by including a RIC-Request (see 13.11) in the Reassociation Request frame. The RIC-Request is generated by the procedures of 13.11.3.1, and the RIC-Response is generated by the procedures of 13.11.3.2.

If the Status Code field value returned by the target AP in the response is REFUSED_REASON_UNSPECIFIED, TRANSACTION_SEQUENCE_ERROR, or REJECTED_SEQUENCE_TIMEOUT, then the FTO shall abandon this transition attempt. Handling of other errors returned in the Status Code field shall be as specified in 11.3.

If the AP has dot11RSNAActivated equal to true, upon a successful reassociation, the SME shall open the IEEE 802.1X Controlled Port.

Upon a successful reassociation, the target AP and the FTO shall transition to State 4 (as defined in 11.3). If the target AP is distinct from the previous AP, then the FTO shall enter State 1 with respect to the previous AP.

13.8 FT authentication sequence

13.8.1 Overview

The FT authentication sequence comprises four sets of FT elements. Each set of FT elements is referred to in 13.8 as a *message*. These messages are included in the FT Protocol frames or FT Resource Request Protocol frames to initiate a fast BSS transition. The FT authentication sequence is always initiated by the FTO and responded to by the target AP.

In an RSN, the first two messages in the sequence allow the FTO and target AP to provide association instance identifiers, SNonce and ANonce, respectively. SNonce and ANonce are chosen randomly or pseudorandomly and are used to generate a fresh PTK. The first two messages also enable the target AP to provision the PMK-R1 and the FTO and target AP to compute the PTK. The third and fourth messages demonstrate liveness of the peer, authenticate the elements, and enable an authenticated resource request.

When an FTO invokes the FT protocol, then the first two messages of the sequence are both carried in Authentication frames or both carried in Action frames, and these messages are described in 13.8.2 and 13.8.3. The third and fourth messages in the sequence are carried in the Reassociation Request and Reassociation Response frames and are described in 13.8.4 and 13.8.5.

When the FTO invokes the FT resource request protocol, then the first four messages of the sequence are all carried in Authentication frames or all carried in Action frames, and these messages are described in 13.8.2 to 13.8.5. The fifth and sixth frames of the FT resource request protocol are carried in the Reassociation Request frame and Reassociation Response frame and are described in 13.8.4 and 13.8.5.

Regardless of the transport mechanism, the information contained in the FT authentication sequence consists of the set of elements shown in Table 13-1.

The first message is used by the FTO to initiate a fast BSS transition. When RSNA is enabled, the FTO shall include the R0KH-ID and the SNonce in the FTE and the PMKR0Name in the RSNE. The target AP can use the PMKR0Name to derive the PMK1Name, and if the target AP does not have the PMK-R1 identified by PMK1Name, it may attempt to retrieve that key from the R0KH identified by R0KH-ID. See 13.2. The FTO includes a fresh SNonce as its contribution to the association instance identifier and to provide key separation of the derived PTK; it is selected randomly to serve as a challenge that demonstrates the liveness of the peer in the fourth message.

The second message is used by the target AP to respond to the requesting FTO. The target AP provides the key holder identifiers and key names used to generate the PTK. The target AP also includes a fresh ANonce as its contribution to the association instance identifier and to provide key separation of the derived PTK. The response includes a status code.

Table 13-1—FT authentication elements

| Information | Presence in Authentication Sequence messages | Description |
|---|---|-------------|
| RSN | The RSNE is present if dot11RSNAActivated is true. | 9.4.2.25 |
| Mobility Domain | The Mobility Domain element is present. | 9.4.2.47 |
| Fast BSS Transition | The Fast BSS Transition element is present if dot11RSNAActivated is true. | 9.4.2.48 |
| Timeout Interval (reassociation deadline) | The Timeout Interval element is optionally present in the fourth message of the sequence if dot11RSNAActivated is not true. | 9.4.2.49 |
| RIC | The RIC Data element is optionally present in the third and fourth messages. | 9.4.2.50 |

In an RSN, the third message is used by the FTO to assert to the target AP that it has a valid PTK. If no resources are required, then the FTO omits inclusion of the RIC.

The fourth message is used by the target AP to respond to the requesting FTO. This message serves as final confirmation of the transition, establishes that the AP possesses the PMK-R1 and is participating in this association instance, and protects against downgrade attacks. Note, however, that the RIC is absent if no resources were requested in the third message. This also includes a status code and may include a reassociation deadline.

13.8.2 FT authentication sequence: contents of first message

The RSNE shall be present only if dot11RSNAActivated is true. If present, the RSNE shall be set as follows:

- Version field shall be set to 1.
- PMKID Count field shall be set to 1.
- PMKID List field shall contain the PMKROName.
- All other fields shall be as specified in 9.4.2.25 and 12.6.3.

The MDE shall contain the MDID field and the FT Capability and Policy field settings obtained from the target AP, as advertised by the target AP in Beacon and Probe Response frames. The MDID shall be identical to that obtained during the FT initial mobility domain association exchange.

The FTE shall be present only if dot11RSNAActivated is true. If present, the FTE shall be set as follows:

- R0KH-ID shall be the value of R0KH-ID obtained by the FTO during its FT initial mobility domain association exchange.
- SNonce shall be set to a value chosen randomly by the FTO, following the recommendations of 12.7.5.
- All other fields shall be set to 0.

13.8.3 FT authentication sequence: contents of second message

If the status code is SUCCESS, then the following rules apply.

The RSNE shall be present only if dot11RSNAActivated is true. If present, the RSNE shall be set as follows:

- Version field shall be set to 1.
- PMKID Count field shall be set to 1.

- PMKID List field shall be set to the value contained in the first message of this sequence.
- All other fields shall be identical to the contents of the RSNE advertised by the AP in Beacon and Probe Response frames.

The MDE shall contain the MDID and FT Capability and Policy fields. This element shall be the same as the MDE advertised by the target AP in Beacon and Probe Response frames.

The FTE shall be present only if dot11RSNAActivated is true. If present, the FTE shall be set as follows:

- R0KH-ID shall be identical to the R0KH-ID provided by the FTO in the first message.
- R1KH-ID shall be set to the R1KH-ID of the target AP, from dot11FTR1KeyHolderID.
- ANonce shall be set to a value chosen randomly by the target AP, following the recommendations of 12.7.5.
- SNonce shall be set to the value contained in the first message of this sequence.
- All other fields shall be set to 0.

13.8.4 FT authentication sequence: contents of third message

The RSNE shall be present only if dot11RSNAActivated is true. If present, the RSNE shall be set as follows:

- Version field shall be set to 1.
- PMKID Count field shall be set to 1.
- PMKID field shall contain the PMKR1Name.
- All other fields shall be as specified in 9.4.2.25 and 12.6.3.

The MDE shall contain the MDID and FT Capability and Policy fields. This element shall be identical to the MDE contained in the first message of this sequence.

The FTE shall be present only if dot11RSNAActivated is true. If present, the FTE shall be set as follows:

- ANonce, SNonce, R0KH-ID, and R1KH-ID shall be set to the values contained in the second message of this sequence.
- The Element Count field of the MIC Control field shall be set to the number of elements protected in this frame (variable).
- When the negotiated AKM is 00-0F-AC:3, 00-0F-AC:4, or 00-0F-AC:9, the MIC shall be calculated using the KCK and the AES-128-CMAC algorithm. The output of the AES-128-CMAC shall be 128 bits.
- The MIC shall be calculated on the concatenation of the following data, in the order given here:
 - FTO's MAC address (6 octets)
 - Target AP's MAC address (6 octets)
 - Transaction sequence number (1 octet), which shall be set to the value 5 if this is a Reassociation Request frame and, otherwise, set to the value 3
 - RSNE
 - MDE
 - FTE, with the MIC field of the FTE set to 0
 - Contents of the RIC-Request (if present)
- All other fields shall be set to 0.

If resources are being requested by the FTO, then a sequence of elements forming the RIC-Request shall be included.

13.8.5 FT authentication sequence: contents of fourth message

If the status code is SUCCESS, then the following rules apply.

The RSNE shall be present only if dot11RSNAActivated is true. If present, the RSNE shall be set as follows:

- Version field shall be set to 1.
- PMKID Count field shall be set to 1.
- PMKID field shall contain the PMKR1Name
- All other fields shall be identical to the contents of the RSNE advertised by the target AP in Beacon and Probe Response frames.

The MDE shall contain the MDID and FT Capability and Policy fields. This element shall be identical to the MDE contained in the second message of this sequence.

The FTE shall be present only if dot11RSNAActivated is true. If present, the FTE shall be set as follows:

- ANonce, SNonce, R0KH-ID, and R1KH-ID shall be set to the values contained in the second message of this sequence.
- The Element Count field of the MIC Control field shall be set to the number of elements protected in this frame (variable).
- When this message of the authentication sequence appears in a Reassociation Response frame, the Optional Parameter(s) field in the FTE may include the GTK and IGTK subelements. If a GTK or an IGTK are included, the Key field of the subelement shall be encrypted using KEK and the NIST AES key wrap algorithm. The Key field shall be padded before encrypting if the key length is less than 16 octets or if it is not a multiple of 8. The padding consists of appending a single octet 0xdd followed by zero or more 0x00 octets. When processing a received message, the receiver shall ignore this trailing padding. Addition of padding does not change the value of the Key Length field. Note that the length of the encrypted Key field can be determined from the length of the GTK or IGTK subelement.
- When the negotiated AKM is 00-0F-AC:3, 00-0F-AC:4, or 00-0F-AC:9, the MIC shall be calculated using the KCK and the AES-128-CMAC algorithm. The output of the AES-128-CMAC algorithm shall be 128 bits.
- The MIC shall be calculated on the concatenation of the following data, in the order given here:
 - FTO's MAC address (6 octets)
 - Target AP's MAC address (6 octets)
 - Transaction sequence number (1 octet), which shall be set to the value 6 if this is a Reassociation Response frame or, otherwise, set to the value 4
 - RSNE
 - MDE
 - FTE, with the MIC field of the FTE set to 0
 - Contents of the RIC-Response (if present)
- All other fields shall be set to 0.

If this message is other than a Reassociation Response frame and dot11RSNAActivated is false, a TIE may appear. If this message is other than a Reassociation Response frame, includes a RIC-Response, and dot11RSNAActivated is false, then a timeout interval shall appear. If it appears, it shall be set as follows:

- Timeout Interval Type field shall be set to 1 (reassociation deadline)
- Timeout Interval Value field shall be set to the reassociation deadline time.

If resources were requested by the FTO, then a RIC-Response shall be included.

13.9 FT security architecture state machines

13.9.1 Introduction

The FT state machines describe the interaction between the RSNA key management and IEEE 802.11 architectural components.

RSNA key management uses the MA-UNITDATA service primitives to send/receive EAPOL-Key frames for FT initial association; MLME interfaces described below for FT methods; and MLME-SETKEYS, MLME-DELETEKEYS, and MLME-SETPROTECTION primitives. FT key management uses the following primitives for key management delivery and reception:

- The MLME-REMOTE-REQUEST primitives for FT key management over the DS
- The MLME-AUTHENTICATE primitives for FT key management over the air
- The MLME-RESOURCE-REQUEST primitives for FT resource request over the air
- The MLME-REASSOCIATE primitives for FT key management over the air and over the DS

Some of the state machine design considerations are as follows:

- Details of error handling are not included in the state machines. See 13.4, 13.5, and 13.6.
- Retransmission of FT Authentication and (Re)Association frames are not included in the state machines; see 13.5 and 13.6.

Various signals are used to communicate between the R0KH and the R1KH state machines. Note that these interactions may be between separate entities, rather than within a single SME. These interactions are as follows:

- In the R0KH state machine, FT-PMKR1-SA (PMKR1-SA) sends a PMK-R1 PMKSA to the R1KH.
- In the R1KH state machine, FT-FULL-AUTH (R1KH-ID) requests a key from the R0KH.
- In the R1KH state machine, FT-Transition-Auth (R1KH-ID) requests a key from the R0KH that was used for the initial mobility domain association.

The interactions between the R0KH and IEEE Std 802.1X, between the R1KH and IEEE Std 802.1X, and between the S1KH and IEEE Std 802.1X occur within the SME. At both the target AP and at the FTO, the R1KH and S1KH initialize the IEEE 802.1X EAPOL state machines in the respective SMEs. The Controlled Port is opened without an EAP exchange when the reassociation completes.

13.9.2 R0KH state machine

13.9.2.1 General

There is one R0KH state machine, which includes FT key management.

The state diagram in Figure 13-13 consists of a set of states that handle R0KH functions including key hierarchy instantiation, key generation, and cleanup. This state machine interacts with the R1KH state machine.

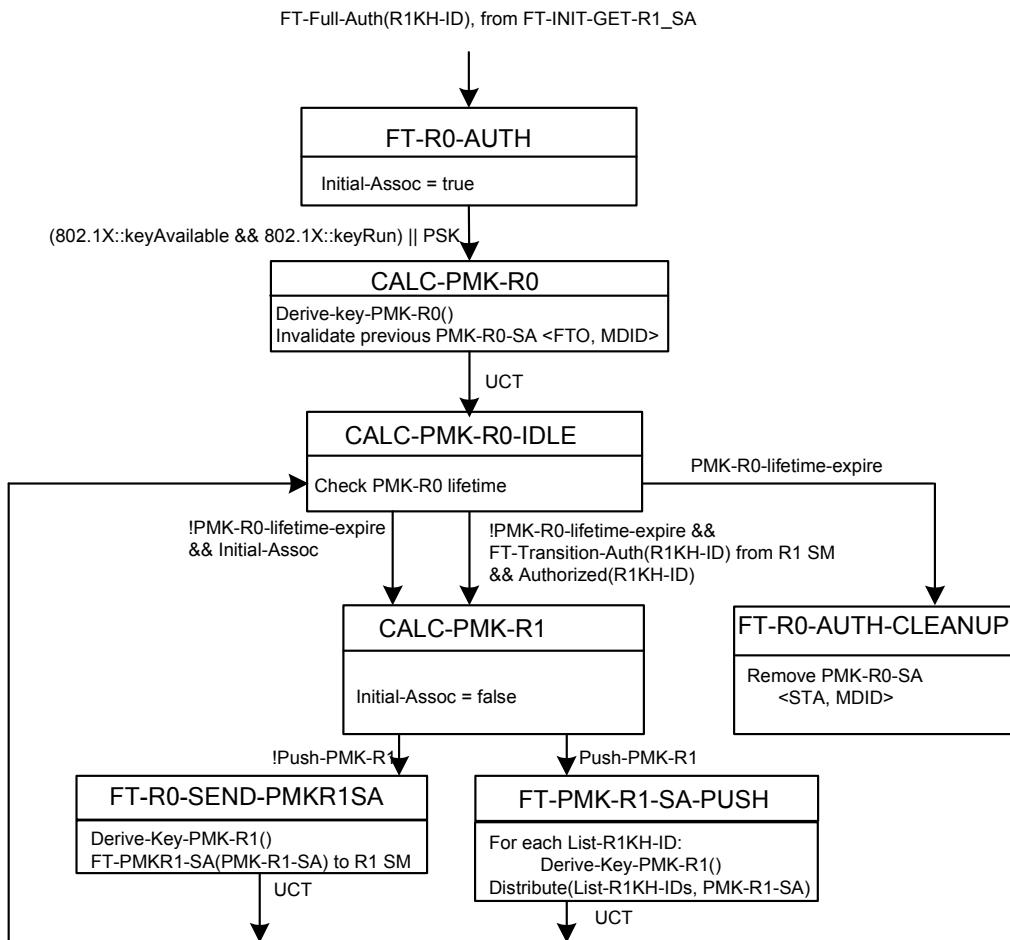

Figure 13-13—R0KH state machine

13.9.2.2 R0KH state machine states

The following list summarizes the states of the R0KH state machine:

- **CALC-PMK-R0**: This state is entered after the MSK from EAP authentication or PSK is available.
- **CALC-PMK-R0-IDLE**: This state is an intermediate state for the R0KH to wait for new requests from R1KHS.
- **CALC-PMK-R1**: For FT initial association, this state is entered as an unconditional transfer. For FT methods, this state is entered through the event from an R1KH state machine.
- **FT-PMK-R1-SA-PUSH**: This state is entered if Push-PMK-R1 is true. PMK-R1s are derived and distributed to all of the configured R1KHS.
- **FT-R0-AUTH-CLEANUP**: This state is entered when the PMK-R0 lifetime expires.
- **FT-R0-AUTH**: This state is entered through the event from the R1KH state machine. The R1KH state machine sends this event when it determines that a new PMK-R0 is needed.
- **FT-R0-SEND-PMKR1SA**: This state is entered from CALC-PMK-R1 when a request for the PMK-R1 security association is received from an R1KH. PMK-R1 security association is derived and distributed to the requesting R1KH.

13.9.2.3 R0KH state machine variables

The following list summarizes the variables used by the R0KH state machine:

- *Initial-Assoc* – This variable is used to indicate whether the current authentication is the initial association, in order to trigger the initial derivation of PMK-R1.
- *List-R1KH-IDs* – This variable contains a list of all of the R1KH-IDs in the mobility domain. This list is populated by the key distribution protocol as required in 13.2.
- *PMK-R0-lifetime-expire* – This variable is set to true when PMK-R0 lifetime is deemed expired.
- *PSK* – This variable is set to true when authentication is performed by use of a preshared key.
- *Push-PMK-R1* – This variable is set to true when R0KH can push the PMK-R1 security associations to R1KHS.

13.9.2.4 R0KH state machine procedures

The following list summarizes the procedures used by the R0KH state machine:

- **Authorized(R1KH-ID)** – This procedure returns a value of true if the R1KH is a known key holder in the mobility domain.
- **Distribute (List-R1KH-IDs, PMK-R1 PMKSA)** – Distributes the PMK-R1-SAs for the current instance of the key hierarchy to the list of R1KH-IDs.
- **Derive-Key-PMK-R0()** – This procedure derives the PMK-R0 from the MSK or PSK, derives the PMKROName (as described in 12.7.1.7.3), and creates PMK-R0 security association.
- **Derive-Key-PMK-R1 (R1KH-ID)** – From the PMK-R0, and the R1KH-ID (as described in 12.7.1.7.4) for the R1KH identified by R1KH-ID, this procedure derives the PMK-R1 and creates a PMK-R1 security association.

13.9.3 R1KH state machine

13.9.3.1 General

The R1KH state machine includes functions for FT initial association and FT protocols. The R1KH states performing FT initial association and the R1KH states performing FT protocol exchanges interact differently with the R0KH state machine.

The R1KH state machine and other portions of the SME are defined in Figure 13-14 and Figure 13-15 and consist of a set of states that handle FT initial mobility domain association, PMK-R1 reception, PTK handshake and session establishment, FT protocols (including resource requests), and cleanup. This state machine interacts with the R0KH state machine to generate a fresh FT key hierarchy for the initial mobility domain association and to get the PMK-R1 security association (PMK-R1 PMKSA) for the FT protocols. While the figures show the over-the-air message exchanges, the over-the-DS exchanges are handled similarly.

A new instance of the R1KH state machine is created each time initial mobility domain association or fast BSS transition is initiated.

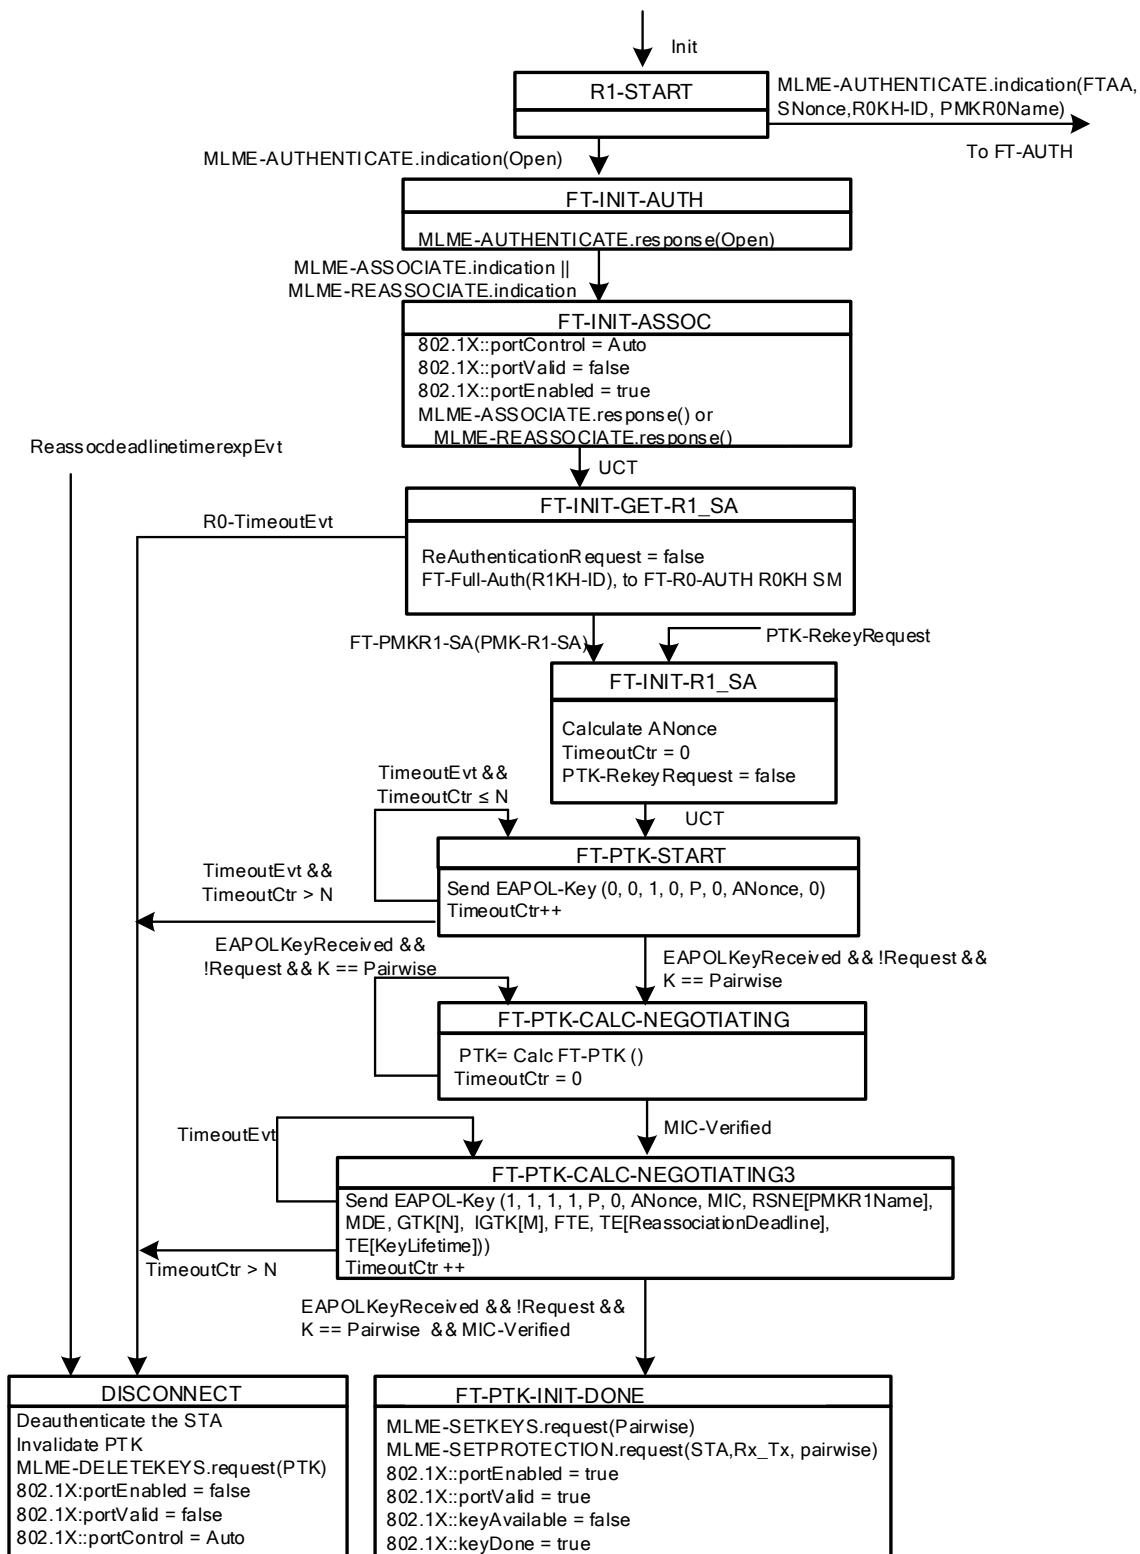

Figure 13-14—R1KH state machine, including portions of the SME (part 1)

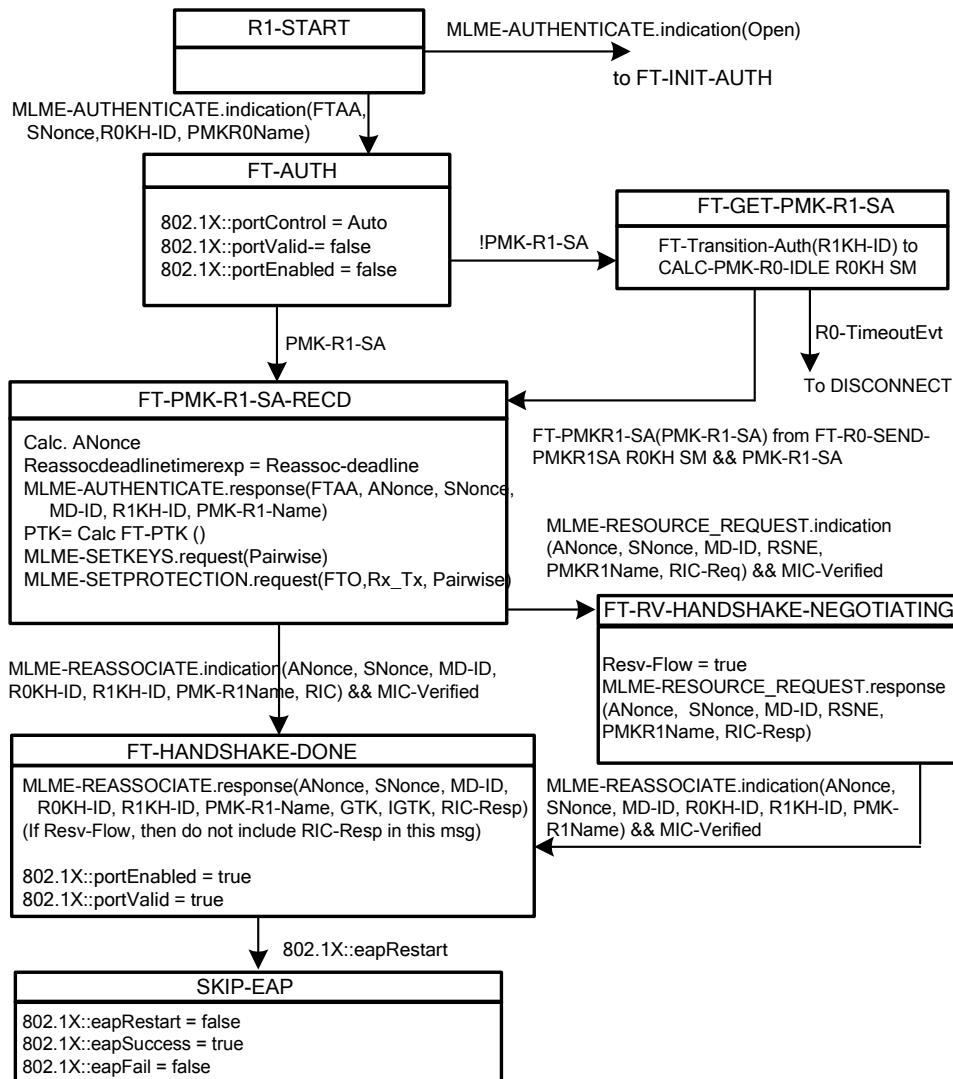

Figure 13-15—R1KH state machine, including portions of the SME (part 2)

13.9.3.2 R1KH state machine states

The following list summarizes the states of the R1KH state machine:

- **DISCONNECT**: This state is entered when the current session ends or when errors occur.
- **FT-AUTH**: This state is entered upon receipt of an indication that an FT protocol or FT resource request protocol is invoked.
- **FT-GET-PMK-R1-SA**: This state is entered when R1KH sends a message to the R0KH to get the PMK-R1-SA.
- **FT-HANDSHAKE-DONE**: This state is entered when reassociation indication parameters are validated. The Reassociation Response frame is then sent.
- **FT-INIT-ASSOC**: This state is entered upon receipt of a (Re)Association Request frame during initial mobility domain association.

- **FT-INIT-AUTH:** This state is entered upon receipt of an indication that initial association is invoked.
- **FT-INIT-GET-R1_SA:** This state is entered when the R1KH determines that a new key hierarchy is required.
- **FT-INIT-R1_SA:** This state is entered on receiving the PMK-R1-SA from the R0KH and when rekeying the PTK.
- **FT-PMK-R1-SA-RECD:** This state is entered on receiving the PMK-R1-SA from the R0KH. An FT Authenticate response is sent in this state. This state then calculates the PTK and delivers the key to the MAC.
- **FT-PTK-INIT-DONE:** This state is entered on successful validation of the fourth EAPOL-Key frame. In this state, keys are provided to the MAC.
- **FT-PTK-CALC-NEGOTIATING:** This state is entered when a second EAPOL-Key frame is received.
- **FT-PTK-CALC-NEGOTIATING3:** This state is entered on successful validation of the second EAPOL-Key frame. In this state, the third EAPOL-Key frame is sent.
- **FT-PTK-START:** This state is entered when the PMK-R1-SA is present. This state is the beginning of the 4-way handshake to derive a fresh PTK.
- **FT-RV-HANDSHAKE-NEGOTIATING:** This state is entered when an FT resource request is received. The FT resource response is sent.
- **R1-START:** This is the start of the R1KH state machine.
- **SKIP-EAP:** This state is entered after successful completion of the FT protocol. In this state, the EAPOL state machine is triggered to open the IEEE 802.1X port.

13.9.3.3 R1KH state machine variables

The following list summarizes the variables used by the R1KH state machine:

- *Init* – This variable is set to true to initialize the R1KH the state machine.
- *EAPOLKeyReceived* – This variable is set to true when an EAPOL-Key frame is received.
- *K* – This variable is one of the values of the Key Type bit in the EAPOL-Key frame received and is either Pairwise or Group.
- *MIC-Verified* – This variable is set to true when the message authentication code integrity check passes.
- *Pairwise* – This variable is one of the values of the Key Type bit in the EAPOL-Key frame.
- *PMK-R1-SA* – This variable is set to true when a valid PMK-R1-SA is present at the R1KH.
- *PTK-RekeyRequest* – This variable is set to true when a PTK rekey request is received.
- *Reassocdeadlinetimerexp* – This variable contains the reassociation deadline timer value.
- *ReassocdeadlinetimerexpEvt* – This variable is set to true when the reassociation deadline timer expires.
- *Request* – This variable is the value of the Request bit in the Key Information field in the EAPOL-Key frame.
- *Resv-flow* – This variable is set to true when an indication of an FT resource request protocol is received.
- *R0-TimeoutEvt* – This variable is set to true when the timeout for R0KH authentication expires (e.g., when the EAP authentication session timeout expires).
- *TimeoutCtr* – This variable contains the number of successive timeouts waiting for protocol responses.
- *TimeoutEvt* – This variable is set to true when a timeout for receiving EAPOL-Key response expires.

13.9.3.4 R1KH state machine procedures

The following list summarizes the procedure used by the R1KH state machine:

- **Calc-FT-PTK()** – This procedure calculates the PTK.

13.9.4 S0KH state machine

13.9.4.1 General

There is one S0KH state machine within the Supplicant, defined in Figure 13-16, which incorporates the FT initial association and key management.

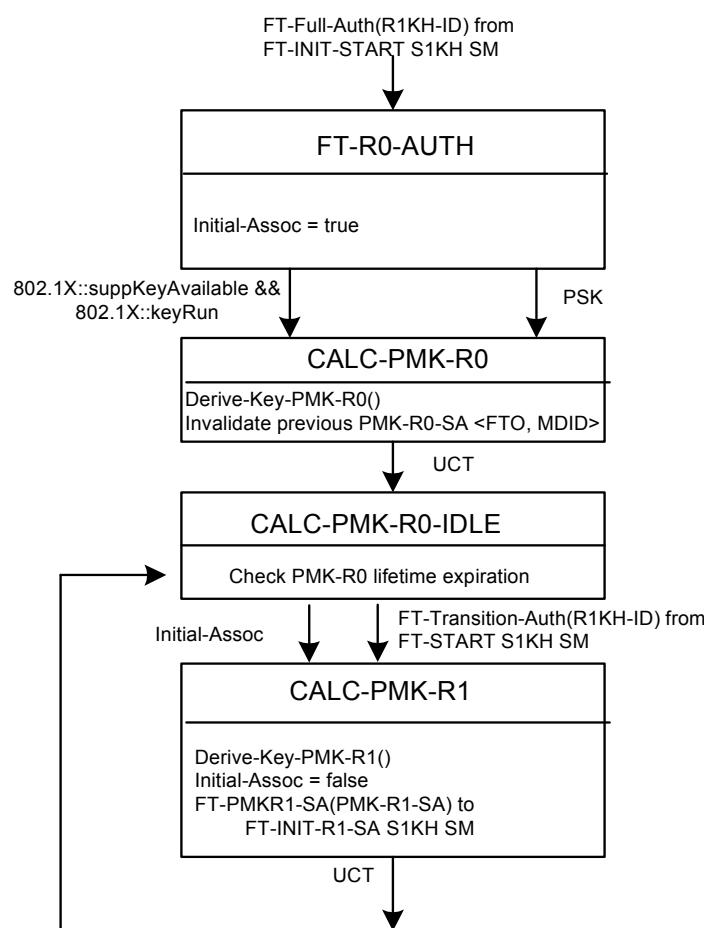

Figure 13-16—S0KH state machine

13.9.4.2 S0KH state machine states

The following list summarizes the states of the S0KH state machine:

- **CALC-PMK-R0**: This state is entered after the key is received, either from the EAP authentication or from the PSK.
- **CALC-PMK-R0-IDLE**: This state is entered after the PMK-R0 has been calculated and either continues with initial association or waits for requests from an S1KH for a PMK-R1.

- **CALC-PMK-R1:** For FT initial association, this state is entered as an unconditional transfer. For FT protocols, this state is entered through the event from the S1KH state machine. In this state, the PMK-R1 is sent to the S1KH.
- **FT-R0-AUTH:** This state is entered when the FT-Full-Auth event occurs during initial association in the S1KH state machine. The S1KH state machine sends this event when it determines that a new PMK-R0 is needed.

13.9.4.3 S0KH state machine variables

The following list summarizes the variables used by the S0KH state machine:

- *Initial-Assoc* – This variable is used to indicate whether the current authentication is the initial association, in order to trigger the initial derivation of PMK-R1.
- *PSK* – This variable is set to true when authentication is performed by use of a preshared key.

13.9.4.4 S0KH state machine procedures

The following list summarizes the procedures used by the S0KH state machine:

- **Derive-Key-PMK-R0()** – This procedure derives the PMK-R0 and PMKR0Name and creates PMK-R0 security association.
- **Derive-Key-PMK-R1 (R1KH-ID)** – This procedure derives the PMK-R1 and PMKR1Name from PMK-R0 for the indicated R1KH and creates PMK-R1 security association.

13.9.5 S1KH state machine

13.9.5.1 General

The S1KH state machine includes functions for fast BSS transitions, including initial association. The S1KH state machine and other portions of the SME are defined in Figure 13-17 and Figure 13-18 and consist of a set of states that handle FT initial association, PTK handshake and session establishment, resource requests, cleanup, and teardown. This state machine interacts with the S0KH state machine to generate a fresh key hierarchy.

13.9.5.2 S1KH state machine states

The following list summarizes the states of the S1KH state machine:

- **DISCONNECT:** This state is entered when the current session expires.
- **FT-AIR-REQUEST:** This state is entered when it is determined that an over-the-air FT method is to be executed. This state sends the Authentication-Request frame over the air.
- **FT-DONE:** This state is entered when a Reassociation Response frame is received.
- **FT-DS-REQUEST:** This state is entered when it is determined that an over-the-DS FT method is to be executed. This state sends the Authentication-Request frame over the DS.
- **FT-INIT:** This state is entered when an FT method is initiated.
- **FT-INIT-ASSOC:** This state is entered when authentication for initial mobility domain association has been completed.
- **FT-INIT-AUTH:** This state is entered when an FT initial association event is initiated.
- **FT-INIT-START:** This state is entered when association for initial mobility domain association has been completed.
- **FT-INIT-R1-SA:** This state is entered on receiving the PMK-R1-SA from the S0KH and when the Authenticator is starting PTK rekeying by sending out EAPOL-Key frame 1.

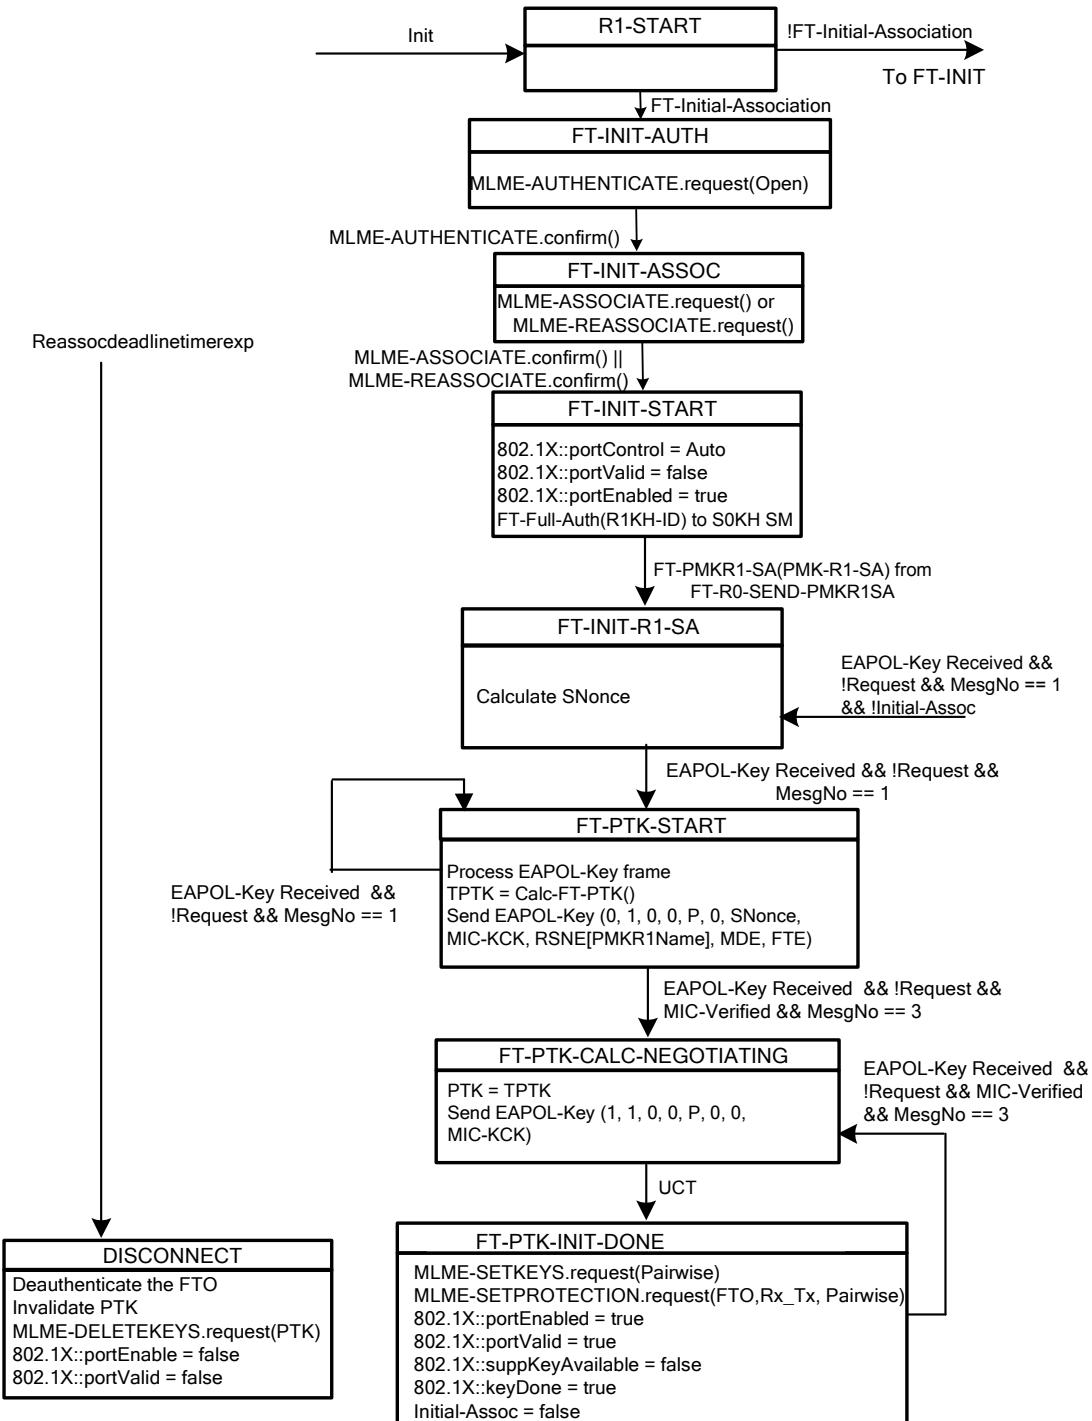

Figure 13-17—S1KH state machine, including portions of the SME (part 1)

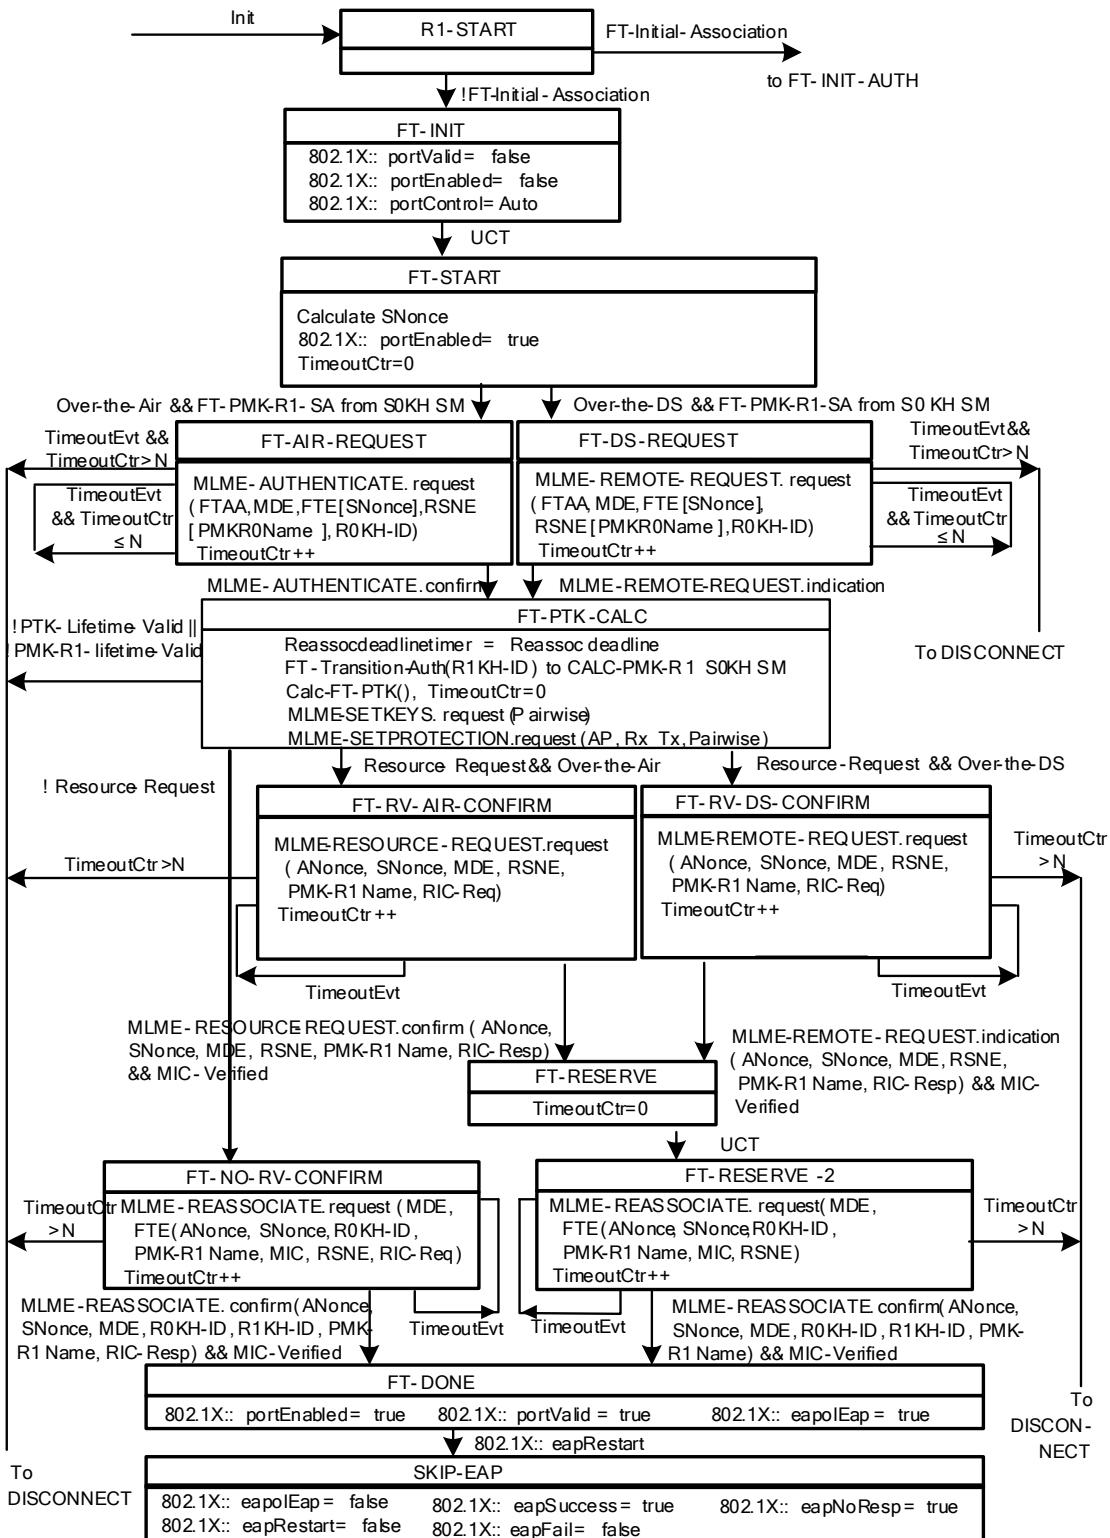

Figure 13-18—S1KH state machine, including portions of the SME (part 2)

- **FT-NO-RV-CONFIRM:** This state is entered when performing FT protocol (i.e., not the FT resource request protocol). This state is entered for both over-the-air and over-the-DS processing. This state sends the Reassociation Request frame.
- **FT-PTK-CALC:** This state is entered when the over-the-air Authentication-Response frame is received if an over-the-air Authentication-Request frame was sent or when over-the-DS FT Response frame is received if an over-the-DS FT Request frame was sent. The PTK is calculated and installed in the MAC.
- **FT-PTK-INIT-DONE:** This state is entered after sending the fourth EAPOL-Key frame. This state establishes the PTK into the MAC.
- **FT-PTK-CALC-NEGOTIATING:** This state is entered when a valid, third EAPOL-Key frame is received. This state sends the fourth EAPOL-Key frame.
- **FT-PTK-START:** This state is entered to derive a new PTK when the PMK-R1-SA is present and when the EAPOL-Key 4-way handshake message 1 is received. This state sends the EAPOL-Key 4-way handshake message 2.
- **FT-RESERVE:** This state is entered when the over-the-air Authentication-Ack frame is received if an over-the-air Authentication-Confirm frame was sent or when over-the-DS FT Ack frame is received if an over-the-DS FT Confirm frame was sent.
- **FT-RESERVE-2:** The Reassociation Request frame is sent in this state after completion of FT resource request.
- **FT-RV-AIR-CONFIRM:** This state is entered for over-the-air FT resource request protocol processing. The Authentication-Confirm frame containing the FT resource request is sent.
- **FT-RV-DS-CONFIRM:** This state is entered for over-the-DS FT resource request protocol processing. The Authentication-Confirm frame containing the FT resource request is sent.
- **FT-START:** This state is entered when all FT parameters are validated and FT needs to be initiated.
- **R1-START:** This is the start of the S1KH state machine.
- **SKIP-EAP:** This state is entered after successful completion of the FT protocol. In this state, the EAPOL state machine is triggered to open the IEEE 802.1X port.

13.9.5.3 S1KH state machine variables

The following list summarizes the variables used by the S1KH state machine:

- *EAPOLKeyReceived* – This variable is set to true when an EAPOL-Key frame is received.
- *FT-Initial-Association* – This variable is set to true when the S1KH is performing an initial association.
- *Init* – This variable is set to true to initialize the S1KH state machine. In addition, this variable is used to restart the state machine when transitioning to a new AP.
- *MsgNo* – In conjunction with *EAPOLKeyReceived*, this variable indicates which message in the 4-way handshake has been received.
- *MIC-Verified* – This variable is set to true when the message authentication integrity check is valid.
- *N* – This variable contains the limit of timeout events before considering the transition a failure.
- *Over-the-Air* – This variable is set to true when the FT protocol is to be exchanged over the air. Note that both *Over-the-Air* and *Over-the-DS* cannot be equal to true at the same time.
- *Over-the-DS* – This variable is set to true when the FT protocol is to be exchanged over the DS. Note that both *Over-the-Air* or *Over-the-DS* cannot be equal to true at the same time.
- *PMK-R1-Lifetime-Valid* – This variable is set to true when the PMK-R1 lifetime is valid.
- *PTK-Lifetime-Valid* – This variable is set to true when the PTK lifetime is valid.
- *Reassocdeadlinetimer* – This variable contains the reassociation deadline timer value.

- *ReassocdeadlinetimerExp* – This variable is set to true when the reassociation deadline timer expires.
- *Resource-request* – This variable is set to true when the FT resource request protocol is to be executed.
- *TimeoutCtr* – This variable contains the number of successive timeouts waiting for protocol responses.
- *TimeoutEvt* – This variable is set to true when a timeout event occurs.
- *TPTK* – This variable contains the newly calculated PTK, which is installed after receipt of message 3 of the 4-way handshake.

13.9.5.4 S1KH state machine procedures

The following list summarizes the procedure used by the S1KH state machine:

- **Calc-FT-PTK()** – This procedure calculates the PTK.

13.10 Remote request broker (RRB) communication

13.10.1 Overview

The RRB mechanism allows the FTO to communicate with a target AP through the FTO’s existing association (with the current AP). The FTO transmits an FT Action frame (including the address of the FTO and the BSSID of the target AP) to the current AP. The current AP includes the contents of the FT Action frame (Request or Confirm) inside a Remote Request frame and transmits it to the target AP over the DS. The target AP processes the remote request and responds to the FTO by sending an FT Action frame (Response or Acknowledgment) through the current AP.

The SME of the FTO initiates an exchange with a target AP by issuing an MLME-REMOTE-REQUEST.request primitive with parameters including the contents of the FT Action frame to be sent. The MAC of the FTO transmits this Action frame. When the MAC of the current AP receives an FT Action frame, it passes it to the RRB by use of an MLME-REMOTE-REQUEST.indication primitive, with parameters including the contents of the received Action frame.

When the RRB of the current AP has received a response from the target AP, it uses the MLME-REMOTE-REQUEST.request primitive to send the response, as an FT Action frame, to the requesting FTO. The MAC of the current AP transmits this Action frame. When the MAC of the FTO receives an FT Action frame, the MAC passes the Action frame to the SME by use of an MLME-REMOTE-REQUEST.indication primitive, with parameters including the contents of the received Action frame.

13.10.2 Remote request broker (RRB)

The RRB resides in the SME on the APs and acts as a forwarding agent (at the current AP) and termination point (at the target AP) for protocol messages over the DS.

The RRB allows APs that are part of the same mobility domain to exchange information over the DS. APs that advertise the same MDID shall be reachable over the DS and support the over-the-DS communication.

As a termination point, when the RRB at the target AP receives a request frame from the current AP, it interacts with the MAC and other parts of the SME to process the request and respond with a Remote Response frame, through the RRB on the current AP, back to the requesting FTO.

As a forwarding agent, when the RRB at the current AP receives a request from an FTO directed to another AP in the same mobility domain, the current AP forwards the request to that target AP. The RRB on the

current AP converts Action frames into Remote Request frames and converts Remote Response frames into Action frames.

The target AP and the current AP need to reside in the same mobility domain to successfully exchange Remote Request frames. The RRB on the current AP shall transmit Remote Request frames to the target AP based on the BSSID of the target AP (supplied in the FT Action frames) using the same procedures as preauthentication, as described in 12.6.10.2.

The message flow for a resource request over the DS is given in Figure 13-19. The FTO indicates the destination target AP BSSID as part of the FT Action frame. The RRB on the current AP encapsulates the FT Action frame and supplies the current AP BSSID in the Remote Request frame.

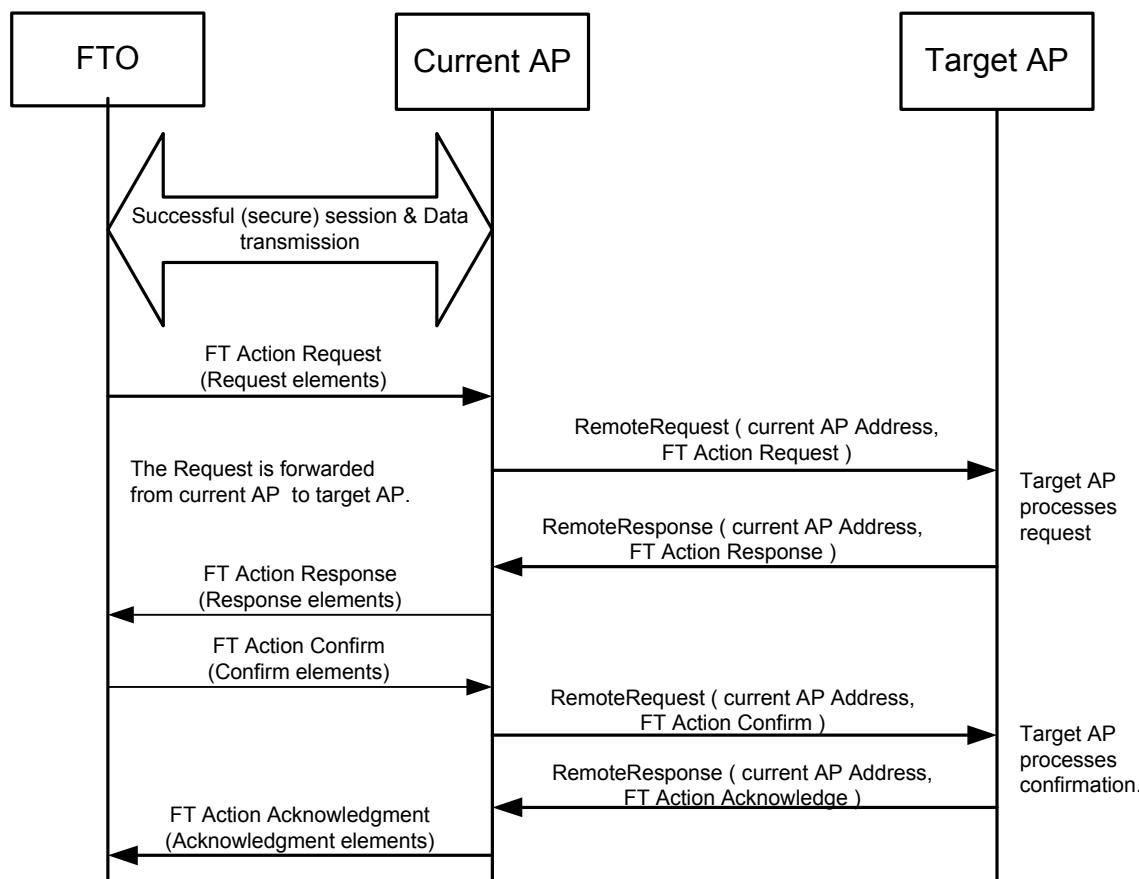

Figure 13-19—Sample message flow for over-the-DS resource request

13.10.3 Remote Request/Response frame definition

This subclause defines a mechanism to transport the remote request and remote response between the current AP and the target AP. Any other mechanism may be used.

The Remote Request frame is transmitted over the DS from the current AP to the target AP. The Payload for the Remote Request/Response frame is given in Table 13-2. Remote Request/Response frames shall use an Ethertype of 89-0d, as specified in Annex H. The Remote Request/Response frame contains Version, Type, and Length fields, along with the AP Address.

Table 13-2—Remote Request/Response Payload format

| Size | Information |
|----------|------------------|
| 1 | FT Packet Type |
| 2 | FT Action Length |
| 6 | AP Address |
| Variable | FT Action Frame |

The FT Packet Type field shall be set to 0 for remote request and to 1 for remote response.

The FT Action Length field shall be set to an unsigned number representing the length in octets of the FT Action Frame field, following the bit ordering conventions of 9.2.2.

The AP Address field shall be set to the BSSID of the current AP. The target AP shall use this address as the destination address when sending the Remote Response frame as a response to the Remote Request.

The FT Action Frame field shall be set to the contents of the FT Action frame, from the Category field to the end of the Action frame body.

13.11 Resource request procedures

13.11.1 General

When using the resource request procedure, the FTO has the option to request a resource allocation at the target AP. To request resources, the FTO creates a resource information container (RIC) and inserts it in an appropriate request message to the target AP. The request message is sent to the target AP either directly (over the air), or via the current AP (over the DS), according to the FT procedures described in 13.5 and 13.6. In an RSNA, resource requests and responses are exchanged only after the establishment of the PTK and are protected by MICs.

The RIC contains a complete list of resources requested by the FTO. An AP that receives a resource request from an FTO shall discard any previous resource request from that FTO. In an RSN, this resource request shall first be authenticated by the AP through checking of the MIC before the AP discards any previous resource request.

If an FTO is performing a fast BSS transition according to the FT protocol, described in 13.5, it shall generate a RIC and process the RIC-Response according to the procedures of 13.11.3.1, performing the exchange in the Reassociation Request/Response frames.

If an FTO is performing a fast BSS transition according to the FT resource request protocol, described in 13.6, it shall generate a RIC and process the RIC-Response according to the procedures of 13.11.3.1, performing the exchange in the Authentication-Confirm/Authentication-Ack frames (over the air) or FT Confirm/FT Ack frames (over the DS).

13.11.2 Resource information container (RIC)

The RIC refers to a collection of elements that are used to express a resource request or response.

When used in making a request, a RIC has one or more Resource Requests, as shown in Figure 13-20.

| | | |
|------------------|------------------|------------------|
| Resource Request | Resource Request | Resource Request |
|------------------|------------------|------------------|

Figure 13-20—RIC-Request format

Each Resource Request consists of an RDE followed by one or more alternative Resource Descriptors. An example of a Resource Request is shown in Figure 13-21.

| | |
|-----|---------------------|
| RDE | Resource Descriptor |
|-----|---------------------|

Figure 13-21—Resource Request format

Each Resource Descriptor consists of one or more elements. The possible Resource Descriptors that may appear in a RIC, and the elements that they contain, are given in Table 13-3.

Table 13-3—Resource types and resource descriptor definitions

| Resource type | Resource Descriptor definition | Notes |
|----------------------|---|---|
| 802.11 QoS | <p>In a request: TSPEC (see 9.4.2.30), followed by zero or more TCLAS (see 9.4.2.31), followed by zero or one TCLAS Processing (see 9.4.2.33), followed by zero or one Expedited Bandwidth Request elements (see 9.4.2.94).</p> <p>In a response: a TSPEC element (see 9.4.2.30), followed by zero or one Schedule elements (see 9.4.2.34), followed by zero or more Delay elements (see 9.4.2.32), followed by other optional elements as specified in 11.4.</p> | May be sent by a QoS STA that is an FTO to a QoS AP. Definition of TSPEC elements shall be as given in 11.4. Definition of TCLAS, TCLAS Processing, Expedited Bandwidth Request, and Schedule elements, and the rules for including them in requests and responses, shall be as given in 11.4. Resource request procedures shall be as given in 11.4. |
| Block Ack Parameters | <p>In a request: RIC Descriptor (see 9.4.2.51), containing a Resource Type field identifying Block Ack.</p> <p>In a response: RIC Descriptor (see 9.4.2.51), containing a Resource Type field identifying Block Ack.</p> | Resource request procedures shall be as given in 11.5. |
| Vendor Specific | RDE is followed by any vendor-specific elements required to specify this resource. | |

If there are multiple Resource Descriptors, then they are treated as choices by the target AP. The AP attempts to allocate whatever is specified in the first Resource Descriptor; if this fails, the AP attempts to allocate whatever is specified in the next Resource Descriptor instead, and so on until a successful allocation or the AP reaches the end of the Resource Descriptor list. Thus, an OR relationship exists between Resource Descriptors that follow an RDE, with the Resource Descriptors appearing in order of preference.

An example of a Resource Request consisting of two alternative Resource Descriptors is shown in Figure 13-22.

| | | |
|-----|---------------------|---------------------|
| RDE | Resource Descriptor | Resource Descriptor |
|-----|---------------------|---------------------|

Figure 13-22—Resource Request example #1

For example, when the resource being requested is QoS for downstream traffic, a TSPEC element may be followed by one or more TCLAS elements and, when multiple TCLAS elements are present, a TCLAS Processing element and an Expedited Bandwidth Request (EBR) element. Such an example Resource Request with two alternative TSPECs, the second of which has an EBR, is shown in Figure 13-23.

| | | | | | | | | | |
|-----|-------|-------|-------|------------------|-------|-------|-------|------------------|-----|
| RDE | TSPEC | TCLAS | TCLAS | TCLAS Processing | TSPEC | TCLAS | TCLAS | TCLAS Processing | EBR |
|-----|-------|-------|-------|------------------|-------|-------|-------|------------------|-----|

Figure 13-23—Resource Request example #2

An example of a RIC with two resource requests, each with a single TSPEC, is given in Figure 13-24.

| | | | |
|-----|-------|-----|-------|
| RDE | TSPEC | RDE | TSPEC |
|-----|-------|-----|-------|

Figure 13-24—RIC-Request example #1

An example of a RIC with one resource request, with a choice of two TSPECs, is given in Figure 13-25. This indicates that the target AP can select one of the two TSPECs.

| | | |
|-----|-------|-------|
| RDE | TSPEC | TSPEC |
|-----|-------|-------|

Figure 13-25—RIC-Request example #2

An example of a RIC with a RIC Descriptor is given in Figure 13-26. The target AP can acknowledge if the resource specified in the RIC Descriptor is available.

| | |
|-----|---------------------------|
| RDE | RIC Descriptor (BlockAck) |
|-----|---------------------------|

Figure 13-26—RIC-Request example #3

When sent by an AP in response to a RIC-Request, the RIC-Response consists of a list of one or more Resource Responses including one response for each of the Resource Requests that was contained in the RIC-Request. The basic format of a RIC-Response is shown in Figure 13-27.

| | | |
|-------------------|-------------------|-------------------|
| Resource Response | Resource Response | Resource Response |
|-------------------|-------------------|-------------------|

Figure 13-27—RIC-Response format

Each Resource Response consists of an RDE with the RDE identifier matching the RDE identifier in the request, in the same order as the RDEs appeared in the request. The RDE is followed by zero or one Resource Descriptors. If the request was not successful (as indicated in the RDE status), then the AP may include a suggestion that could have been successful. If the resource request was successful, then the particular Resource Descriptor (of the alternatives given by the FTO) is included in the response, as modified by the AP during the processing of the resource request. For example, when the resource being requested is QoS for upstream traffic, the TSPEC element may be followed by a Schedule element.

An example of a RIC-Response with two QoS resource responses, each with a single TSPEC and Schedule element, is given in Figure 13-28.

| | | | | | |
|-----|-------|----------|-----|-------|----------|
| RDE | TSPEC | Schedule | RDE | TSPEC | Schedule |
|-----|-------|----------|-----|-------|----------|

Figure 13-28—Example QoS RIC-Response

13.11.3 Creation and handling of a resource request

13.11.3.1 FTO procedures

The resource request enables an FTO to request resources based on specified Resource Descriptors (e.g., TSPECs) before or at the time the FTO associates with the target AP. In using TSPECs for requesting QoS resources, the TSPECs in the request need not belong to only active TSs; the FTO can send TSPECs for any TS that it intends to use after the transition and request the same resources that would be requested by a later ADDTS exchange. For each resource, the FTO may provide the AP with a choice of Resource Descriptors in order of preference, any one of which meets the needs of the application.

The FTO shall construct the RIC with a number of Resource Requests, each delineated by an RDE.

The FTO shall indicate the resources required at the target AP. For QoS resources, each TS shall be requested by a separate RDE and associated TSPEC(s). The RDE Identifier field in the RDE shall be an arbitrary value chosen by the FTO that uniquely identifies the RDE within the RIC. The Status Code field shall be set to SUCCESS, and the Resource Count field shall be set to the number of alternative Resource Descriptors that follow.

Following each RDE, the FTO shall include one or more Resource Descriptors that define the resources required for this TS. When multiple TSPECs follow an RDE as part of a single QoS resource request, a logical “OR” relationship exists between them, and at most one of these TSPECs shall be accepted by the AP. The FTO shall order the Resource Descriptors in decreasing order of preference.

In generating the RDE for QoS resources for a TS, the procedures of 11.4 shall be followed for the generation of TSPECs and inclusion of TCLAS, TCLAS Processing, and Expedited Bandwidth Request elements. If the TS is a downstream flow, then the RDE may also include one or more TCLAS element(s) (defined in 9.4.2.31) and a TCLAS Processing element (defined in 9.4.2.33) if multiple TCLAS elements are included, and an optional Expedited Bandwidth Request (EBR) element, defined in 9.4.2.94. If present, the TCLAS shall appear after the corresponding TSPEC. If present, an EBR element shall appear after the corresponding TSPEC, TCLAS, and TCLAS Processing elements of the TSPEC.

A resource request is considered successful if the status code SUCCESS is returned in each RDE.

If the frame containing the response to the resource request contains a status code other than SUCCESS, the FTO considers that the request has failed and that no resources are being held at the target AP.

The response from the target AP contains a RIC-Response, with the RDEs in the response indicating which resources were considered by the target AP and the setting of the status code indicating which Resource Descriptors were accepted by the AP.

The RDE Identifier field in the RDE enables the FTO to match the response with the RDE in the request. The value of the Status Code field is interpreted as follows:

- Status code = SUCCESS indicates that the request has been accepted. The RDE may be followed by the Resource Descriptor that was accepted.
- Status code = not SUCCESS (one of the values from 9.4.1.9) indicates that the resources could not be accepted. The RDE may be followed by a suggested Resource Descriptor that could have been accepted.

A response to a successful resource request (other than in a Reassociation Request frame) may contain a reassociation deadline. If the FTO does not initiate a Reassociation Request frame with the target AP within the reassociation deadline (if appropriate), then the AP releases resources held for that FTO.

13.11.3.2 AP procedures

When a RIC appears in a request message, the AP shall check its ability to allocate one resource for each RDE in the RIC in the order appearing in the RIC. In a Reassociation Request frame, the QoS Capability element shall be processed prior to the QoS resource requests in the RIC.

The behavior of the AP shall be identical to that described in the flowchart in Figure 13-29.

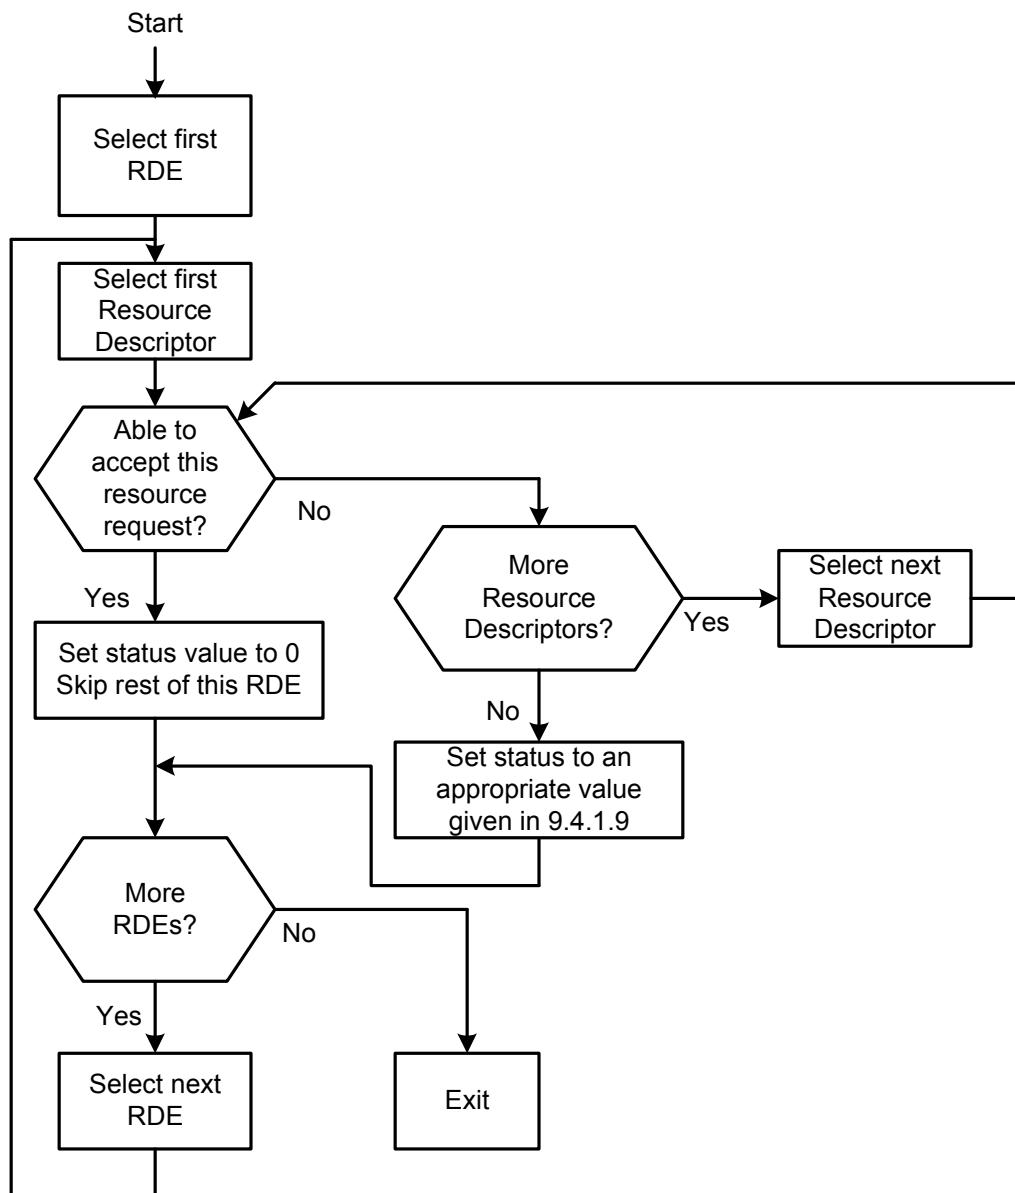

Figure 13-29—Overview of RIC processing at an AP

As shown in Figure 13-29, the Resource Descriptors are examined by the AP in the order presented, and the first that could have been allocated is accepted. Thus the preference ordering by the FTO is honored.

The target AP's SME examines the resource requests in the RIC. For requests that require processing by the MAC sublayer, the SME generates an MLME-RESOURCE-REQUEST-LOCAL.request primitive. The MAC shall respond with MLME-RESOURCE-REQUEST-LOCAL.confirm primitive that indicates whether the MAC has accepted the resource request. The SME may also send these resource requests to an external entity such as a backend QoS module for its consideration; these procedures are beyond the scope of this standard. The acceptance of a TSPEC by the target AP results in the resource allocation for a TS at the target AP.

In response to a RIC-Request, the AP shall construct a RIC-Response. The RIC-Response shall contain one RDE for each RDE in the RIC-Request. The RDEs shall be in the same order as in the request, and the RDE Identifier field in each RDE shall be the value of the RDE Identifier field in the corresponding RDE in the request. The Status Code field in the RDE shall be set according to the result of the allocation request as follows:

- Status code = SUCCESS indicates that the resource request has been accepted. The RDE shall also be followed by the Resource Descriptor that was accepted.
- Status code = not SUCCESS indicates that the resources could not be accepted. The Status Code field contains a value from 9.4.1.9 indicating the reason for the failure. In this case, the AP may include a single Resource Descriptor following the RDE indicating a suggested resource that could have been accepted. The Resource Count field shall be set to 0 or 1 depending whether the suggested Resource Descriptor is attached. A not SUCCESS status code in an RDE shall not cause a not SUCCESS status code in the frame containing the RIC.

If the resource request included QoS resources and is successful, then the procedures for handling of TSPEC, TCLAS, TCLAS Processing and Expedited Bandwidth Request elements shall be as specified in 11.4, and the AP shall place the TSs into the accepted state. The RIC-Response shall contain the updated accepted TSPEC. Each RDE may also include a Schedule element (as defined in 9.4.2.34) after the accepted TSPEC. Upon reassociation, AP shall move all of the TSs from the accepted state into the active state.

If the FTO does not invoke a reassociation within the reassociation deadline, then the TSs that had been accepted shall become inactive, and the resources shall be released. At the point that the FTO reassociates with the target AP (within the reassociation deadline, if appropriate), the TSs are put into the active state. This may be immediate if the RIC-Request was part of a Reassociation Request frame.

14. MLME mesh procedures

14.1 Mesh STA dependencies

When `dot11MeshActivated` is true, the STA is a mesh STA.

When `dot11MeshActivated` is true, following MIB attributes shall be true.

- `dot11QoSOptionImplemented`
- `dot11ExtendedChannelSwitchActivated` (only when `dot11SpectrumManagementRequired` is true)

When `dot11MeshActivated` is true, following MIB attributes shall be false.

- `dot11OCBActivated`
- `dot11FastBSSTransitionActivated`

A mesh STA does not support functionalities that depend on AP or are only available in an infrastructure BSS, such as HCCA, traffic specifications (TSPECs), traffic stream (TS) management, admission control, automatic power save delivery (APSD), direct-link setup (DLS), or tunneled direct-link setup (TDLS).

An HT mesh STA does not support PSMP, STBC, or PCO.

When `dot11DMGOptionImplemented` is true, `dot11MeshActivated` shall be false.

14.2 Mesh discovery

14.2.1 General

A mesh STA shall perform either active scanning or passive scanning to discover an operating mesh BSS using the `MLME-SCAN.request` primitive (see 6.3.3). A mesh profile, a set of parameters identifying the mesh BSS configuration, is also obtained through the scanning process, and it is used to determine the scanning mesh STA's active mesh profile. Based on the result of the scan, the mesh STA may establish a new mesh BSS or become a member of the existing mesh BSS, using the `START` primitive (see 6.3.11). The `MLME-START.request` primitive triggers beaconing that facilitates the discovery of the mesh STA by the neighbor mesh STAs. A mesh STA that becomes a member of a mesh BSS should establish a mesh peering with one or more neighbor mesh STAs that are in the same mesh BSS.

14.2.2 Mesh identifier

The Mesh ID is an identifier of an MBSS. The Mesh ID may be installed in mesh capable devices by a variety of means that are beyond the scope of this standard. For example, the Mesh ID might be set by the user, e.g., “Mike’s Mesh.” A mesh STA shall include the Mesh ID element (see 9.4.2.99) in its Beacon and Probe Response frames, in order to advertise its identity. The mesh STA shall also include the Mesh ID element in its Mesh Peering Open frames, Mesh Peering Confirm frames, and Mesh Peering Close frames.

The mesh STA shall set the SSID element (see 9.4.2.2) in Beacon, Probe Request, and Probe Response frames to the wildcard SSID.

NOTE—The wildcard SSID is used to notify nonmesh STAs that the mesh STA is neither a part of an infrastructure BSS nor an IBSS, so that the nonmesh STAs do not try to join the mesh BSS.

14.2.3 Mesh profile

A mesh profile is a set of parameters that specifies the attributes of a mesh BSS. A mesh profile consists of the following:

- a) A Mesh ID—specified by dot11MeshID
- b) A path selection protocol identifier—specified by dot11MeshActivePathSelectionProtocol
- c) A path selection metric identifier—specified by dot11MeshActivePathSelectionMetric
- d) A congestion control mode identifier—specified by dot11MeshActiveCongestionControlMode
- e) A synchronization method identifier—specified by dot11MeshActiveSynchronizationMethod
- f) An authentication protocol identifier—specified by dot11MeshActiveAuthenticationProtocol

In a mesh BSS all mesh STAs use the same mesh profile. Two mesh profiles are considered to be the same if all of their parameters match.

Before establishing a mesh BSS or becoming a member of a mesh BSS, a mesh STA shall configure one mesh profile. The mesh STA shall not change its mesh profile unless it leaves the mesh BSS of which it is a member. When the mesh STA leaves the mesh BSS of which it is a member, it should explicitly close all of its active mesh peerings using Mesh Peering Close frames (see 14.3.8) and shall discard all session information obtained while the mesh profile was active, such as local forwarding information, security associations (and related keys), etc. The MLME receives the mesh STA's mesh profile from the SME upon receipt of the MLME-START.request primitive.

The mesh profile is signaled by means of the Mesh ID element and the Mesh Configuration element. The mesh profile is included in the Beacon and Probe Response frames, so that the mesh profile can be obtained by its neighbor mesh STAs through scanning. Mesh Peering Open and Mesh Peering Confirm frames also contain a mesh profile.

14.2.4 Mesh STA configuration

The mesh STA configuration consists of the mesh profile (see 14.2.3), the Supported Rates and BSS Membership Selectors element, the Extended Supported Rates and BSS Membership Selectors element, the HT Operations element (if present), and the VHT Operations element (if present).

Mesh STA configurations are identical if the following conditions hold:

- The mesh profiles are identical.
- The BSSBasicRateSet parameter of the MLME-START.request is identical to the basic rate set indicated by the Supported Rates and BSS Membership Selectors element and Extended Supported Rates and BSS Membership Selectors element, if present, received in the MLME-MESHPEERINGMANAGEMENT.indication.
- For HT mesh STAs, the Basic HT-MCS Set field of the HT Operation parameter of the MLME-START.request is identical to the HT Operation element received in the MLME-MESHPEERINGMANAGEMENT.indication.
- For VHT mesh STAs, the Basic VHT-MCS and NSS fields in the VHT Operation element of the MLME-START.request are identical to the Basic VHT-MCS and NSS fields in the VHT Operation element received in the MLME-MESHPEERINGMANAGEMENT.indication.

14.2.5 Supplemental information for the mesh discovery

A mesh STA shall signal whether it is able to establish additional mesh peerings. A mesh STA signals its ability to establish additional mesh peerings by setting the Accepting Additional Mesh Peerings subfield in the Mesh Capability field in the Mesh Configuration element to 1 (see 9.4.2.98.8).

The mesh STA sets the Accepting Additional Mesh Peerings subfield in the Mesh Capability field in the Mesh Configuration element to 0 when it is not able to accept new mesh peerings. This parameter is dynamically controlled by the SME and given to the MLME by dot11MeshAcceptingAdditionalPeerings.

NOTE—This control is driven by internal policies. When the Accepting Additional Mesh Peering subfield is 1, the mesh STA is assumed to have sufficient internal resources to accommodate more mesh peerings. The internal policy is outside the scope of this standard. For instance, a mesh STA might be configured to be able to maintain only two mesh peerings.

A mesh STA shall announce its topological information through the Mesh Formation Info field in the Mesh Configuration element. The contents of the Mesh Formation Info field shall be coded to reflect the current configuration.

14.2.6 Scanning mesh BSSs

A mesh STA shall perform active scanning or passive scanning, depending on the value of the ScanMode parameter of the MLME-SCAN.request primitive (see 11.1.4), to discover neighbor mesh STAs. Upon receipt of an MLME-SCAN.request primitive with the Mesh ID parameter set to the wildcard Mesh ID, the STA shall passively scan for any Beacon frames, or actively transmit Probe Request frames containing the wildcard Mesh ID, as appropriate, depending on the value of ScanMode. Upon completion of scanning, an MLME-SCAN.confirm primitive is issued by the MLME indicating all of the discovery information received. Further, a mesh STA shall comply with the passive scan procedure as described in 11.1.4.2 and the active scan procedure as described in 11.1.4.3.

14.2.7 Candidate peer mesh STA

When a mesh STA discovers a neighbor mesh STA through the scanning process and the discovered mesh STA is considered a candidate peer mesh STA, it may become a member of the mesh BSS of which the discovered mesh STA is a member and establish a mesh peering with the neighbor mesh STA.

The discovered neighbor mesh STA shall be considered a candidate peer mesh STA if and only if all of the following conditions are met:

- a) The mesh STA uses the same mesh profile as the received Beacon or Probe Response frame indicates for the neighbor mesh STA.

NOTE—If the scanning mesh STA has not become a member of any MBSS yet, it might simply activate the same mesh profile as the discovered neighbor mesh STA's profile to fulfill this condition.

- b) The Accepting Additional Mesh Peerings subfield in the Mesh Capability field in the received Beacon or Probe Response frame equals 1.
- c) The mesh STA supports the data rates indicated by the BSSBasicRateSet of the received Beacon or Probe Response frame.
- d) If both the scanning mesh STA and the discovered neighbor STA are HT STAs, the STA has the same value in the Basic HT-MCS Set field of the HT Operation parameter of the MLME-START.request primitive as the received Beacon or Probe Response frame indicates for the neighbor mesh STA.
- e) If both the scanning mesh STA and the discovered neighbor STA are VHT STAs, the mesh STA uses the same value for the Basic VHT-MCS And NSS Set field in its VHT Operation element as received in the Beacon or Probe Response frame from the neighbor mesh STA.
- f) If the scanning mesh STA has dot11MeshSecurityActivated equal to true and the dot11MeshActiveAuthenticationProtocol is ieee8021x (2), either the scanning mesh STA has an active connection to an AS or the discovered mesh STA has the Connected to AS subfield in the Mesh Formation field in the Mesh Configuration element equal to 1 in the received Beacon or Probe Response frame.

14.2.8 Establishing or becoming a member of a mesh BSS

The Mesh Formation Info field in the Mesh Configuration element is available to assist scanning mesh STAs in choosing the mesh BSS of which to become a member. The details of the usage of this information are beyond the scope of this standard.

NOTE—Selection of the mesh BSS of which the scanning mesh STA becomes a new member is outside the scope of this standard. That is, the mesh STA might freely select the mesh BSS of a candidate peer mesh STA of which it becomes a new member.

After the determination of the active mesh profile, the mesh STA may establish a new mesh BSS or become a new member to an existing mesh BSS.

When dot11MBCAActivated is true, the mesh STA shall perform the TBTT selection procedure described in 14.13.4.3 using TimeStamp, Local Time, Beacon Period, and Beacon Timing in the BSSDescriptionSet parameter given by the MLME-SCAN.confirm primitive, before starting its beaconing.

When dot11MCCAActivated is true, the mesh STA shall choose a DTIM interval with a duration of $2^n \times 100$ TU with n a non-negative integer less than or equal to 17.

NOTE—It is allowed that a different value for the DTIM interval is used for mesh STAs that use MCCA in an MBSS that is centrally controlled and the central authority provides a coordination of the DTIM interval of mesh STAs that use MCCA in the MBSS.

The mesh STA establishes a new mesh BSS by activating a mesh profile that is different from any mesh profile discovered during the scanning of mesh BSSs (see 14.2.6).

The mesh STA becomes a new member of an existing mesh BSS by activating the same mesh profile as received from a candidate peer mesh STA of this mesh BSS (see 14.2.6 and 14.2.7).

In either case, the mesh STA shall start beaconing using the START primitive. Upon receipt of the MLME-START.request primitive, the mesh STA shall initialize and start its TSF timer as specified by its active synchronization method as described in 14.13.2, and begin transmitting Beacon frames as described in 14.13.3.

If the mesh STA has become a new member of an existing mesh BSS, it should establish a mesh peering with one or more candidate peer mesh STAs of this mesh BSS (see 14.2.9) in order to form the MBSS.

If the mesh STA has become a new member of an existing mesh BSS, it shall adopt the BSSBasicRateSet parameter from a candidate peer mesh STA of this mesh BSS.

After establishing or becoming a member of an MBSS, the mesh STA may continue the discovery procedure described in 14.2.6 to discover other candidate peer mesh STAs.

14.2.9 Establishing mesh peerings

Mesh peerings shall be established only with candidate mesh STAs that are members of the same MBSS.

A mesh peering is established between the mesh STA and the candidate peer mesh STA after the successful completion of the mesh peering management (MPM) protocol (see 14.3) or of the authenticated mesh peering exchange (AMPE) (see 14.5). When establishing a secure mesh peering, mesh STAs authenticate each other and create a mesh PMKSA before processing the AMPE (see 14.3.3).

A candidate peer mesh STA becomes a peer mesh STA when a mesh peering is established between the two mesh STAs.

When `dot11MeshActiveSynchronizationMethod` is `neighborOffsetSynchronization` (1), a mesh STA may establish mesh peerings with up to `dot11MeshNbrOffsetMaxNeighbor` mesh STAs (see 14.13.2.2.1).

14.3 Mesh peering management (MPM)

14.3.1 General

The mesh peering management (MPM) protocol is used to establish, maintain, and close mesh peerings between mesh STAs when `dot11MeshSecurityActivated` is false. When `dot11MeshSecurityActivated` is true, the peers establish an authenticated mesh peering using the authenticated mesh peering exchange (AMPE) protocol. The AMPE protocol requires an existing mesh PMKSA. If a mesh PMKSA with the candidate peer mesh STA exists, the AMPE shall use that mesh PMKSA. If no mesh PMKSA exists, the peers shall first authenticate to establish a mesh PMKSA; see 14.5.

Figure 14-1 shows the logical flow of protocol interactions in the peering management framework.

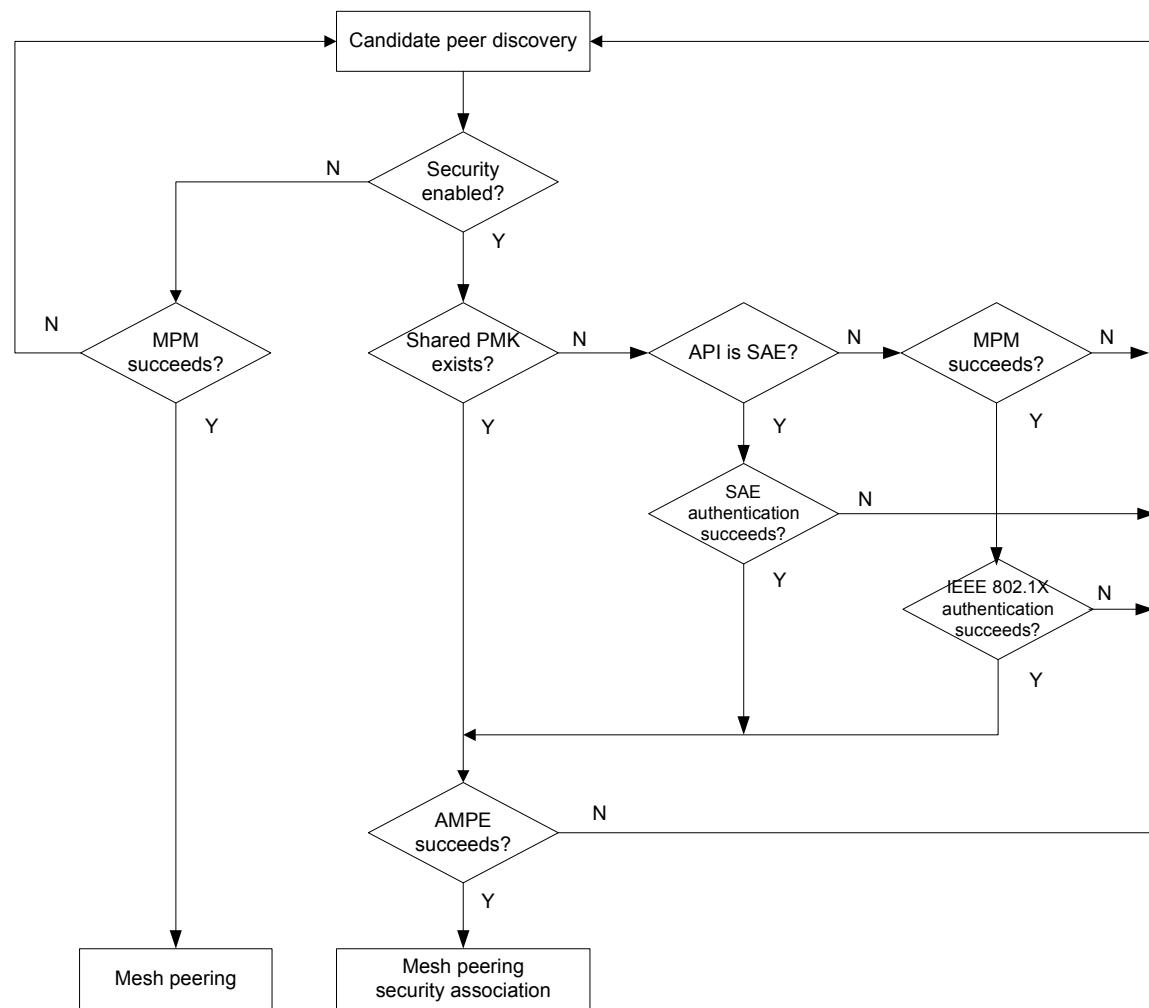

Figure 14-1—Logical flowchart of protocol interaction in the mesh peering management framework

The MPM protocol uses Mesh Peering Open frames, Mesh Peering Confirm frames, and Mesh Peering Close frames to establish, manage, and tear down a mesh peering.

The protocol succeeds in establishing a mesh peering when the following requirements are satisfied: 1) both mesh STAs have sent and received (and correctly processed) a Mesh Peering Open frame for this mesh peering; 2) both mesh STAs have sent and received (and correctly processed) a corresponding Mesh Peering Confirm frame for this mesh peering.

A mesh STA that receives and accepts a Mesh Peering Open frame (see 14.3.6.2) shall assign a unique AID among its neighbor peer mesh STAs to the transmitter of the frame. Since the AID is used in the encoding of the TIM element in the Beacon frame (see 9.4.2.6), the setting of the AID value is constrained as described in 9.4.1.8. AID 0 (zero) is reserved to indicate the presence of buffered group addressed MSDUs and MMPDUs (see 14.14.4).

14.3.2 State variable management

A mesh STA keeps an enumerated state variable (see 11.3.1) for each neighbor STA with which direct communication via the WM is needed. This state variable expresses the relationship between the local STA and a neighbor STA that varies depending on the active authentication protocol. It takes on the values shown in Table 14-1.

Table 14-1—State variables for mesh STAs

| State | Active authentication | | |
|----------------|---|--|--|
| | None | SAE | IEEE Std 802.1X |
| <i>State 1</i> | Initial start state, mesh peering not established | Initial start state, unauthenticated, mesh peering not established | Initial start state, unauthenticated, mesh peering not established |
| <i>State 2</i> | N/A | Authenticated, mesh peering not established | N/A |
| <i>State 3</i> | Mesh peering established | Authenticated, mesh peering established | Unauthenticated, mesh peering established (Pending IEEE 802.1X authentication) |
| <i>State 4</i> | N/A | N/A | Authenticated, mesh peering established |

The state transitions in accordance with the protocol interaction shown in Figure 14-1.

The current state existing between the neighbor STAs determines the IEEE 802.11 frame types that may be exchanged between that pair of STAs (see Clause 9). The allowed frame types are grouped into classes and the classes correspond to the STA state. The allowed frame types and the frame classes in each state are defined in 11.3.3.

A mesh STA shall not transmit frames other than the ones used for candidate peer mesh STA discovery, MPM, and SAE to a neighboring mesh STA until a mesh peering has been established with the mesh STA.

14.3.3 Mesh authentication

See 12.6.1.3.4.

14.3.4 Mesh peering instance controller

14.3.4.1 Overview

A mesh STA uses a mesh peering instance controller to manage all mesh peering instances.

The mesh peering instance controller performs the following functions:

- Create and delete MPM finite state machines and AMPE finite state machines
- Manage instance identifiers for each mesh peering instance
- Manage mesh TKSAAs for each mesh peering instance when dot11MeshSecurityActivated is true
- Preprocess the incoming mesh peering Management frames and pass the frames to the finite state machine with matching instance identifier
- Pass internal commands to the finite state machine with matching instance identifier

A mesh peering instance is identified by a mesh peering instance identifier. The mesh peering instance identifier is the set of localLinkID, localMAC, and peerMAC.

A mesh peering instance consists of its identifier (the localLinkID, localMAC, peerMAC), a peerLinkID (an integer generated by the peer mesh STA or candidate peer mesh STA), and the configuration and capability negotiated and agreed upon by exchanging Mesh Peering Open frames (see 9.6.16.2) and Mesh Peering Confirm frames (see 9.6.16.3). If dot11MeshSecurityActivated is true, the mesh peering instance also contains a PMKID identifying the shared PMKSA, a localNonce chosen by the mesh STA and a peerNonce chosen by the peer mesh STA or candidate peer mesh STA.

The localMAC is the MAC address of the mesh STA that is managing this mesh peering instance. The peerMAC is the MAC address of the peer mesh STA or the candidate peer mesh STA. The localLinkID is an integer generated by the mesh STA. The localLinkID shall be unique among all existing link identifiers used by the mesh STA for its MPM finite state machines. The mesh STA selects the localLinkID to provide high assurance that the same number has not been used to identify a recent MPM finite state machine. The peerLinkID is the localLinkID of the peer mesh STA or candidate peer mesh STA and is supplied in the Mesh Peering Management element (see 9.4.2.102) of the Mesh Peering Open and Mesh Peering Confirm frames.

A mesh peering instance is controlled by an MPM finite state machine (see Table 14-2 in 14.4.5) or an AMPE finite state machine (see Table 14-3 in 14.5.6.3).

14.3.4.2 Creating a new mesh peering instance

The mesh peering instance controller creates a new mesh peering instance after either of the following two events:

- The receipt of a Mesh Peering Open frame from a candidate peer mesh STA according to the rules of 14.3.5
- The receipt of an MLME-MESHPEERINGMANAGEMENT.request primitive with a Mesh Peering Open frame

A unique localLinkID shall be generated for the mesh peering instance. If the mesh peering instance is established by AMPE, a random local nonce shall also be generated.

A mesh STA may create multiple mesh peering instances to establish a peering with the same candidate peer mesh STA.

14.3.4.3 Deleting mesh peering instances

The mesh peering instance controller deletes a mesh peering instance after either:

- Expiration of a holding timer (see 14.4.4).
- The acceptance of a peer’s response to an existing request to close the peering (see 14.4.3).
- Indication from the SME that the peer mesh STA, or candidate peer mesh STA, has deauthenticated.

When the deletion occurs, the mesh TKSA that is bound to the mesh peering shall be deleted.

14.3.5 Mesh peering instance selection

The content of a mesh peering Management frame received from a candidate peer mesh STA, and the set of mesh peering instances in the mesh peering instance controller determine whether

- A new mesh peering instance is created (see 14.3.4.2); or,
- An existing mesh peering instance is updated

If `dot11MeshSecurityActivated` is true and the mesh STA shares a PMK with the candidate peer mesh STA but the Mesh Peering Protocol Identifier field in the Mesh Peering Management element of the frame indicates “mesh peering management protocol,” the frame shall be silently discarded.

If `dot11MeshSecurityActivated` is true and the mesh STA shares a PMK with the candidate peer mesh STA but either the Mesh Peering element or the MIC element are not present in the frame, the frame shall be silently discarded.

If `dot11MeshSecurityActivated` is false but the Mesh Peering Protocol Identifier field in the Mesh Peering Management element of the received frame indicates “authenticated mesh peering exchange,” the frame shall be silently discarded.

If `dot11MeshSecurityActivated` is false but either the Mesh Peering element or the MIC element is present in the frame, the frame shall be silently discarded.

If the frame contains a group address in TA or RA, it shall be silently discarded.

If the incoming mesh peering Management frame is for AMPE and the Chosen PMK from the received frame contains a PMKID that does not identify a valid mesh PMKSA, the frame shall be silently discarded.

If the mesh peering Management frame has not been silently discarded, the mesh peering instance controller attempts to locate a matching mesh peering instance identifier. A match is determined by comparing the contents of the mesh peering Management frame with each peering instance. A match is found if all of the following conditions are true:

- The transmitter’s MAC address (Address 2) is the same as the peerMAC of the mesh peering instance
- The receiver’s MAC address (Address 1) is the same as the localMAC of the mesh peering instance
- The value of the Peer Link ID field is the same as the localLinkID of the mesh peering instance

If the incoming frame is a Mesh Peering Open frame and no matching peering instance was found, a new mesh peering instance is created (and a new Mesh TSKA if `dot11MeshSecurityActivated` is true). See 14.3.4.2.

If the incoming frame is a Mesh Peering Confirm or Mesh Peering Close frame and no matching mesh peering instance is found, it shall be silently discarded.

If the incoming mesh peering Management frame is for AMPE and has not been discarded it shall be further processed as follows:

- If the PeerNonce field is present in the received frame, and the localNonce in the mesh peering instance is different from the PeerNonce field of the received frame, the frame shall be dropped.
- If the peerNonce in the mesh peering instance exists and is different from the LocalNonce field of the received frame, the frame shall be dropped.

14.3.6 Mesh peering open

14.3.6.1 Generating Mesh Peering Open frames

A Mesh Peering Open frame is generated as a result of a sendOpen() action (see 14.4.3).

The contents of the frame are described in 9.6.16.2.2.

14.3.6.2 Mesh Peering Open frame processing

The mesh STA checks that the Mesh ID element and Mesh Configuration element of the Mesh Peering Open frame is identical to its own mesh STA configuration as specified in 14.2.3 and 14.2.4. If a mismatch is found the frame shall be rejected with a reason code of MESH-CONFIGURATION-POLICY-VIOLATION and the mesh peering establishment attempt shall be terminated.

When the mesh STA has established a mesh PMKSA with the candidate peer mesh STA, the mesh peering instance controller shall silently discard the Mesh Peering Open frame in the following two conditions:

- The Mesh Peering Open frame supports MPM protocol and the negotiated active authentication is SAE, or
- The Mesh Peering Open frame supports AMPE but the PMKID in the Chosen PMK field in the Authenticated Mesh Peering Exchange element does not identify a mesh PMKSA.

If the Mesh Peering Open frame is not discarded, the mesh peering instance controller actively rejects or accepts the mesh peering open request (see 14.4). If dot11MeshAcceptingAdditionalPeerings is set to 0 the Mesh Peering Open request shall be rejected with reason code MESH-MAX-PEERS.

If the peerLinkID in the mesh peering instance has not been set, the Local Link ID field of the Mesh Peering Open request shall be copied into the peerLinkID in the mesh peering instance. If the incoming Mesh Peering Open frame is for AMPE and the peerNonce in the mesh peering instance has not been set, the LocalNonce field in the incoming Mesh Peering Open frame shall be copied into the peerNonce in the mesh peering instance.

The mesh peering open request may be rejected due to an internal reason with a reason code of MESH-PEERING-CANCELED.

NOTE—Example internal reasons to reject new mesh peering request could be the mesh STA is configured to reject mesh peering request from another specific peer mesh STA.

If the Mesh Peering Open request is rejected, the REQ_RJCT event shall be passed with the specified reason code to the protocol finite state machine to actively reject the mesh peering open request.

14.3.7 Mesh peering confirm

14.3.7.1 Generating Mesh Peering Confirm frames

A Mesh Peering Confirm frame is generated as a result of a sendConfirm() action (see 14.4.3).

The contents of the frame are described in 9.6.16.3.2.

14.3.7.2 Mesh Peering Confirm frame processing

The mesh STA shall check that the Mesh ID element and Mesh Configuration element of the Mesh Peering Confirm frame match its own mesh STA configuration as specified in 14.2.3 and 14.2.4. If a mismatch is found, the frame shall be rejected with the reason code of MESH-INCONSISTENT-PARAMETERS.

If the Mesh Peering Confirm frame is rejected, the REQ_RJCT event shall be passed with the specified reason code to the protocol finite state machine to actively reject the mesh peering confirm.

Otherwise, the mesh STA accepts the Mesh Peering Confirm frame and performs the actions described in 14.4.

If the peerLinkID in the mesh peering instance has not been set, the Local Link ID field of the Mesh Peering Confirm request shall be copied into the peerLinkID in the mesh peering instance. If the incoming Mesh Peering Confirm frame is for AMPE and the peerNonce in the mesh peering instance has not been set, the Local Nonce field in the incoming Mesh Peering Confirm frame shall be copied into the peerNonce in the mesh peering instance.

14.3.8 Mesh peering close

14.3.8.1 Generating Mesh Peering Close frames

A Mesh Peering Close frame is generated as a result of a sendClose() action (see 14.4.3).

The contents of the frame are described in 9.6.16.4.2.

When the Mesh Peering Close is generated as a result of a CNCL event, the reason code is MESH-PEERING-CANCELED. When the Mesh Peering Close is generated as a result of a CLS_ACPT event, the reason code is MESH-CLOSE-RCVD.

14.3.8.2 Mesh Peering Close frame processing

The mesh STA shall reject the Mesh Peering Close frame if the value in the Mesh ID element is not the same as the mesh STA's mesh profile. Otherwise, the mesh STA accepts the Mesh Peering Close frame and performs the actions described in 14.4.

14.4 Mesh peering management finite state machine (MPM FSM)

14.4.1 General

Each mesh peering instance, including its states and resource, are managed by a mesh peering management finite state machine (MPM FSM). The MPM FSM uses MLME primitives to control the mesh STA to send and receive mesh peering Management frames.

14.4.2 States

The MPM FSM uses the following six states:

- IDLE—IDLE state is a terminal state. In the IDLE state, the MPM FSM is ready to start a new mesh peering instance by either passively listening for an incoming Mesh Peering Open frame or actively initiating a mesh peering instance.

- OPN_SNT—In the OPN_SNT state, the finite state machine has sent a Mesh Peering Open frame and is waiting for a Mesh Peering Open frame and Mesh Peering Confirm frame from the candidate peer mesh STA.
- CNF_RCVD—In the CNF_RCVD state, the finite state machine has received a Mesh Peering Confirm frame, but has not received a Mesh Peering Open frame. The mesh STA has not sent the corresponding Mesh Peering Confirm frame yet.
- OPN_RCVD—In the OPN_RCVD state, the finite state machine has received only the Mesh Peering Open frame but not the Mesh Peering Confirm. The mesh STA has also sent a Mesh Peering Confirm frame upon receiving a Mesh Peering Open frame.
- ESTAB—In the ESTAB state, the finite state machine has received both the Mesh Peering Open and Mesh Peering Confirm frames. The mesh STA has also sent both the Mesh Peering Open frame and Mesh Peering Confirm frame. The mesh peering is established and configured for exchanging frames with the peer mesh STA in the ESTAB state.
- HOLDING—In the HOLDING state, the finite state machine is closing the mesh peering instance with the peer mesh STA or the candidate peer mesh STA.

14.4.3 Events and actions

The finite state machine uses three types of events: 1) events for state machine transitions; 2) external events generated by frame processing; and 3) events associated with internal timers.

The events for state machine transitions are as follows:

- CNCL(localLinkID, peerMAC, ReasonCode)—Used to instruct the mesh peering instance to cancel the mesh peering with the peer mesh STA. localLinkID identifies the MPM FSM for the corresponding mesh peering instance. peerMAC is the MAC address of the peer mesh entity. ReasonCode is used to inform the reason to cancel the mesh peering instance. See 14.3.8.2.
- ACTOPN(peerMAC, localLinkID)—The SME uses this event to create a new mesh peering instance to actively initiate the mesh peering establishment with the candidate peer mesh STA whose MAC address is peerMAC. localLinkID identifies the MPM FSM.

The events generated by frame processing are as follows:

- OPN_ACPT—PeeringOpen_Accept(peerMAC, peerLinkID) event indicates that a Mesh Peering Open frame meeting the correctness criteria of 14.3.6 has been received from peerMAC for the mesh peering instance identified by peerLinkID.
- OPN_RJCT—PeeringOpen_Reject(peerMAC, peerLinkID, meshConfiguration, reasonCode) event indicates that a Mesh Peering Open frame from peerMAC for the mesh peering instance identified by peerLinkID is rejected due to incomplete or erroneous mesh STA configuration (see 14.2.4), as indicated by meshConfiguration, with reasonCode being the specific reason for rejection of the Mesh Peering Open frame. See 14.3.6.2.
- CNF_ACPT—PeeringConfirm_Accept(peerMAC, localLinkID, peerLinkID) event indicates that a Mesh Peering Confirm frame meeting the correctness criteria of 14.3.7 has been received from peerMAC for the mesh peering instance identified by localLinkID and peerLinkID.
- CNF_RJCT—PeeringConfirm_Reject(peerMAC, localLinkID, peerLinkID, reasonCode) event indicates that a Mesh Peering Confirm frame from peerMAC for the mesh peering instance identified by localLinkID and peerLinkID is rejected due to incomplete or erroneous configuration, and reasonCode is the specific reason for rejection of the Confirm frame. See 14.3.7.2.
- CLS_ACPT—PeeringClose_Accept(peerMAC, localLinkID, peerLinkID, reasonCode) event indicates that a Mesh Peering Close frame meeting the correctness criteria of 14.3.8 has been received from peerMAC for the mesh peering instance identified by localLinkID and peerLinkID. The reasonCode specifies the reason that caused the generation of the Mesh Peering Close frame. See 14.3.8.2.

- REQ_RJCT—PeeringRequest_Reject(peerMAC, peerLinkID, reasonCode) event indicates a special incidence that the mesh STA rejects the incoming Mesh Peering Open frame requesting to set up a new mesh peering for some specified reason. The incoming request is identified by the peerMAC, peerLinkID is the peerLinkID received from the Mesh Peering Open frame, and reasonCode is the specific reason for rejection of the Mesh Peering Open frame. See 14.3.6.2.

The finite state machine may take an action triggered by an event. It uses two types of actions: sending a mesh peering Management frame and handling a timer.

Actions related to sending a mesh peering Management frame are as follows:

- sndOPN—sendOpen(peerMAC, localLinkID, meshConfiguration) is the action that the mesh STA takes to send its localLinkID and mesh STA Configuration in a Mesh Peering Open frame to the candidate peer mesh STA, whose MAC address is peerMAC. The MLME-MESHPEERINGMANAGEMENT.request primitive shall be invoked to send the frame to the peer mesh entity.
- sndCNF—sendConfirm(peerMAC, localLinkID, peerLinkID, meshConfiguration) is the action that the mesh STA takes to send its localLinkID and meshConfiguration in a Mesh Peering Confirm frame to the candidate peer mesh STA, whose MAC address is peerMAC. peerLinkID is the peerLinkID received from the Mesh Peering Open frame. The MLME-MESHPEERINGMANAGEMENT.request primitive shall be invoked to send the frame to the peer mesh entity.
- sndCLS—sendClose(peerMAC, localLinkID, peerLinkID, reasonCode) is the action that the mesh STA takes to send its localLinkID in a Mesh Peering Close frame to the peer mesh STA or candidate peer mesh STA, whose MAC address is peerMAC. peerLinkID is the peerLinkID received from the Mesh Peering Open frame, and reasonCode is the specific reason for closing the mesh peering. The MLME-MESHPEERINGMANAGEMENT.request primitive shall be invoked to send the frame to the peer mesh entity.

14.4.4 Timers

The following three timers are used by the finite state machine:

- a) The retryTimer triggers a resend of the Mesh Peering Open frame when a Mesh Peering Confirm frame was not received as a response. The retryTimer is set to the dot11MeshRetryTimeout.
- b) The confirmTimer signals that a link establishment attempt should be aborted because a Mesh Peering Confirm frame responding to a Mesh Peering Open frame was never received. The confirmTimer is set to dot11MeshConfirmTimeout.
- c) The holdingTimer signals that its mesh peering instance may be completely closed and facilitates graceful shutdown. The holdingTimer is set to dot11MeshHoldingTimeout.

The events associated with internal timers are represented in the state machine table as acronyms that indicate timer expiration. With each timer event there is an associated action.

- TOR1—This event indicates that the retryTimer has expired and dot11MeshMaxRetries has not been reached. The Mesh Peering Open frame shall be resent, an action represented in the state machine table by setR.
- TOR2—This event indicates that the retryTimer has expired and dot11MeshMaxRetries has been reached. The mesh peering instance shall be closed when TOR2 occurs.
- TOC—This event indicates that the confirmTimer has expired. When TOC event occurs, the mesh peering instance shall be closed, an action represented in the state machine table as setC.
- TOH—This event indicates that the holdingTimer has expired. When TOH occurs, the mesh peering instance shall be closed and the finite state machine shall transition to IDLE state, an action represented in the state machine table as setH.

14.4.5 State transitions

Table 14-2 and Figure 14-2 summarize the state transitions for the MPM protocol.

In Table 14-2, each row represents state transitions from the state to all other states. A blank entry indicates an impossible transition.

Table 14-2—MPM finite state machine

| | | To State | | | | | |
|------------|-----------|-------------------------|-------------------------|------------------------|---|--------------------------|---|
| | | IDLE | OPN_SNT | CNF_RCVD | OPN_RCVD | ESTAB | HOLDING |
| From State | IDLE | REQ_RJCT / sndCLS | ACTOPN / (sndOPN, setR) | | OPN_ACPT / (sndOPN, sndCNF, setR) | | |
| | OPN_SNT | | TOR1 / (sndOPN, setR) | CNF_ACPT / (clR, setC) | OPN_ACPT / (sndCNF) | | CLS_ACPT, OPN_RJCT, CNF_RJCT, TOR2, CNCL / (sndCLS, clR, setH) |
| | CNF_RCV_D | | | | | OPN_ACPT / (clC, sndCNF) | CLS_ACPT, OPN_RJCT, CNF_RJCT, CNCL / (sndCLS, clC, setH) TOC / (sndCLS, setH) |
| | OPN_RCV_D | | | | OPN_ACPT / sndCNF TOR1 / (sndOPN, setR) | CNF_ACPT / clR | CLS_ACPT, OPN_RJCT, CNF_RJCT, TOR2, CNCL / (sndCLS, clR, setH) |
| | ESTAB | | | | | OPN_ACPT / sndCNF | CLS_ACPT, OPN_RJCT, CNF_RJCT, CNCL / (sndCLS, setH) |
| | HOLDING | TOH / —, CLS_ACPT / clH | | | | | OPN_ACPT, CNF_ACPT, OPN_RJCT, CNF_RJCT / sndCLS |

In Figure 14-2, each arrow represents a state transition.

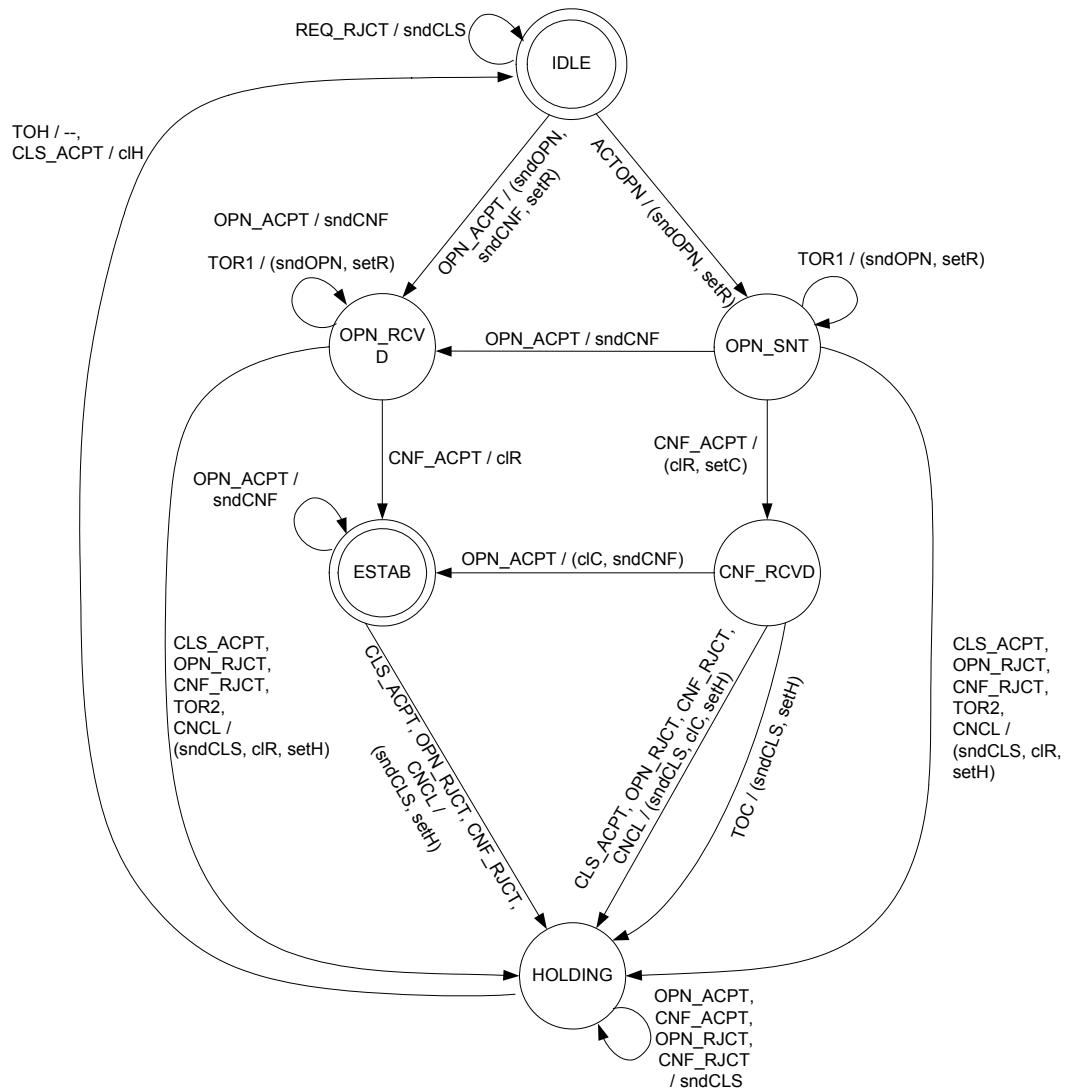

Figure 14-2—Finite state machine of the MPM protocol

The event/action representation is defined as the following. “E/A” string represents that the action A is taken given that the event E occurs. “E1, E2/A” string represents that the action A is taken given that the event E1 or event E2 occurs. “E/(A1, A2)” string represents that the action A1 and A2 are taken at a time when event E occurs.

Note that Table 14-2 and Figure 14-2 are used for illustration purposes. The protocol behavior is in the following subclauses.

14.4.6 IDLE state

IDLE is a quiescent state the finite state machine enters prior to establishing a new mesh peering.

When ACTOPN event occurs, the mesh STA shall set the retryCounter to 0, and perform a sndOPN action. The retryTimer shall be set and the finite state machine shall transition to OPEN_SNT state.

When an OPN_ACPT event occurs, the mesh STA shall perform a sndOPN action and sndCNF action, and set the retryTimer. The finite state machine shall transition to OPN_RCVD state.

When an REQ_RJCT event occurs, a Mesh Peering Close frame shall be sent to reject the mesh peering open request. The reason code in the Mesh Peering Close frame shall be set to the reason code in REQ_RJCT event. The finite state machine shall stay in the IDLE state.

All other events are ignored in this state.

14.4.7 OPN_SNT state

In the OPN_SNT state, the mesh STA waits for a Mesh Peering Confirm frame. In this state, the retryTimer is set.

When a CNCL event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS using the reason code specified by the CNCL event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CLS_ACPT event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS using the reason code specified by the CLS_ACPT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When an OPN_ACPT event occurs, the mesh STA shall send perform a sndCNF action. The finite state machine shall transition to OPN_RCVD state.

NOTE—The retryTimer is still in effect after the state transition.

When an OPN_RJCT event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS using the reason code specified by the OPN_RJCT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CNF_ACPT event occurs, the mesh STA shall clear the retryTimer and shall set the confirmTimer and the finite state machine shall transition to CNF_RCVD state.

When a CNF_RJCT event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS action using the reason code specified by the CNF_RJCT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a TOR1 event occurs, the Mesh STA shall perform a sndOPN action and the retryCounter shall be incremented. The retryTimer shall be and the finite state machine shall stay in the OPN_SNT state.

When a TOR2 event occurs, the mesh STA shall perform a sndCLS action using the reason code MESH-MAX-RETRIES. The holdingTimer shall be set, and the finite state machine shall transition to HOLDING state.

All other events shall be ignored in this state.

14.4.8 CNF_RCVD state

In the CNF_RCVD state, the mesh STA has received a Mesh Peering Confirm frame and is waiting for a Mesh Peering Open frame.

When a CNCL event occurs, the mesh STA shall clear the confirmTimer, perform a sndCLS action using the reason code MESH-PEERING-CANCELED, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CLS_ACPT event occurs, the mesh STA shall clear the confirmTimer, perform a sndCLS using the reason code MESH-CLOSE-RCVD, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When an OPN_ACPT event occurs, the mesh STA shall clear the confirmTimer and shall perform a sndCNF action. The finite state machine shall transition to ESTAB state.

When an OPN_RJCT event occurs, the mesh STA shall clear the confirmTimer, perform a sndCLS action using the reason code as specified by the OPN_RJCT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CNF_RJCT event occurs, the mesh STA shall clear the confirmTimer, perform a sndCLS action using the reason code as specified by the CNF_RJCT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When TOC event occurs, the mesh STA shall perform a sndCLS action using the reason code MESH-CONFIRM-TIMEOUT and set the holdingTimer. The finite state machine shall transition to HOLDING state.

All other events shall be ignored in this state.

14.4.9 OPN_RCVD state

In the OPN_RCVD state, the mesh STA has received a Mesh Peering Open frame and sent a Mesh Peering Open frame and the corresponding Mesh Peering Confirm frame. An incoming Mesh Peering Confirm is expected.

When a CNCL event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS action using the reason code MESH-PEERING-CANCELED, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CLS_ACPT event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS action, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When an OPN_ACPT event occurs, the mesh STA shall perform a sndCNF action. The finite state machine shall stay in the OPN_RCVD state.

When an OPN_RJCT event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS action using the reason code as specified by the OPN_RJCT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CNF_ACPT event occurs, the retryTimer shall be cleared. The finite state machine shall transition to ESTAB state.

When a CNF_RJCT event occurs, the mesh STA shall clear the retryTimer, perform a sndCLS action using the reason code as specified by the CNF_RJCT event, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a TOR1 event occurs, the Mesh STA shall perform a sndOPN action, increment the retryCounter, and set the retryTimer. The finite state machine shall stay in the OPN_RCVD state.

When a TOR2 event occurs, the mesh STA shall perform a sndCLS action using the reason code MESH-MAX-RETRIES. The holdingTimer shall be set, and the finite state machine shall transition to HOLDING state.

All other events shall be ignored in this state.

14.4.10 ESTAB state

In the ESTAB state, mesh peering has been successfully established with the peer mesh STA.

When a CNCL event occurs, the mesh STA shall perform a sndCLS action using the reason code MESH-PEERING-CANCELED, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When a CLS_ACPT event occurs, the mesh STA shall perform a sndCLS action using the reason code MESH-CLOSE-RCVD, and set the holdingTimer. The finite state machine shall transition to HOLDING state.

When an OPN_ACPT event occurs, the mesh STA shall respond by performing a sndCNF action. The finite state machine shall stay in the ESTAB state.

All other events shall be ignored in this state.

14.4.11 HOLDING state

In HOLDING state, the mesh STA is closing the mesh peering. The holdingTimer has been set according to the value of dot11Mesh HoldingTimeout.

When a CLS_ACPT event occurs, the holdingTimer shall be cleared. The finite state machine shall transition to IDLE state.

When any of the following four events occurs—OPN_ACPT, CNF_ACPT, OPN_RJCT, CNF_RJCT—the mesh STA shall send a Mesh Peering Close frame. The finite state machine shall stay in the HOLDING state.

When a TOH event occurs, the finite state machine shall transition to IDLE state.

All other events are ignored in this state.

14.5 Authenticated mesh peering exchange (AMPE)

14.5.1 Overview

The authenticated mesh peering exchange (AMPE) establishes an authenticated mesh peering between the mesh STAs, under the assumption that mesh PMKSA has already been established before the initiation of the protocol. An authenticated mesh peering includes a mesh peering, corresponding mesh TKSA, and the two mesh STAs mesh GTKSA.

The AMPE is also used to establish an authenticated peering between two APs that support the AP PeerKey protocol (as defined in 12.11) under the assumption that a PMK and PMKID have already been established before the initiation of the AMPE exchange.

The AMPE uses mesh peering Management frames. Parameters are exchanged via the RSNE, the Authenticated Mesh Peering Exchange element, and the MIC element.

The major functions provided by AMPE are security capabilities selection, key confirmation, and key management.

- The security capabilities selection function (specified in 14.5.2) is performed by agreeing on the security parameters used for the protocol instance.
- Key confirmation using the shared PMK is performed by verifying that the protection on the mesh peering Management frame is correct.
- Key management (specified in 14.5.7) is performed by the derivation of the temporal key in the mesh TKSA and the exchange of each mesh STA's MGTK.

During the AMPE handshake, the mesh STAs generate nonces and transmit them via mesh peering Management frames. The mesh STA shall generate a random value for its localNonce, as specified in 12.7.5. The candidate peer mesh STA is expected to generate a random value for the peerNonce, which the mesh STA receives from the candidate peer mesh STA in Confirm and Close Action frames.

Mesh peering Management frames used in the AMPE are protected using the deterministic authenticated encryption mode of AES-SIV (IETF RFC 5297).

14.5.2 Security capabilities selection

14.5.2.1 Instance Pairwise Cipher Suite selection

Pairwise cipher suite selectors WEP-40, WEP-104, and TKIP shall not be used as the pairwise cipher suite when dot11MeshSecurityActivated, dot11ProtectedTXOPNegotiationActivated, or dot11ProtectedQLoadReportActivated is true.

If the pairwise cipher suite has not been selected, a STA shall attempt to reach the agreement on the pairwise cipher suite using the following procedure in four steps:

- a) The STA shall announce the list of pairwise cipher suites it supports using an ordered list in the RSNE in the Mesh Peering Open frame. The first value in the list is the STA's most preferred cipher suite, and the last value the least preferred.
- b) If the STA receives a Mesh Peering Open frame from the candidate peer STA, the STA shall make its decision on the selected pairwise cipher suite based on the intersection of its own ordered list and the received ordered list.
 - 1) If the intersection is empty, the pairwise cipher suite selection fails and the STA generates the failure reason code MESH-INVALID-SECURITY-CAPABILITY and then takes the corresponding actions specified in 14.5.6.
 - 2) If the intersection contains more than one value, the selected cipher suite shall be the entry in the intersection list most preferred by the STA that has the largest MAC address in the lexicographic ordering.
- c) If the STA receives a Mesh Peering Confirm frame from the candidate peer STA before receiving a Mesh Peering Open frame, the STA shall verify that it supports the pairwise cipher suite chosen by the candidate peer STA. Otherwise, the selection fails and the STA shall generate the failure reason code MESH-INVALID-SECURITY-CAPABILITY. Furthermore, upon receiving a Mesh Peering Open frame, the STA shall verify that the accepted selected pairwise cipher suite matches the pairwise cipher suite chosen in step b). If they do not match, the selection fails and the STA shall generate the failure reason code MESH-INVALID-SECURITY-CAPABILITY. Otherwise, the pairwise cipher suite selection succeeds, and the STA shall proceed to step d).

- d) If the STA is generating a Mesh Peering Confirm frame, it shall set the Selected Pairwise Cipher Suite to the selected pairwise cipher suite upon successful pairwise cipher suite selection.

14.5.2.2 Group cipher suite selection

Group cipher suite selectors WEP-40, WEP-104, and TKIP shall not be used as the group cipher suite when dot11MeshSecurityActivated is true.

The mesh STA shall not use a different group cipher suite than the one used by the peer mesh STA or candidate peer mesh STA in the same MBSS.

A mesh STA shall announce in a Mesh Peering Open frame the group cipher suite it uses for broadcast protection. When it receives a Mesh Peering Open frame from a candidate peer, it shall verify that it supports the candidate's announced group cipher suite. In addition, if the mesh STA receives a Mesh Peering Confirm frame, it shall verify that it supports the group cipher suite listed in that frame. If either selection fails, the mesh STA shall issue the appropriate reply frame with the MESH-INVALID-SECURITY-CAPABILITY reason code.

14.5.3 Construction and processing AES-SIV-protected mesh peering Management frames

AES-SIV performs deterministic authenticated encryption and takes additional data that is authenticated but not encrypted (AAD). When encrypting and authenticating, AES-SIV takes a key, plaintext data to protect, and multiple distinct components of AAD, to produce a synthetic initialization vector and a cipher text. When verifying encrypted and authenticated data AES-SIV takes a key, a synthetic initialization vector, cipher text data to decrypt and verify, and AAD, to produce either plaintext or the symbol “FAIL,” indicating failure to decrypt and verify. Note that the AAD used in the encryption process shall be identical to the AAD used in the decryption process and the synthetic initialization vector produced by the encryption process shall be used in the decryption process.

When the mesh STA constructs a mesh peering Management frame, it shall follow the following procedure:

- The input key shall be the AEK
- The input plaintext shall be the Authenticated Mesh Peering element (see 9.6.16.2, 9.6.16.3, 9.6.16.4)
- The input AAD shall be three distinct components consisting of
 - 1) The localMAC
 - 2) The peerMAC
 - 3) The contents of the mesh peering Management frame from the category (inclusive) to the MIC element (exclusive)
- The output synthetic initialization vector shall be copied into the MIC field of the MIC element in the mesh peering Management frame
- The output cipher text shall become the remainder of the mesh peering Management frame after the MIC element

When the mesh STA verifies a mesh peering Management frame, it shall follow the following procedure:

- The input key shall be the AEK
- The input synthetic initialization vector shall be the MIC field of the MIC element in the mesh peering Management frame
- The input cipher text shall be the part of the mesh peering Management frame following the MIC element
- The input AAD shall be three distinct components consisting of

- 1) The peerMAC
- 2) The localMAC
- 3) The contents of the mesh peering Management frame from the category (inclusive) to the MIC element (exclusive)
- If AES-SIV returns the symbol “FAIL” processing of the frame shall be deemed a failure with a behavior dependent on the type of mesh peering Management frame
- If AES-SIV returns plaintext it shall be treated as the components of the mesh peering Management frame and processed accordingly

14.5.4 Distribution of group transient keys in an MBSS

The MGTK shall be a random or pseudorandom number. The mesh STA shall distribute the MGTK to the peer mesh STA using the Mesh Peering Open frame during the AMPE. Upon successful completion of AMPE, each mesh STA shall establish states for the peer mesh STA’s mesh GTKSA. The GTKData subfield in the Authenticated Mesh Peering Exchange element shall contain the MGTK concatenated by the Key RSC and the GTKExpirationTime (as specified in 9.4.2.118).

When dot11RSNAProtectedManagementFramesActivated is true, a mesh STA shall distribute the IGTK to the peer mesh STA using the Mesh Peering Open frame during the AMPE. Upon successful completion of AMPE, each mesh STA shall establish an IGTKSA (see 12.6.1.1.9) with the mesh peer.

14.5.5 Mesh peering Management frames for AMPE

14.5.5.1 General

The AMPE is inclusive of the mesh peering management (MPM) protocol. mesh peering Management frames for AMPE have additional processing and construction requirements on top of those for mesh peering Management frames.

The mesh peering Management frames shall be generated with additional information using the RSNE and the Authenticated Mesh Peering Exchange element to support AMPE.

14.5.5.2 Mesh peering open for AMPE

14.5.5.2.1 Generating Mesh Peering Open frames for AMPE

In addition to contents for establishing a mesh peering as specified in 14.3.6.1, the Mesh Peering Open frame, when used for the AMPE, shall contain the following:

- In the Mesh Peering Management element, the Mesh Peering Protocol Identifier shall be set to 1 “authenticated mesh peering exchange protocol.”
- In the Mesh Peering Management element, the Chosen PMK field shall be set to PMKID that identifies the mesh PMKSA the mesh STA established with the candidate peer mesh STA.
- The RSNE shall be identical to the RSNE in the STA’s Beacon and Probe Response frames.
- In the Authenticated Mesh Peering Exchange element:
 - The Selected Pairwise Cipher Suite field shall be set to the first cipher suite selector in the Pairwise Cipher Suite List field in RSNE.
 - The LocalNonce field shall be set to the localNonce value generated by the mesh STA for identifying the current mesh peering instance.
 - The PeerNonce field shall be set to 0.
 - If dot11MeshSecurityActivated is true, the GTKdata field shall be present and shall contain the data for the mesh STA’s MGTK. The GTKdata field shall not be present when AMPE is being

used as part of the AP PeerKey protocol (12.11.2). The components of the GTKdata field are specified in 14.5.4.

The Mesh Peering Open frame shall be protected using AES-SIV as specified in 14.5.3.

14.5.5.2.2 Processing Mesh Peering Open frames for AMPE

On receiving a Mesh Peering Open frame, the mesh STA shall verify the received frame. If AES-SIV returns the symbol “FAIL” the OPN_RJCT event shall be invoked to the corresponding AMPE finite state machine and the reason code “MESH-INVALID-GTK” is generated. Otherwise, processing continues.

The received frame shall be rejected if the security capability selection fails (see 14.5.2). The OPN_RJCT event shall be invoked to the corresponding AMPE finite state machine.

The peer mesh STA’s MGTK extracted from the Mesh Peering Open frame shall be added to the Receive MGTK SA in which the peer’s MAC address equals the MGTK Source mesh STA MAC address.

If all operations succeed, the mesh STA shall proceed to process the Mesh Peering Open frame on basic parameters as specified in 14.3.6.2.

14.5.5.3 Mesh peering confirm for AMPE

14.5.5.3.1 Generating Mesh Peering Confirm frames for AMPE

In addition to contents for establishing a mesh peering as specified in 14.3.7.1, the Mesh Peering Confirm frame, when used with the AMPE, shall contain the following:

- In the Mesh Peering Management element, the Mesh Peering Protocol Identifier shall be set to 1 “authenticated mesh peering exchange protocol.”
- The RSNE shall be the same as sent in the Mesh Peering Open frame.
- In the Authenticated Mesh Peering Exchange element:
 - The Selected Pairwise Cipher Suite field shall be set to the cipher suite selector that indicates the successfully selected pairwise cipher suite (specified in 14.5.2.1).
 - The PeerNonce field shall be set to the nonce value chosen by the peer mesh STA as received in the LocalNonce field in the Mesh Peering Open frame from the candidate peer mesh STA.
 - The GTKdata field shall not be present.
 - The IGTKdata field shall not be present.
 - The rest of fields are set to the same values sent in the Mesh Peering Open frame.

The Mesh Peering Confirm frame shall be protected using AES-SIV as specified in 14.5.3.

14.5.5.3.2 Processing Mesh Peering Confirm frames for AMPE

On receiving a Mesh Peering Confirm frame, the mesh STA shall verify the received frame. The received frame shall be discarded if AES-SIV returns the symbol “FAIL.”

If AES-SIV returns plaintext, the following operations shall be performed in order:

- a) The Selected Pairwise Cipher Suite is checked. If the security capability selection has been done and the received value from Chosen Pairwise Cipher Suite field is not the same as the agreed pairwise cipher suite, the STA shall reject the received frame and the CNF_RJCT event is invoked to the corresponding AMPE finite state machine with the failure reason code MESH-INVALID-SECURITY-CAPABILITY.

- b) If dot11MeshSecurityActivated is true the group cipher suite is checked. If the received group cipher suite is not supported by the mesh STA, the mesh STA shall reject the received Mesh Peering Confirm frame and the CNF_RJCT event is invoked to the corresponding AMPE finite state machine with the failure reason code MESH-INVALID-SECURITY-CAPABILITY.

If none of the cases is true, the mesh STA shall proceed to process the Mesh Peering Confirm Action frame on basic parameters as specified in 14.3.7.2.

14.5.5.4 Mesh peering close for AMPE

14.5.5.4.1 Generating Mesh Peering Close frames for AMPE

In addition to contents for closing a mesh peering as specified in 14.3.8.1, the Mesh Peering Close frame, when used for the AMPE, shall contain the following:

- In the Mesh Peering Management element, the Mesh Peering Protocol Identifier shall be set to 1 “authenticated mesh peering exchange protocol.”
- In the Mesh Peering Management element, the Chosen PMK field shall be set to the same value as sent in the Mesh Peering Open frame.
- In the Authenticated Mesh Peering Exchange element:
 - The Selected Pairwise Cipher Suite field shall be set to the same value as sent in the Mesh Peering Open frame.

NOTE—If the reason for sending the Mesh Peering Close is the pairwise cipher suite selection failure, the information in this field is used to inform the candidate peer mesh STA what was announced by the mesh STA for the mesh peering instance.

- The LocalNonce field shall be set to the same value as sent in the Mesh Peering Open frame.
- The PeerNonce field shall be set to the same value as received in the LocalNonce field of the Authenticated Mesh Peering Exchange element of the incoming mesh peering Management frame from the candidate peer mesh STA.

The Mesh Peering Close frame shall be protected using AES-SIV as specified in 14.5.3.

14.5.5.4.2 Processing Mesh Peering Close frames for AMPE

On receiving a Mesh Peering Close frame, the mesh STA shall verify the received frame. The received frame shall be discarded if AES-SIV returns the symbol “FAIL.”

If AES-SIV returns plaintext, the mesh STA shall proceed to process the Mesh Peering Close frame on basic parameters as specified in 14.3.8.2.

14.5.6 AMPE finite state machine

14.5.6.1 Overview

The finite state machine for AMPE supports all of the states, events, and actions defined for the finite state machine for the MPM protocol. In addition, new events, actions, and state transitions are added to specify the security functions for AMPE.

When a finite state machine is generated and activated for an AMPE instance, the localNonce shall be generated and used together with a new localLinkID to identify the instance.

14.5.6.2 Additional events and actions to MPM FSM

All events for rejecting or ignoring received Action frames shall report the corresponding reason code related to AMPE functions as described in 14.5.5.

In addition, there is one new event as follows:

- TOR3—This event indicates that the retryTimer has expired, the dot11MeshMaxRetries has been reached, the AMPE is enabled, but the mesh STA failed to confirm the selection of the shared mesh PMKSA. When this event triggers, the protocol instance shall be closed, but no Mesh Peering Close frame shall be sent.

The actions of sending mesh peering Management frames are updated as the following:

- sndOPN—Generate a Mesh Peering Open frame for the current AMPE protocol instance (as specified in 14.5.5.2.1) and send it to the candidate peer mesh STA.
- sndCNF—Generate a Mesh Peering Confirm frame for the current AMPE protocol instance (as specified in 14.5.5.3.1) and send it to the candidate peer mesh STA.
- sndClose—Generate a Mesh Peering Close frame for the current AMPE protocol instance (as specified in 14.5.5.4.1) and send it to the candidate peer mesh STA.

14.5.6.3 State transitions

All state transitions specified in MPM FSM shall be used for AMPE finite state machine.

In OPN_SNT state, the following are additional state transitions and actions:

When TOR3 event occurs, the retryTimer shall be cleared and the holdingTimer shall be set. The finite state machine shall transition to HOLDING state.

In OPN_RCVD state, the following are the additional actions:

When CNF_ACPT event occurs, in addition to the actions for MPM protocol, the mesh STA shall signal the completion of key management by utilizing the MLME-SETKEYS.request primitive to configure the agreed-upon mesh temporal pairwise key into the IEEE 802.11 MAC and by calling the MLME-SETPROTECTION.request primitive to enable its use.

In CNF_RCVD state, the following are the additional actions:

When OPN_ACPT event occurs, in addition to the actions for MPM protocol, the mesh STA shall signal the completion of key management by utilizing the MLME-SETKEYS.request primitive to configure the agreed-upon mesh temporal pairwise key into the IEEE 802.11 MAC and received MGTK and by calling the MLME-SETPROTECTION.request primitive to enable the usage.

Table 14-3 and Figure 14-3 specify the state transitions of the finite state machine for AMPE.

Table 14-3—AMPE finite state machine

| | | To State | | | | | |
|------------|-----------|-------------------------------|-------------------------------|---------------------------|---|-----------------------------|--|
| | | IDLE | OPN_SNT | CNF_RCVD | OPN_RCVD | ESTAB | HOLDING |

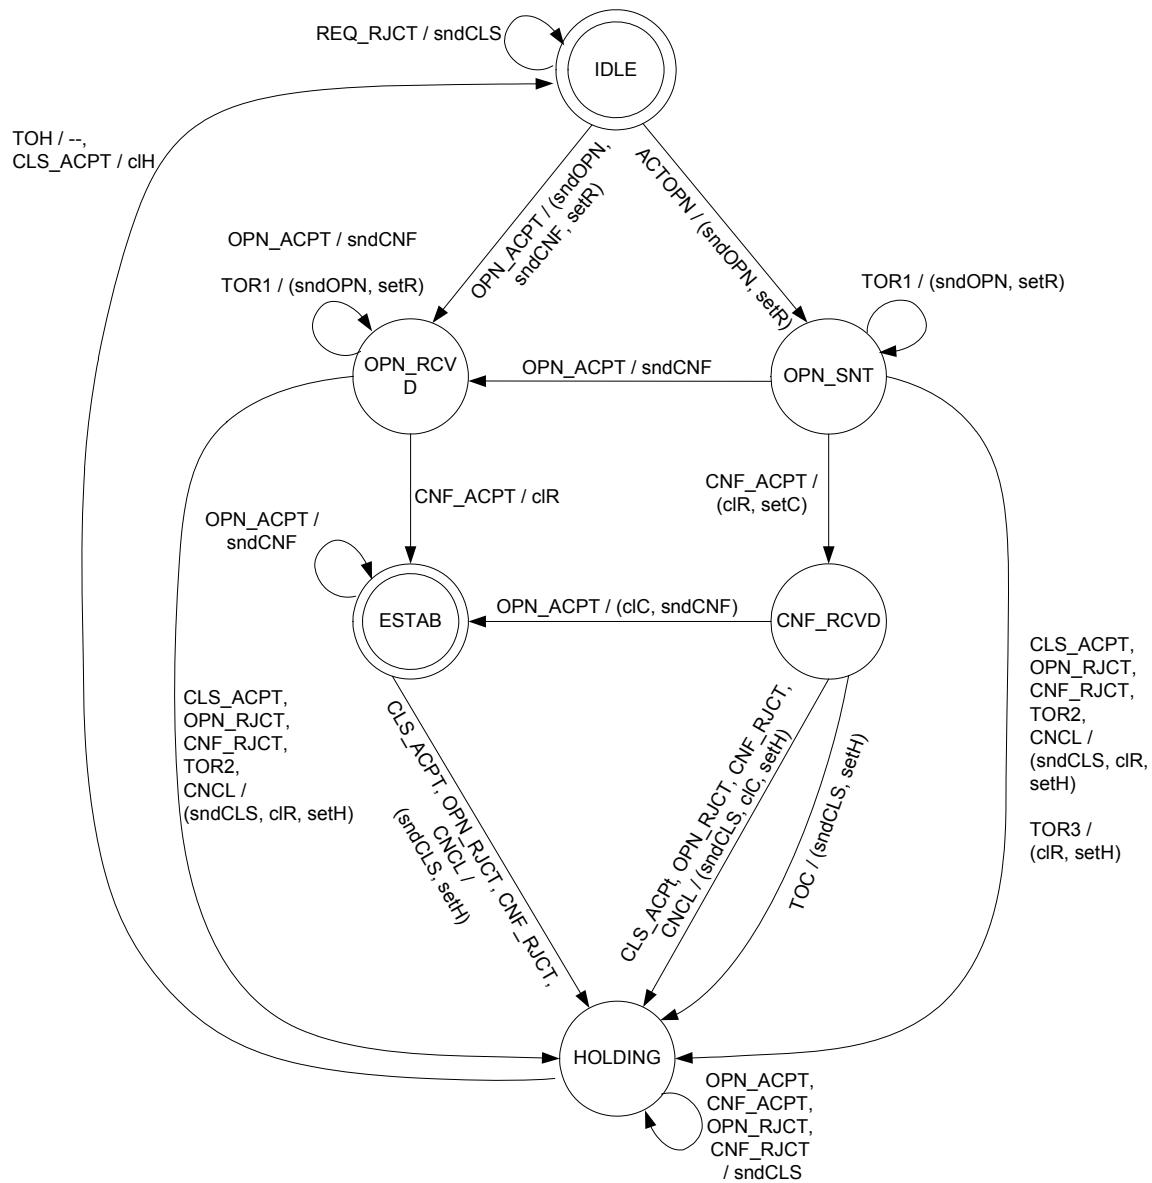

Figure 14-3—Finite state machine of the AMPE protocol

14.5.7 Keys and key derivation algorithm for the authenticated mesh peering exchange (AMPE)

To execute the AMPE and mesh group key handshake with a candidate peer STA, the local STA shall derive an authenticated encryption key (AEK) and a mesh temporal key (MTK) using the PMK it shares with the candidate peer STA.

The AEK is derived statically from the shared PMK. The MTK is derived from the shared PMK and dynamic information provided by the STA and candidate peer STA.

The AEK is mutually derived by the local STA and the peer STA once a new PMK has been selected. The AEK shall be derived from the PMK by

$\text{AEK} \leftarrow \text{KDF-Hash-256}(\text{PMK}, \text{"AEK Derivation"}, \text{Selected AKM Suite} \parallel \min(\text{localMAC}, \text{peerMAC}) \parallel \max(\text{localMAC}, \text{peerMAC}))$

where

KDF-Hash-256 is the key derivation function defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133)

Selected AKM Suite is a four octet string formed by concatenating the OUI or CID and suite type

The temporal key (MTK) shall be derived from the PMK by

$\text{MTK} \leftarrow \text{KDF-Hash-Length}(\text{PMK}, \text{"Temporal Key Derivation"}, \min(\text{localNonce}, \text{peerNonce}) \parallel \max(\text{localNonce}, \text{peerNonce}) \parallel \min(\text{localLinkID}, \text{peerLinkID}) \parallel \max(\text{localLinkID}, \text{peerLinkID}) \parallel \text{Selected AKM Suite} \parallel \min(\text{localMAC}, \text{peerMAC}) \parallel \max(\text{localMAC}, \text{peerMAC}))$

where

KDF-Hash-Length is the key derivation function defined in 12.7.1.7.2 using the hash algorithm identified by the AKM suite selector (see Table 9-133)

Length is cipher-suite dependent and is defined by the TK_bits value in Table 12-4.

Selected AKM Suite is a four octet string formed by concatenating the OUI or CID and suite type

“min” and “max” operations for IEEE 802 addresses are with the address converted to a positive integer, treating the first transmitted octet as the most significant octet of the integer as specified in 12.7.1.3

“min” and “max” operations for nonces are encoded as specified in 9.2.2

“min” and “max” operations for LinkIDs select the minimum and maximum, respectively, of the two unsigned integers. In the KDF context, LinkIDs are encoded as 16-bit unsigned integers, represented using the bit ordering conventions of 9.2.2.

The MTK is used to protect communications between two peer STAs. The local STA and peer STA derive an MTK per peering instance and may rekey the MTK using AMPE.

14.6 Mesh group key handshake

14.6.1 General

The mesh group key handshake may be used by either mesh STA, after a secure mesh peering has been established, to update the MGTK that it uses to protect group addressed MPDUs that it transmits to its peer mesh STAs.

The mesh STA may update its MGTK when a mesh peering is terminated.

To update the MGTK, the mesh STA shall execute the mesh group key handshake with each of its current peer mesh STAs. The “MGTK source” is the mesh STA that is sending the MGTK to a peer mesh STA using this protocol. A “MGTK recipient” is a mesh STA receiving the MGTK being sent by the MGTK Source.

The mesh group key handshake shall include the following two messages:

- Message 1: Mesh Group Key Inform frame
- Message 2: Mesh Group Key Acknowledge frame

Mesh Group Key Inform frame and Mesh Group Key Acknowledge frame are conventionally referred to as *mesh group key handshake frames*.

The mesh STA shall do an AMPE handshake before a mesh group key handshake if both are required to be done.

NOTE—It is impossible that the MGTK source initiates the mesh group key handshake before the AMPE completes successfully.

14.6.2 Protection on mesh group key handshake frames

Mesh group key handshake frames used in mesh group key handshake are protected using the deterministic authenticated encryption mode of AES-SIV (IETF-RFC 5297) when dot11MeshSecurityActivated is true.

When constructing protection on mesh group handshake frames, the following procedure shall be used:

- The key shall be the AEK from the current active security association with the peer mesh STA that receives the mesh group key handshake frame.
- The input plaintext shall be the AMPE Authenticated Mesh Peering element (see 9.6.16.5 and 9.6.16.6).
- The plaintext shall be the Authenticated Mesh Peering Exchange element.
- AAD shall be three distinct components as follows:
 - 1) The localMAC
 - 2) The peerMAC
 - 3) The contents of the mesh group key handshake frame from the category (inclusive) to the MIC element (exclusive)
- The synthetic initialization vector produced by AES-SIV shall be copied into the MIC field of the MIC element in the frame.
- The produced cipher text shall become the remainder of the mesh group key handshake frame after the MIC element.

When verifying the protection on the mesh group handshake frames, the following procedure shall be used:

- The key shall be the AEK from the current active security association with the peer mesh STA that receives the mesh group key handshake frame.
- AAD shall be three distinct components as follows:
 - 1) The peerMAC
 - 2) The localMAC
 - 3) The contents of the mesh group key handshake frame from the category (inclusive) to the MIC element (exclusive)
- The synthetic initialization vector shall be the MIC field of the MIC element in the frame.
- The cipher text shall be the content after the MIC element in the frame.
- If AES-SIV validation function takes above input
 - If the function returns the special symbol “FAIL,” the frame shall be discarded.
 - If the plaintext is returned successfully, the produced plaintext shall be treated as the contents after the MIC element in the frame.

14.6.3 Mesh Group Key Inform frame construction and processing

Mesh Group Key Inform frame shall be constructed as follows:

- The Authenticated Mesh Peering Exchange element shall be set as the following:
 - The Selected Pairwise Cipher Suite field shall be set to four octets of zero.
 - The LocalNonce field shall be set to the same value as sent in the Mesh Peering Open frame that established the mesh peering instance.

- The PeerNonce field shall be set to the same value as received in the LocalNonce field of the Authenticated Mesh Peering Exchange element of the incoming Mesh Peering Open frame that established the peering instance.
- The KeyReplayCounter field shall be set to the mesh STA's local replay counter value, incremented by 1, for the mesh peering. After setting this field, the local replay counter shall also be incremented by 1.
- The GTKdata field shall be present and shall contain the data for the MGTK from MGTK source. The components of the GTKdata are specified in 14.5.4.
- If management frame protection is used, the IGTKdata field shall be present and shall contain the data for the IGTK from IGTK source. The components of the IGTKdata are specified in 9.4.2.118.
- The MIC element shall be set according to the protection mechanism in 14.6.2.

The construction of AES-SIV protection on Mesh Group Key Inform frame shall use the construction procedure as in 14.6.2.

The MGTK source sends the Mesh Group Key Inform frame to the MGTK recipient.

On reception of Mesh Group Key Inform frame, the MGTK recipient shall use the verification procedure in 14.6.2 to validate the AES-SIV construction.

- If the validation recovers the plaintext successfully, the MGTK recipient shall proceed with the following procedure:
 - Verify that values in the LocalNonce field and the PeerNonce field in the Authenticated Mesh Peering Exchange element are the same as in the current valid mesh TKSA that the MGTK recipient established with the sender of the Mesh Group Key Inform frame. If there is any mismatch, the received Mesh Group Key Inform frame shall be discarded and no further action shall be taken.
 - Verify that the KeyReplayCounter has not yet been seen before, i.e., its value is strictly larger than that in any other mesh Group Key Inform frame received thus far during this security association. If this verification fails, the received Mesh Group Key Inform frame shall be discarded and no further action shall be taken.
 - Use the MLME-SETKEYS.request primitive to configure the temporal MGTK into its IEEE 802.11 MAC.
 - Respond by constructing and sending mesh group key handshake acknowledge to the MGTK source and incrementing the replay counter.

NOTE—The MGTK source increments and uses a new Key Replay Counter field value on every Mesh Group Key Inform frame, even retries, because the Mesh Group Key Acknowledge frame responding to an earlier Mesh Group Key Inform frame might have been lost. If the MGTK source did not increment the replay counter, the MGTK receiver discards the retry, and no responding Mesh Group Key Acknowledge frame will ever arrive.

- If the AES-SIV validation returns a special symbol “FAIL,” the Mesh Group Key Inform frame shall be discarded. No further action shall be taken.

14.6.4 Mesh Group Key Acknowledge frame construction and processing

Mesh Group Key Acknowledge frame shall be constructed as follows:

- The Authenticated Mesh Peering Exchange element shall be set as follows:
 - The Selected Pairwise Cipher Suite field shall be set to four octets of zero.
 - The LocalNonce field shall be set to the same value as sent in the Mesh Peering Open frame that established the mesh peering instance.

- The PeerNonce field shall be set to the same value as received in the LocalNonce field of the Authenticated Mesh Peering Exchange element of the incoming Mesh Peering Open frame that established the peering instance.
- The KeyReplayCounter shall be set to the same value as received in the Mesh Group Key Inform frame.
- The GTKdata field shall not be present.
- The IGTKdata field shall not be present.
- The MIC element shall be set according to the protection mechanism in 14.6.2.

The construction of AES-SIV protection on Mesh Group Key Acknowledge frame shall use the construction procedure as in 14.6.2.

The MGTK recipient sends the Mesh Group Key Acknowledge frame to the MGTK source.

On reception of Mesh Group Key Acknowledge frame, the MGTK source shall use the verification procedure in 14.6.2 to validate the AES-SIV construction.

- If the validation recovers the plaintext successfully, the MGTK source shall set the content of the Authenticated Mesh Peering Exchange element using the recovered plaintext and proceed with the following procedure:
 - Verify that values in the LocalNonce field and the PeerNonce field in the Authenticated Mesh Peering Exchange element are the same as in the current valid mesh TKSA that the MGTK source established with the sender of the Mesh Group Key Acknowledge frame. If there is any mismatch, the received Mesh Group Key Acknowledge frame shall be discarded and no further action shall be taken.
 - Verify that the KeyReplayCounter value matches the one that it has used for the mesh group key handshake. If this verification fails, the received Mesh Group Key Acknowledge frame shall be discarded and the MGTK source may invoke a retry to send a new Mesh Group Key Inform frame with a new KeyReplayCounter value.
- If the validation returns a special symbol “FAIL,” the Mesh Group Key Acknowledge frame shall be discarded and the MGTK source may invoke a retry to send a new Mesh Group Key Inform frame with a new KeyReplayCounter value.

14.6.5 Mesh group key implementation considerations

If the MGTK source does not receive a Mesh Group Key Acknowledge frame to its Mesh Group Key Inform frames, it shall attempt dot11MeshConfigGroupUpdateCount additional transmissions of the Mesh Group Key Inform frame. The retransmit timeout value shall be 100 ms for the first timeout, half the listen interval for the second timeout, and the listen interval for subsequent timeouts. If there is no listen interval or the listen interval is zero, then 100 ms shall be used for all timeout values. If it still has not received a response after this, then the MGTK source shall tear down the mesh peering and mesh TKSA with this MGTK recipient, by generating a CNCL event for the peering instance, and pass the event to the mesh peering instance controller.

14.7 Mesh security

During the AMPE, the peers negotiate, and agree upon, a pairwise ciphersuite and a group cipher suite. They also establish a mesh TKSA and mesh GTKSA to be used with the pairwise cipher suite and group cipher suite, respectively.

When dot11MeshSecurityActivated is true, all individually addressed mesh Data frames and individually addressed robust Management frames (see 12.2.8) shall be protected by the mesh TKSA, and all group

addressed Data frames and group addressed Action frames that are indicated as “Group Addressed Privacy” in Table 9-47 shall be protected by the mesh GTKSA.

When `dot11RSNAProtectedManagementFramesActivated` is true, group addressed robust Management frames that are not protected by the mesh GTKSA shall be protected using BIP (see 11.13).

14.8 Mesh path selection and metric framework

14.8.1 General

The term *mesh path selection* is used to describe selection of multi-hop paths between mesh STAs at the link layer. Mesh path selection creates forwarding information that is utilized for MSDU/MMPDU forwarding as described in 10.35.

14.8.2 Extensible path selection framework

This standard allows for alternative and flexible implementations of path selection protocols and metrics.

A mesh STA may include multiple protocol implementations (that is, the default protocol, vendor-specific protocols, etc.) as well as multiple metric implementations, but only one path selection protocol and only one path selection metric shall be used by a mesh STA at a time.

As described in 14.2.3 and 14.2.7, mesh STAs use the Mesh Configuration element (9.4.2.98) to announce the active path selection protocol and active path selection metric of the MBSS. This allows a neighbor mesh STA to identify if it should become a member of the MBSS and how it should establish mesh peerings with its members. This standard does not force an existing MBSS that is using a protocol other than the default protocol to switch to the default protocol when a new mesh STA requests mesh peering establishment. While it is possible, in principle, to implement such behavior, an algorithm to coordinate such reconfiguration is beyond the scope of this standard.

Path selection protocol and path selection metric are identified by a unique identifier as defined in 9.4.2.98.2 and 9.4.2.98.3, respectively. Also, each path selection protocol and each path selection metric specifies the following:

- Data type of metric values
- Length of the metric field
- Operator for aggregation of link metrics to a path metric; the symbol \oplus is used to identify an arbitrary operator for aggregation
- Comparison operator for determining a better or worse path; how this is performed depends on the actual comparison operator
- Initial value of the path metric (path selection metric only)

The standard defines a default path selection protocol (HWMP, 14.10) and a default path selection metric (airtime link metric, 14.9). Both shall be implemented on all mesh STAs.

14.8.3 Link metric reporting

A mesh STA may submit a link metric report to or request a link metric report from its neighbor peer mesh STA by transmitting a Mesh Link Metric Report frame. A mesh STA receiving a Mesh Link Metric Report element with the Request subfield of the Flags field equal to 1 shall reply with a Mesh Link Metric Report frame containing the link metric value for the corresponding link.

Upon reception of a Mesh Link Metric Report frame, the mesh STA may update its local link metric information using the link metric information received. The procedure to update the local link metric information with the link metric information received from a neighbor peer mesh STA is outside the scope of the standard.

14.9 Airtime link metric

This subclause defines a default link metric that may be used by a path selection protocol to identify an efficient radio-aware path. The extensibility framework allows this metric to be overridden by any path selection metric as specified in the mesh profile.

Airtime reflects the amount of channel resources consumed by transmitting the frame over a particular link. This measure is approximate and designed for ease of implementation and interoperability.

The airtime for each link is calculated as follows:

$$c_a = \left[O + \frac{B_t}{r} \right] \frac{1}{1 - e_f}$$

where

- O and B_t are constants listed in Table 14-4
- input parameter r is the data rate (in Mb/s)
- input parameter e_f is the frame error rate for the test frame size B_t
- rate r represents the data rate at which the mesh STA would transmit a frame of standard size B_t based on current conditions, and its estimation is dependent on local implementation of rate adaptation
- frame error rate e_f is the probability that when a frame of standard size B_t is transmitted at the current transmission bit rate r , the frame is corrupted due to transmission error; its estimation is a local implementation choice. Frame failures due to exceeding Mesh TTL should not be included in this estimate as they are not correlated with link performance.

The airtime link metric shall be encoded as an unsigned integer in units of 0.01 TU.

Table 14-4—Airtime cost constants

| Parameter | Recommended value | Description |
|-----------|-------------------------|---|
| O | Varies depending on PHY | Channel access overhead, which includes frame headers, training sequences, access protocol frames, etc. |
| B_t | 8192 | Number of bits in test frame |

Table 14-5 gives the parameters of the airtime link metric for the extensible path selection framework.

An example of the airtime link metric is shown in S.5.

Table 14-5—Parameters of the airtime link metric for extensible path selection framework

| Parameter | Notes |
|---------------------------------|---|
| Path Selection Metric ID | See Table 9-218 in 9.4.2.98.3 |
| Data type | Unsigned integer, $0 \leq \text{metric value} < 4\,294\,967\,296$ |
| Length of metric field | 4 octets |
| Operator for metric aggregation | addition (+) |
| Comparison operator | <i>less than, equal to, greater than</i> as used with integers — metric a is <i>better than</i> metric b iff $a < b$ — metric a is <i>equal to</i> metric b iff $a = b$ — metric a is <i>worse than</i> metric b iff $a > b$ |
| Initial value of path metric | 0 |

14.10 Hybrid wireless mesh protocol (HWMP)

14.10.1 General

The hybrid wireless mesh protocol (HWMP) is a mesh path selection protocol that combines the flexibility of on-demand path selection with proactive topology tree extensions. The combination of reactive and proactive elements of HWMP enables efficient path selection in a wide variety of mesh networks (with or without access to the infrastructure).

HWMP uses a common set of protocol elements, generation and processing rules inspired by Ad Hoc On-Demand Distance Vector (AODV) protocol (IETF RFC 3561 [B38]) adapted for MAC address-based path selection and link metric awareness. HWMP is completely specified herein and does not require reference to AODV specifications or descriptions.

HWMP supports two modes of operation depending on the configuration. These modes provide different levels of functionality as follows:

- On-demand mode: The functionality of this mode is always available, independent of whether a root mesh STA is configured in the MBSS or not. It allows mesh STAs to communicate using peer-to-peer paths.
- Proactive tree building mode: In this mode, additional proactive tree building functionality is added to the on-demand mode. This can be performed by configuring a mesh STA as root mesh STA using either the proactive PREQ mechanism or proactive RANN mechanism. The proactive PREQ mechanism creates paths from the mesh STAs to the root, using only group addressed communication. The RANN mechanism creates paths between the root and each mesh STA using acknowledged communication.

These modes are not exclusive. On-demand and proactive modes are used concurrently, because the proactive modes are extensions of the on-demand mode.

NOTE—One example of concurrent usage of on-demand and proactive mode is for two mesh STAs that are part of the same mesh BSS (or STAs that are proxied by mesh STAs in the same MBSS) to begin communicating using the proactively built tree but subsequently to perform an on-demand discovery for a direct path. This type of concurrent usage of the proactive and on-demand modes allows communication to begin immediately (by forwarding all traffic to the root, which knows all mesh STAs and addresses proxied by mesh STAs in the MBSS) while an on-demand discovery finds a shorter path between two mesh STAs (or STAs that are proxied by mesh STAs in the same MBSS).

All HWMP modes of operation utilize common processing rules and primitives. HWMP elements are the PREQ (path request) element, PREP (path reply) element, PERR (path error) element, and RANN (root announcement) element. The metric cost of the links determines which paths HWMP builds. In order to propagate the metric information between mesh STAs, a Metric field is used in the PREQ, PREP, and RANN elements.

Path selection in HWMP uses a sequence number mechanism to enable mesh STAs to distinguish current path information from stale path information at all times in order to maintain loop-free connectivity. Each mesh STA maintains its own HWMP SN, which is propagated to other mesh STAs in the HWMP elements. Rules for maintaining HWMP SNs are given in 14.10.8.3.

14.10.2 Terminology

This subclause describes terminology for HWMP, especially for the process of path discovery. Terms such as Path Originator or Path Target designate very specific entities within the path discovery process. They stay with the same assigned entity for the whole path discovery process and other procedures related to this path discovery. Figure 14-4 illustrates an example utilizing this terminology.

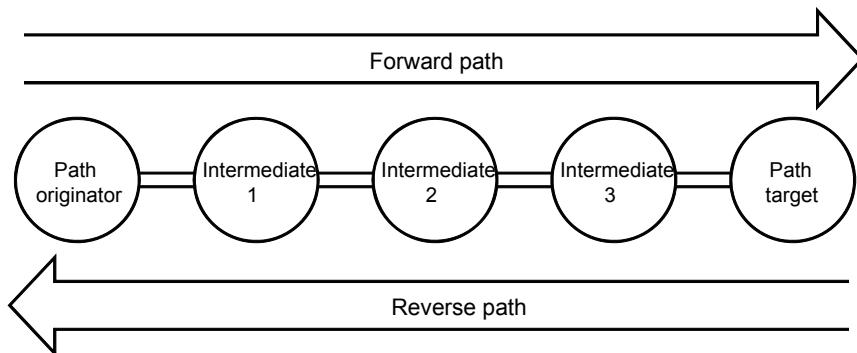

Figure 14-4—Illustration of definitions

NOTE—Both the path target and path originator are a path destination for the forward path and the reverse path respectively.

The following terms are used within the context of a single PREQ element / PREP element pair, a so-called HWMP path discovery:

- **path originator:** The path originator is the mesh STA that triggers the path discovery.
- **path originator address:** The MAC address of the path originator.
- **path target:** The path target is the entity to which the path originator attempts to establish a path.

NOTE—When an originator mesh STA initially attempts to establish a path to a target, it does not know whether the target is a mesh STA in the mesh BSS or not. Only when the Originator receives a PREP element does it learn if the target is a mesh STA in the mesh BSS or not. If the target is in the mesh BSS, it is referred to as a *target mesh STA*. If the target is outside the mesh BSS, the term target proxy mesh gate refers to the mesh gate proxying for the target.

- **path target address:** The MAC address of the path target.
- **intermediate mesh STA:** The intermediate mesh STA is the mesh STA that participates in path selection and is neither path originator nor path target.
- **intermediate mesh STA address:** The MAC address of the intermediate mesh STA.
- **forward path:** The forward path is the mesh path to the path target, set up at the path originator and intermediate mesh STAs.
- **reverse path:** The reverse path is the mesh path to the path originator, set up at the path target and intermediate mesh STAs.

- **HWMP sequence number (HWMP SN):** Each mesh HWMP path selection element contains an HWMP SN that allows recipients to distinguish newer from stale information. An HWMP SN is specific to a mesh STA. See also 14.10.8.3.
- **forwarding information:** The forwarding information maintained by an originator mesh STA, an intermediate mesh STA, or a target mesh STA that allows the mesh STA to perform its path selection and forwarding functions.
 The terminology used when discussing forwarding information is relative to the mesh STA (reference mesh STA, given mesh STA or local mesh STA) and a particular mesh destination of the path. The following terms are specific to a given instance of the forwarding information:
 - **destination mesh STA:** The end station (mesh STA) of a (forward or reverse) path.
 - **destination mesh STA address:** The MAC address of the destination mesh STA.
 - **destination HWMP SN:** The HWMP SN of the destination mesh STA.
 - **next-hop mesh STA:** The next-hop mesh STA is the next peer mesh STA on the mesh path to the destination mesh STA.
 - **next-hop mesh STA address:** The MAC address of the next-hop mesh STA.
 - **precursor mesh STA:** A precursor mesh STA is a neighbor peer mesh STA on the mesh path that identifies a given mesh STA as the next-hop mesh STA to the destination mesh STA.
 - **precursor mesh STA address:** The MAC address of the precursor mesh STA.
 - **lifetime:** The time during which forwarding information remains active (see 14.10.8.4)
- **unreachable destination:** A destination mesh STA is considered unreachable by a source mesh STA or an intermediate mesh STA if the link to the next hop of the mesh path to this destination mesh STA, as derived from its forwarding information, is no longer usable.
- **element time to live (Element TTL):** An integer number that is used to limit the number of hops an HWMP element may be processed and propagated. Note that this Element TTL is different from the Mesh TTL in the Mesh Control field (see 9.2.4.7.3).
- **root mesh STA:** A root mesh STA is configured to originate proactive PREQ elements or RANN elements. It is the root of a path selection tree.

Table 14-6 and Table 14-7 show the roles of the various mesh STAs in the forward path and reverse path generated as a result of the full PREQ element and PREP element processing as shown in Figure 14-4. Each row in the table contains the roles of a forward/reverse path from the reference mesh STA's perspective.

Table 14-6—Precursor and next hop examples (forward path)

| Forward path (to Path Target) | | | |
|-------------------------------|--------------------|-------------------|----------------------|
| Reference mesh STA | Precursor mesh STA | Next-hop mesh STA | Destination mesh STA |
| Path Originator | N/A | Intermediate 1 | Path Target |
| Intermediate 2 | Intermediate 1 | Intermediate 3 | Path Target |
| Path Target | Intermediate 3 | N/A | Path Target |

Table 14-7—Precursor and next hop examples (reverse path)

| Reverse path (to Path Originator) | | | |
|-----------------------------------|--------------------|-------------------|----------------------|
| Reference mesh STA | Precursor mesh STA | Next-hop mesh STA | Destination mesh STA |
| Path Originator | Intermediate 1 | N/A | Path Originator |
| Intermediate 2 | Intermediate 3 | Intermediate 1 | Path Originator |
| Path Target | N/A | Intermediate 3 | Path Originator |

14.10.3 On-demand path selection mode

If a source mesh STA needs to find a path to a destination mesh STA using the on-demand path selection mode, it broadcasts a PREQ element with the path target specified in the list of targets and the metric field initialized to the initial value of the active path selection metric.

When a mesh STA receives a new PREQ element, it creates or updates its path information to the originator mesh STA and propagates the PREQ element to its neighbor peer mesh STAs if the PREQ element contains a greater HWMP SN, or the HWMP SN is the same as the current path and the PREQ element offers a better metric than the current path. Each mesh STA may receive multiple copies of the same PREQ element that originated at the originator mesh STA, each PREQ element traversing a unique path.

Whenever a mesh STA propagates a PREQ element, the metric field in the PREQ element is updated to reflect the cumulative metric of the path to the originator mesh STA.

If the mesh STA that received a PREQ element is the target mesh STA, it sends a PREP element back to the originator mesh STA after creating or updating a path to the originator mesh STA.

The PREQ element provides the TO (Target Only) subfield that allows path selection to take advantage of existing paths to the target mesh STA by allowing an intermediate mesh STA to return a PREP element to the originator mesh STA. If the TO (Target Only) subfield is 1, only the target mesh STA responds with a PREP element. The effect of setting the TO (Target Only) subfield to 0 is the quick establishment of a path using the PREP element generated by an intermediate mesh STA, allowing the forwarding of MSDUs with a low path selection delay. In order to select (or validate) the best path during the path selection procedure, the intermediate mesh STA that responded with a PREP element propagates the PREQ element with the TO (Target Only) subfield set to 1. This prevents all other intermediate mesh STAs on the way to the target from sending a PREP element.

Intermediate mesh STAs create a path to the target mesh STA on receiving the PREP element, and also forward the PREP element toward the originator. When the originator receives the PREP element, it creates a path to the target mesh STA. If the target mesh STA receives further PREQ elements with a better metric, then the target updates its path to the originator with the new path and also sends a new PREP element to the originator along the updated path. A bidirectional, best metric end-to-end path is established between the originator and target mesh STA.

14.10.4 Proactive tree building mode

14.10.4.1 General

There are two mechanisms for proactively disseminating path selection information for reaching the root mesh STA. The first method uses a *proactive* PREQ element and is intended to create paths between all

mesh STAs and the root mesh STA in the network proactively. The second method uses a RANN element and is intended to distribute path information for reaching the root mesh STA but there is no forwarding information created.

A mesh STA configured as root mesh STA sends either proactive PREQ elements or proactive RANN elements periodically.

14.10.4.2 Proactive PREQ mechanism

The PREQ tree building process begins with a proactive PREQ element sent by the root mesh STA, with the Target Address set to all 1s and the TO subfield set to 1. The PREQ element contains the path metric (set to the initial value of the active path selection metric by the root mesh STA) and an HWMP SN. The proactive PREQ element is sent periodically by the root mesh STA, with increasing HWMP SNs.

A mesh STA receiving a proactive PREQ element creates or updates its forwarding information to the root mesh STA, updates the metric and hop count of the PREQ element, records the metric and hop count to the root mesh STA, and then transmits the updated PREQ element. Information about the presence of and distance to available root mesh STA(s) is disseminated to all mesh STAs in the network.

Each mesh STA may receive multiple copies of a proactive PREQ element, each traversing a unique path from the root mesh STA to the mesh STA. A mesh STA updates its current path to the root mesh STA if and only if the PREQ element contains a greater HWMP SN, or the HWMP SN is the same as the current path and the PREQ element offers a better metric than the current path to the root mesh STA. The processing of the proactive PREQ element is the same as the processing of the PREQ element in the on-demand mode described in 14.10.3.

If the proactive PREQ element is sent with the Proactive PREP subfield set to 0, the recipient mesh STA may send a proactive PREP element. A proactive PREP element is necessary, for example, if the mesh STA has data to send to the root mesh STA, thus requiring the establishment of a forward path from the root mesh STA. During the time the forward path is required, the recipient mesh STA shall send a proactive PREP element even if the Proactive PREP subfield is set to 0. Guidance on controlling the generation of proactive PREQ elements in such a case is given in S.6.

If the PREQ element is sent with a Proactive PREP subfield set to 1, the recipient mesh STA shall send a proactive PREP element. The proactive PREP element establishes the path from the root mesh STA to the mesh STA.

14.10.4.3 Proactive RANN mechanism

The root mesh STA periodically propagates a RANN element into the network. The information contained in the RANN element is used to disseminate path metrics to the root mesh STA, but reception of a RANN element does not establish a path.

Upon reception of a RANN element, each mesh STA that has to create or refresh a path to the root mesh STA sends an individually addressed frame containing a PREQ element to the root mesh STA via the mesh STA from which it received the RANN element.

The root mesh STA sends a PREP element in response to each PREQ element. The individually addressed frame containing a PREQ element creates the reverse path from the root mesh STA to the originator mesh STA, while the PREP element creates the forward path from the mesh STA to the root mesh STA.

14.10.5 Collocated STAs

HWMP terminology strictly refers to a STA whose address is used for destination mapping (i.e., the originator address, the intermediate mesh STA address, or the target address). HWMP terminology does not make any assumption about the address used for communication over the WM (i.e., the Transmitter Address and the Receiver Address). For example, there is no requirement that the Path Originator or the Path Target of an HWMP path are the same as the address used for transmitting the first and receiving the last (respectively) HWMP Mesh Path Selection frame containing a PREQ element.

The corollary to this is that the first hop of a PREQ element may have a transmitter address that is not the same as the Originator address in the PREQ element and that the first hop may have a transmitter address that is not the same as the source address. In order to determine whether a transmission is a first hop or not, mesh STAs should not compare the source and transmitter addresses. Instead, this determination can be made by looking at the hop count field of the PREQ element (which is not used as an acceptance criterion).

14.10.6 Parameters for extensible path selection framework

Table 14-8 gives the parameters of HWMP for the extensible path selection framework (see 14.8.2).

Table 14-8—Parameters of HWMP for extensible path selection framework

| Parameter | Notes |
|---------------------------------|--|
| Path Selection Protocol ID | See Table 9-217 in 9.4.2.98.2 |
| Data type of metric field | As defined by active path selection metric |
| Length of metric field | 4 octets |
| Operator for metric aggregation | As defined by active path selection metric |
| Comparison operator | As defined by active path selection metric |
| Initial value of path metric | As defined by active path selection metric |

14.10.7 Addressing of HWMP Mesh Path Selection frame

All HWMP elements are sent in an HWMP Mesh Path Selection frame (see 9.6.17.3). The RANN element may also be sent in a Beacon frame. “Cases” refer to the different conditions that trigger the transmission of an HWMP Mesh Path Selection frame. PREQ element cases are specified in 14.10.9.3. PREP element cases are specified in 14.10.10.3. PERR element cases are specified in 14.10.11.3. RANN element cases are specified in 14.10.12.3.

Note that the PREQ Addressing Mode subfield in the Flags field identifies the propagation mode of the PREQ element; an Addressing Mode subfield equal to 0 indicates that the PREQ element is group addressed, an Addressing Mode subfield equal to 1 indicates that the PREQ element is individually addressed.

The addresses of the HWMP Mesh Path Selection frame shall be as follows:

- PREQ element group addressed—Addressing Mode subfield = 0 [Case A: Path Discovery (Original transmission), Case B: Path Maintenance (Original transmission), Case C: Proactive PREQ element (Original transmission), and Case E: PREQ element Propagation]:
- Address 1: Group address
- Address 2: Address of the mesh STA sending the PREQ element
- Address 3: Same as Address 2

- PREQ element individually addressed—Addressing Mode subfield = 1 [Case D: Root Path Confirmation (Original transmission)]:
 - Address 1: Address 2 of the frame containing the RANN element that triggered the PREQ element
 - Address 2: Address of the mesh STA sending the PREQ element
 - Address 3: Same as Address 2
- PREQ element individually addressed—Addressing Mode subfield = 1 [Case E: PREQ element Propagation]:
 - Address 1: Next-hop MAC address to the mesh STA identified as the Target MAC address in the PREQ element
 - Address 2: Address of the mesh STA sending the PREQ element
 - Address 3: Same as Address 2
- PREP element Case A: Original transmission, Case C: Intermediate reply, Case D: Proactive PREP element in Proactive PREQ element mode:
 - Address 1: Address of the next hop to the Originator Mesh STA Address in the PREQ element that triggered the PREP element
 - Address 2: Address of the mesh STA sending the PREP element
 - Address 3: Same as Address 2
- PREP element Case B: PREP element Propagation:
 - Address 1: Address of the next hop to the Originator Mesh STA Address in the PREP element that triggered the PREP element
 - Address 2: Address of the mesh STA sending the PREP element
 - Address 3: Same as Address 2
- PERR element individually addressed [Case A: Original transmission—next hop is unusable]:
 - Address 1: Address of each one of the precursors for which the active forwarding information has been invalidated [see Case A, 14.10.11.3]
 - Address 2: Address of the mesh STA sending the PERR element
 - Address 3: Same as Address 2
- PERR element individually addressed [Case B: Original transmission—missing forwarding information]:
 - Address 1: Address of the transmitter of the frame that triggered the PERR element (see Case B, 14.10.11.3)
 - Address 2: Address of the mesh STA sending the PERR element
 - Address 3: Same as Address 2
- PERR element individually addressed [Case C: Original transmission (proxy information is unusable)]:
 - Address 1: Address of each one of the neighbor peer mesh STAs
 - Address 2: Address of the mesh STA sending the PERR element
 - Address 3: Same as Address 2
- PERR element individually addressed [Case D: PERR element propagation]:
 - Address 1: Address of each one of the precursors for which the active forwarding information has been invalidated (see 14.10.11.4.3)
 - Address 2: Address of the mesh STA sending the PERR element
 - Address 3: Same as Address 2
- PERR element group addressed [all cases]:
 - Address 1: Group address
 - Address 2: Address of the mesh STA sending the PERR element
 - Address 3: Same as Address 2

- RANN element all cases:
 - Address 1: Group address
 - Address 2: Address of the mesh STA sending the RANN element
 - Address 3: Same as Address 2

Multiple HWMP elements may be sent in the same HWMP Mesh Path Selection frame if they share the same intended Address 1.

14.10.8 General rules for processing HWMP elements

14.10.8.1 General

This subclause describes the rules for the processing of the following components of the HWMP elements:

- HWMP SN
- Element TTL
- Metric

14.10.8.2 HWMP propagation

The term *propagate* is used to describe the means by which elements are not transmitted “as is” across the network but are processed and modified along the way. Many HWMP elements are intended to be processed and propagated across an MBSS by mesh STAs. Each propagation is subject to certain rules or limitations as explained in the following subclauses. Certain parameters in the HWMP elements are updated during the propagation. See 14.10.9, 14.10.10, 14.10.11, and 14.10.12.

The originator of an HWMP element sets the initial value of the Element TTL. The mesh STA that receives the HWMP element shall propagate it if the received value of Element TTL is greater than 1. Before propagating the HWMP element, the mesh STA decrements the Element TTL value.

In general, the propagation of an HWMP element is not subject to a delay. Exception exists for the RANN element as described in 14.10.12.

14.10.8.3 HWMP sequence numbering

HWMP uses sequence numbers to prevent the creation of path loops and to distinguish stale and fresh path information. Each mesh STA keeps its own HWMP SN that it increments, uses in HWMP elements, and processes according to the HWMP rules. HWMP SNs for other mesh STAs are maintained in the forwarding information (see 14.10.8.4).

An HWMP SN is included in the PREQ, PREP, PERR, and RANN elements. The HWMP SN in the forwarding information is updated whenever a mesh STA receives new (i.e., not stale) information about the HWMP SN from a PREQ, PREP, or PERR element that may be received relative to that originator mesh STA, target mesh STA, or destination mesh STA.

HWMP depends on each mesh STA in the network to own and maintain its HWMP SN to guarantee the loop-freedom of all paths toward that mesh STA. A mesh STA increments its own HWMP SN in the following two circumstances:

- If it is an originator mesh STA, it shall increment its own HWMP SN immediately before it starts a path discovery. This prevents conflicts with previously established reverse paths toward the originator mesh STA. However, it might be advantageous not to increment the HWMP SN too frequently. An optional mechanism for achieving this is described in 14.10.8.6.

- If it is a target mesh STA, it shall update its own HWMP SN to maximum (current HWMP SN, target HWMP SN in the PREQ element) + 1 immediately before it generates a PREP element in response to a PREQ element. The target HWMP SN of the PREQ element is relevant when a link was broken along the path and the stored sequence number was increased at an intermediate mesh STA.

Comparing HWMP SNs is done using a circular modulo 2^{32} comparison.

In general, when a mesh STA receives an element with an HWMP SN that is less than the HWMP SN in the corresponding forwarding information, it discards the received element. If they are the same, the outcome (element processed or not) depends on the type of the element and some additional conditions. These cases are noted in the applicable element descriptions.

The only circumstance in which a mesh STA may change the HWMP SN of another mesh STA in the forwarding information independently of the reception of an HWMP element originated by this mesh STA is in response to a broken or no longer usable link to the next hop toward that destination mesh STA. The mesh STA determines which destinations use a particular next hop by consulting its forwarding information. In this case, for each destination that uses the next hop, the mesh STA increments the HWMP SN in the forwarding information and marks the path as invalid (see also 14.10.11). Whenever any forwarding information containing an HWMP SN greater than the recorded HWMP SN for an affected destination is received by a mesh STA that has marked that recorded forwarding information as invalid, the mesh STA shall update its forwarding information according to the information contained in the update.

14.10.8.4 Forwarding information

In addition to the parameters contained in the basic forwarding information as described in 10.35.2, the forwarding information to a destination defined by HWMP also contains at least the destination HWMP SN, the path metric, and the number of hops.

PREQ elements and PREP elements create or update the forwarding information of the mesh STAs that process these elements as follows:

- The mesh STA may create or update its forwarding information to the transmitter of the element if the path metric improves.
- The mesh STA shall create or update its forwarding information to the originator mesh STA, if it received a PREQ element, and one of the following conditions is met:
 - The Originator HWMP SN > HWMP SN in the forwarding information for this originator mesh STA, or
 - The Originator HWMP SN = HWMP SN in the forwarding information for this originator mesh STA AND the updated path metric is better than the path metric in the forwarding information.
- The mesh STA shall create or update its forwarding information to the target mesh STA, if it received a PREP element, and one of the following conditions is met:
 - The Target HWMP SN > HWMP SN in the forwarding information for this target mesh STA, or
 - The Target HWMP SN = HWMP SN in the forwarding information for this target mesh STA AND the updated path metric is better than the path metric in the forwarding information.

Table 14-9 defines the values to be stored in the different fields of the forwarding information after a PREQ element or PREP element has been received.

Changes to the forwarding information in other situations, for instance, when processing a PERR element (see 14.10.11), are described in the corresponding clauses.

Table 14-9—Data for creation and update of forwarding information due to PREQ element and PREP element

| Field of forwarding information | Received PREQ element | | Received PREP element | |
|---------------------------------|---|---|---|---|
| | Forwarding information for transmitter of PREQ element | Forwarding information for originator mesh STA | Forwarding information for transmitter of PREP element | Forwarding information for target mesh STA |
| HWMP SN | Invalid if created, no change if updated | PREQ element field Originator HWMP Sequence Number | Invalid if created, no change if updated | PREP element field Target HWMP Sequence Number |
| Next hop | Transmitter address of the Management frame containing the PREQ element | Transmitter address of the Management frame containing the PREQ element | Transmitter address of the Management frame containing the PREP element | Transmitter address of the Management frame containing the PREP element |
| Path metric | Accumulation of the initial value of the path metric with the metric of the link to the transmitter of the PREQ element | Accumulation of the value of PREQ element field Metric with the metric of the link to the transmitter of the PREQ element | Accumulation of the initial value of the path metric with the metric of the link to the transmitter of the PREP element | Accumulation of the value of PREP element field Metric with the metric of the link to the transmitter of the PREP element |
| Number of hops | 1 | Value of PREQ element field Hop Count + 1 | 1 | Value of PREP element field Hop Count + 1 |
| Precursor list | No change | No change except in case of an intermediate reply [see 14.10.9.4.3 step f)] | No change | See 14.10.10.4.3 step d) |
| Lifetime | The longer one of the lifetime of the stored forwarding information and the value of PREQ element field Lifetime | The longer one of the lifetime of the stored forwarding information and the value of PREQ element field Lifetime | The longer one of the lifetime of the stored forwarding information and the value of PREP element field Lifetime | The longer one of the lifetime of the stored forwarding information and the value of PREP element field Lifetime |

14.10.8.5 Repeated attempts at path discovery

Repeated attempts by a mesh STA at path discovery toward a single target shall be limited to dot11MeshHWMPmaxPREQretries. The minimum waiting time for the repeated attempt at path discovery to a single target is $2 \times \text{dot11MeshHWMPnetDiameterTraversalTime}$. For each attempt, the HWMP SN is incremented and a new Path Discovery ID is chosen.

14.10.8.6 Limiting the rate of HWMP SN increments

In order to improve path stability (and further reduce overhead), a mesh STA may use the same originator HWMP SN for a certain time interval. In this case, the originator HWMP SN shall not be incremented until at least `dot11MeshHWMPnetDiameterTraversalTime` has elapsed since the previous increment. This mechanism prevents mesh STAs from changing the path frequently to the originator mesh STA every time the originator mesh STA sends a burst of PREQ elements within a very short time. This element of the protocol allows an originator mesh STA to immediately initiate on-demand path discovery to a new target without affecting recently refreshed paths to the originator in other mesh STAs.

14.10.9 Path request (PREQ) mechanism

14.10.9.1 General

This subclause describes the function, generation, and processing of the PREQ element.

14.10.9.2 Function

The PREQ element, described in 9.4.2.113, is used for the following purposes:

- Discovering a path to one or more target mesh STAs
- Maintaining a path (optional)
- Building a proactive (reverse) path selection tree to the root mesh STA
- Confirming a path to a target mesh STA (optional)

14.10.9.3 Conditions for generating and sending a PREQ element

A mesh STA shall send a PREQ element in an HWMP Mesh Path Selection frame, as defined in 9.6.17.3, in the following cases:

Case A: Path Discovery (Original Transmission)

All of the following conditions apply:

- The mesh STA needs to establish an on-demand path to one or more targets for which there is no ongoing path discovery initiated by this mesh STA.
- The mesh STA has not sent a PREQ element for the target mesh STAs less than `dot11MeshHWMPpreqMinInterval` TUs ago. If this is the case, the transmission of the PREQ element has to be postponed until this condition becomes true.
- The mesh STA has not made more than (`dot11MeshHWMPmaxPREQretries` – 1) repeated attempts at path discovery toward the target of the PREQ element.

The content of a PREQ element in Case A shall be as shown in Table 14-10.

Table 14-10—Contents of a PREQ element in Case A

| Field | Value |
|---------------------------------|---|
| Element ID | Value given in Table 9-77 for the PREQ element |
| Length | $26 + N \times 11$ (if Bit 6 (AE subfield) in the Flags field = 0) $32 + N \times 11$ (if Bit 6 (AE subfield) in the Flags field = 1) |
| Flags | Bit 0: 0 (gate announcement not applicable) Bit 1: 0 (group addressed) Bit 2: 0 (no proactive PREP element applicable) Bit 3–5: Reserved Bit 6: (1 – if external address present, 0 – otherwise) Bit 7: Reserved |
| Hop Count | 0 |
| Element TTL | Maximum number of hops allowed for this element, e.g., dot11MeshHWMPnetDiameter. |
| Path Discovery ID | New unique Path Discovery ID, for instance, previous Path Discovery ID + 1 |
| Originator Mesh STA Address | MAC address of the path originator |
| Originator HWMP Sequence Number | Previous Originator HWMP SN + 1. See 14.10.8.6 |
| Originator External Address | Present only if Bit 6 in Flags field = 1. This value is set to the external address, which is the source address of the MSDU (from outside the mesh BSS) that triggered the path discovery at the originator. |
| Lifetime | The time for which mesh STAs receiving the PREQ element consider the forwarding information to be valid, e.g., dot11MeshHWMPactivePathTimeout. |
| Metric | Initial value of active path selection metric |
| Target Count | N ($N \geq 1$) |
| Per Target | Per Target Flags Bit 0 (TO): dot11MeshHWMPtargetOnly Bit 1: Reserved Bit 2 (USN): 0 if forwarding information for Target Address with valid HWMP SN exists, 1 otherwise Bit 3–7: Reserved |
| | Target Address MAC address of requested target |
| | Target HWMP Sequence Number If Per Target Flags Bit 2 (USN) is 0, the latest HWMP SN stored by the originator mesh STA for the target mesh STA from the forwarding information (see 14.10.8.4). Otherwise, reserved. |

Case B: Path Maintenance (Original Transmission) (optional)

All of the following conditions apply:

- The mesh STA has a path to a given target mesh STA that is not a root mesh STA.
- The last PREQ element to this target was sent dot11MeshHWMPmaintenanceInterval TUs (or more) ago.

The content of a PREQ element in Case B shall be as shown in Table 14-11.

Table 14-11—Contents of a PREQ element in Case B

| Field | Value | |
|---------------------------------|---|---|
| Element ID | Value given in Table 9-77 for the PREQ element | |
| Length | 26 + N × 11 | |
| Flags | Bit 0: 0 (gate announcement not applicable) Bit 1: 0 (group addressed) Bit 2: 0 (no proactive PREP element applicable) Bit 3–5: Reserved Bit 6: 0 (no address extension) Bit 7: Reserved | |
| Hop Count | 0 | |
| Element TTL | Maximum number of hops allowed for this element, e.g., dot11MeshHWMPnetDiameter | |
| Path Discovery ID | New unique Path Discovery ID, for instance, previous Path Discovery ID + 1 | |
| Originator Mesh STA Address | MAC address of the originator of the PREQ element | |
| Originator HWMP Sequence Number | Originator HWMP SN + 1. See 14.10.8.6 | |
| Originator External Address | Field not present | |
| Lifetime | The time for which mesh STAs receiving the PREQ element consider the forwarding information to be valid, e.g., dot11MeshHWMPactivePathTimeout. | |
| Metric | Initial value of active path selection metric | |
| Target Count | N (N ≥ 1) | |
| Per Target | Per Target Flags | Bit 0 (TO): 1 (target only) Bit 1: Reserved Bit 2 (USN): 0 Bit 3–7: Reserved |
| | Target Address | MAC Address of target mesh STA |
| | Target HWMP Sequence Number | The latest HWMP SN for this target known to the originator mesh STA. |

Case C: Proactive PREQ element (Original Transmission)

All of the following conditions apply:

- The root mesh STA is configured as root mesh STA using proactive PREQ elements ([dot11MeshHWMProotMode = proactivePREQnoPREP (2)] OR [dot11MeshHWMProotMode = proactivePREQwithPREP (3)]).
- The root mesh STA sent its previous proactive PREQ element dot11MeshHWMProotInterval TUs ago.

The contents of a PREQ element in Case C shall be as shown in Table 14-12.

Table 14-12—Contents of a PREQ element in Case C

| Field | Value | |
|---------------------------------|--|---|
| Element ID | Value given in Table 9-77 for the PREQ element | |
| Length | 37 | |
| Flags | Bit 0: 1 if dot11MeshGateAnnouncements is true (gate announcement), 0 otherwise Bit 1: 0 (group addressed) Bit 2: 0 if dot11MeshHWMProotMode = proactivePREQnoPREP(2), 1 if dot11MeshHWMProotMode = proactivePREQwithPREP(3) (proactive PREP) Bit 3–5: Reserved Bit 6: 0 (no address extension) Bit 7: Reserved | |
| Hop Count | 0 | |
| Element TTL | Maximum number of hops allowed for this element, e.g., dot11MeshHWMPnetDiameter. | |
| Path Discovery ID | New unique Path Discovery ID, for instance, previous Path Discovery ID + 1 | |
| Originator Mesh STA Address | MAC address of the root mesh STA | |
| Originator HWMP Sequence Number | Originator HWMP SN + 1. See 14.10.8.6 | |
| Originator External Address | Field not present | |
| Lifetime | dot11MeshHWMPactivePathToRootTimeout | |
| Metric | Initial value of active path selection metric | |
| Target Count | 1 | |
| Per Target | Per Target Flags | Bit 0 (TO): 1 Bit 1: Reserved Bit 2 (USN): 1 Bit 3–7: Reserved |
| | Target Address | Broadcast address |
| | Target HWMP Sequence Number | 0 |

Case D: Root Path Confirmation (Original Transmission)

One of the following conditions applies:

- The mesh STA has received a RANN element and the metric (RANN metric \oplus metric to the transmitter of the RANN element) is better than the metric to the root in the current forwarding information.
- The mesh STA has a path to a root mesh STA and the last PREQ element to the root mesh STA was sent dot11MeshHWMPconfirmationInterval TUs (or more) ago.

The content of a PREQ element in Case D shall be as shown in Table 14-13.

Table 14-13—Contents of a PREQ element in Case D

| Field | Value | |
|---------------------------------|--|---|
| Element ID | Value given in Table 9-77 for the PREQ element | |
| Length | As required | |
| Flags | Bit 0: 0 (gate announcement not applicable) Bit 1: 1 (individually addressed) Bit 2: 0 (no proactive PREP element applicable) Bit 3–5: Reserved Bit 6: 0 (no address extension) Bit 7: Reserved | |
| Hop Count | 0 | |
| Element TTL | Maximum number of hops allowed for this element, e.g., dot11MeshHWMPnetDiameter | |
| Path Discovery ID | Not used | |
| Originator Mesh STA Address | MAC address of the originator mesh STA | |
| Originator HWMP Sequence Number | Originator HWMP SN + 1. See 14.10.8.6 | |
| Originator External Address | Field not present | |
| Lifetime | The time for which mesh STAs receiving the PREQ element consider the forwarding information to be valid, e.g., dot11MeshHWMPactivePathToRootTimeout. | |
| Metric | Initial value of active path selection metric | |
| Target Count | 1 | |
| Per Target | Per Target Flags | Bit 0 (TO): 1 Bit 1: Reserved Bit 2 (USN): 0 Bit 3–7: Reserved |
| | Target Address | Root mesh STA MAC Address |
| | Target HWMP Sequence Number | The latest HWMP SN for this target known to the originator mesh STA |

Case E: PREQ element Propagation

Case E1 (target count = 1, no PREP element generation as intermediate mesh STA):

All of the following conditions apply:

- The mesh STA has received and accepted a PREQ element—see 14.10.9.4.2.
- dot11MeshForwarding is true.
- [The active forwarding information for the Originator Mesh STA was created or updated according to the rules defined in 14.10.8.4] OR [{the Originator HWMP SN of the accepted PREQ element = HWMP SN in the forwarding information for this originator mesh STA} AND {the mesh STA has not previously received a PREQ element with the same Originator Mesh STA Address and the same Path Discovery ID}].
- The Element TTL field is greater than 1—see 14.10.8.2.
- Target Count = 1.
- [The mesh STA is not the target of the PREQ element)]
 OR
 [the target of the PREQ element is the MAC broadcast address (all 1s)].
- The mesh STA is not the proxy of the target address.
- [The TO (Target Only) subfield of the target in the PREQ element is set (TO = 1)]
 OR
 [{the TO (Target Only) subfield of the target in the PREQ element is not set (TO = 0)} AND {mesh STA has no active forwarding information for the requested target}].

The content of a PREQ element in Case E1 shall be as shown in Table 14-14.

Table 14-14—Contents of a PREQ element in Case E1

| Field | Value |
|---------------------------------|---|
| Element ID | Value given in Table 9-77 for the PREQ element |
| Length | As received |
| Flags | As received |
| Hop Count | As received + 1 |
| Element TTL | As received – 1 |
| Path Discovery ID | As received |
| Originator Mesh STA Address | As received |
| Originator HWMP Sequence Number | As received |
| Originator External Address | As received. This field is present if Bit 6 of the Flags field (AE subfield) is 1; it is not present otherwise. |
| Lifetime | As received |
| Metric | As received \oplus own metric toward transmitter of received PREQ element |
| Target Count | 1 |

Table 14-14—Contents of a PREQ element in Case E1 (continued)

| Field | Value |
|------------|--|
| Per Target | Per Target Flags As received |
| | Target MAC Address As received |
| | Target HWMP Sequence Number As received |

Case E2 (target count = 1, PREP element generation as intermediate mesh STA):

All of the following conditions apply:

- The mesh STA has received and accepted a PREQ element—see 14.10.9.4.2.
- dot11MeshForwarding is true.
- [The active forwarding information for the Originator Mesh STA was created or updated according to the rules defined in 14.10.8.4]
OR
[{the Originator HWMP SN of the accepted PREQ element = HWMP SN in the forwarding information for this originator mesh STA} AND {the mesh STA has not previously received a PREQ element with the same Originator Mesh STA Address and the same Path Discovery ID}].
- The Element TTL field is greater than 1—see 14.10.8.2.
- Target Count = 1.
- The mesh STA is not the target of the PREQ element.
- The mesh STA is not the proxy of the target address.
- The mesh STA has active forwarding information for the requested target.
- [The TO (Target Only) subfield of the target in the PREQ element is not set (TO = 0)]
AND
[the mesh STA has active forwarding information for the requested target].

The contents of a PREQ element in Case E2 shall be as shown in Table 14-15.

Table 14-15—Contents of a PREQ element in Case E2

| Field | Value |
|---------------------------------|--|
| Element ID | Value given in Table 9-77 for the PREQ element |
| Length | As received |
| Flags | As received |
| Hop Count | As received + 1 |
| Element TTL | As received – 1 |
| Path Discovery ID | As received |
| Originator Mesh STA Address | As received |
| Originator HWMP Sequence Number | As received |

Table 14-15—Contents of a PREQ element in Case E2 (continued)

| Field | Value | |
|-----------------------------|---|--|
| Originator External Address | As received. This field is present if Bit 6 of the Flags field (AE subfield) is 1; it is not present otherwise. | |
| Lifetime | As received | |
| Metric | As received \oplus own metric toward transmitter of received PREQ element | |
| Target Count | 1 | |
| Per Target | Per Target Flags | Bit 0 (TO): 1 (target only because mesh STA sent a PREP element) Bit 1: Reserved Bit 2 (USN): As received Bit 3–7: Reserved |
| | Target MAC Address | As received |
| | Target HWMP Sequence Number | As received |

Case E3 (target count > 1):

All of the following conditions apply:

- The mesh STA has received and accepted a PREQ element—see 14.10.9.4.2.
- dot11MeshForwarding is true.
- [The active forwarding information for the Originator Mesh STA was created or updated according to the rules defined in 14.10.8.4
OR
[{the Originator HWMP SN of the accepted PREQ element = HWMP SN in the forwarding information for this originator mesh STA} AND {the mesh STA has not previously received a PREQ element with the same Originator Mesh STA Address and the same Path Discovery ID}].
- The Element TTL field is greater than 1—see 14.10.8.2.
- Target Count > 1.
- There is at least one requested target that is neither the recipient MAC address nor an external MAC address proxied by the recipient.

The contents of a PREQ element in Case E3 shall be as shown in Table 14-16.

Table 14-16—Contents of a PREQ element in Case E3

| Field | Value |
|-------------|--|
| Element ID | Value given in Table 9-77 for the PREQ element |
| Length | 26 + N × 11 |
| Flags | As received |
| Hop Count | As received + 1 |
| Element TTL | As received – 1 |

Table 14-16—Contents of a PREQ element in Case E3 (continued)

| Field | Value | |
|---------------------------------|---|--|
| Path Discovery ID | As received | |
| Originator Mesh STA Address | As received | |
| Originator HWMP Sequence Number | As received | |
| Originator External Address | As received. This field is present if Bit 6 of the Flags field (AE subfield) is set to 1; it is not present otherwise. | |
| Lifetime | As received | |
| Metric | As received \oplus own metric toward the transmitter of the received PREQ element | |
| Target Count | $1 \leq \text{target count} \leq \text{received target count}$ received target count less the number of requested destinations, for which the processing mesh STA <ul style="list-style-type: none"> — is the target mesh STA or — is the target proxy mesh gate | |
| Per Target #A | Per Target Flags #A | As received |
| | Target MAC Address #A | As received |
| | Target HWMP Sequence Number #A | As received |
| Per Target #B | Per Target Flags #B | Bit 0 (TO): 1 (target only because mesh STA sent PREP element) Bit 1: As received Bit 2 (USN): As received Bit 3–7: As received |
| | Target MAC Address #B | As received |
| | Target HWMP Sequence Number #B | As received |

For the per target fields (Per Target Flags, Target Address, Target HWMP Sequence Number) assume the following:

- Target #A: If target A would have been the only requested target, it would generate a PREQ element for propagation according to case E1.
- Target #B: If target B would have been the only requested target, it would generate a PREQ element for propagation according to case E2.

14.10.9.4 PREQ element processing

14.10.9.4.1 General

Received PREQ elements are subject to certain acceptance criteria. Processing and actions taken depend on the contents of the PREQ element and the information available to the receiving mesh STA. See also 14.10.8.

14.10.9.4.2 Acceptance criteria

The PREQ element shall not be accepted (and shall not be processed as described in 14.10.9.4.3) if any of the following is true:

- (The target address of the PREQ element is neither the recipient MAC address, broadcast address, nor an external MAC address proxied by the recipient) AND (dot11MeshForwarding is false)
- (Bit 1 (Addressing Mode subfield) of the Flags field in the PREQ element is equal to 1) AND (there is no valid forwarding information with the destination mesh STA address equal to the Target Address of the PREQ element)

Otherwise, the PREQ element is accepted. See also 14.10.8.

14.10.9.4.3 Effect of receipt

A mesh STA receiving a PREQ element according to the acceptance criteria in 14.10.9.4.2 shall record the Path Discovery ID and the Originator Mesh STA Address. The receiving mesh STA shall create or update the active forwarding information it maintains for the originator mesh STA of the PREQ element according to the rules defined in 14.10.8.4.

If the active forwarding information for the Originator Mesh STA was created or updated according to the rules defined in 14.10.8.4 or if the Target HWMP SN of the PREQ element is the same as the HWMP SN in the forwarding information for the Target Mesh STA and there has been no record of the Originator Mesh STA and Path Discovery ID, the following applies:

- a) If the mesh STA is the target of the PREQ element or is the proxy of the target MAC address it shall initiate the transmission of a PREP element to the originator mesh STA (14.10.10.3 Case A). If the PREQ element carries an external address (indicated by the AE subfield in the Flags field), the mesh STA shall update its proxy information with the Originator External Address as external address, the PREQ element Originator Mesh STA Address as the corresponding proxy, the HWMP Sequence Number as proxy information sequence number, and for the proxy lifetime the longer one of the value of the PREQ element Lifetime field and the proxy lifetime if the proxy information already exists (see also 14.11.4.3).
- b) If step a) was not applicable for the mesh STA and the AE subfield in the Flags field in the PREQ element is 1, the mesh STA may update its proxy information with the Originator External Address as external address, the PREQ element Originator Mesh STA Address as the corresponding proxy, the HWMP Sequence Number as proxy information sequence number, and for the proxy lifetime the longer one of the value of the PREQ element Lifetime field and the proxy lifetime if the proxy information already exists (see also 14.11.4.3).
- c) If the mesh STA has valid forwarding information to any of the requested targets and the TO (Target Only) subfield for such a target is not set (TO = 0), it initiates the transmission of a PREP element for each of these targets (see 14.10.10.3 Case C).
- d) If the mesh STA is initiating a PREP element transmission on behalf of another target according to step c) (intermediate reply), it shall process all of the following:
 - Update the precursor list in its forwarding information for the target mesh STA with the next hop from the forwarding information of the originator mesh STA.

- Update the lifetime for this precursor that is the longer one of the lifetime of the forwarding information of the target mesh STA.
 - Update the lifetime of the precursor list entry in case it already exists.
 - Update the precursor list in its forwarding information for the originator mesh STA with the next hop toward the target mesh STA.
 - Update the lifetime for this precursor that is the longer one of the lifetime of the forwarding information of the originator mesh STA.
 - Update the lifetime of the precursor list entry in case it already exists.
- e) If the received PREQ element is a proactive PREQ element [target address is set to all 1s, TO subfield is set (TO = 1)], the mesh STA generates a proactive PREP element to the root mesh STA (see 14.10.10.3 Case D) depending on the setting of the Proactive PREP subfield. If the Proactive PREP subfield is 1, a proactive PREP element is generated, if it is 0, a proactive PREP element is generated only if a bidirectional path to the root mesh STA is required (see S.6).
- f) If there are individually addressed targets in the PREQ element that have not been processed in step a) or that have been processed in step c) or in step e), the receiving mesh STA shall propagate the PREQ element as defined in 14.10.9.3 Case E.

14.10.10 Path reply (PREP) mechanism

14.10.10.1 General

Subclause 14.10.10 describes the function, generation, and processing of the PREP element.

14.10.10.2 Function

The PREP element is transmitted in individually addressed frames and is described in 9.4.2.114. The purpose of the PREP element is as follows:

- To establish the forward path to a target mesh STA or target proxy mesh gate.
- To confirm the reverse path to the originator.

14.10.10.3 Conditions for generating and sending a PREP element

A mesh STA sends out a PREP element in an HWMP Mesh Path Selection frame, as defined in 9.6.17.3, in the following cases:

Case A: Path Discovery (Original Transmission)

A PREP element is transmitted if the mesh STA has received and accepted a PREQ element (see 14.10.9.4.2) fulfilling any one of the following conditions:

- The Target Address of the PREQ element is the same as MAC address of the receiving mesh STA.
- The Target Address of the PREQ element is an external address currently proxied by the mesh STA.

The content of the generated PREP element in Case A shall be as shown in Table 14-17.

Table 14-17—Contents of a PREP element in Case A

| Field | Value |
|---------------------------------|--|
| Element ID | Value given in Table 9-77 for the PREP element |
| Length | As required |
| Flags | Bit 0–5: Reserved Bit 6 (AE): (1 = external address present, 0 = otherwise) Bit 7: Reserved |
| Hop Count | 0 |
| Element TTL | Maximum number of hops allowed for this element |
| Target Mesh STA Address | MAC address of the target mesh STA or target proxy mesh gate |
| Target HWMP Sequence Number | HWMP SN of the target mesh STA or target proxy mesh gate after it has been updated according to 14.10.8.3 |
| Target External Address | External target address on behalf of which the PREP element is sent. Present only if Bit 6 (AE subfield) in the Flags field is 1 |
| Lifetime | As per the PREQ element that triggered the transmission of this PREP element |
| Metric | Initial value of active path selection metric |
| Originator Mesh STA Address | MAC address of the originator mesh STA |
| Originator HWMP Sequence Number | HWMP SN of the originator mesh STA |

Case B: PREP element propagation

A PREP element is propagated if all of the following conditions apply:

- The mesh STA has received and accepted the PREP element—see 14.10.10.4.2.
- The mesh STA is not the path originator.

The contents of a PREP element in Case B shall be as shown in Table 14-18.

Table 14-18—Contents of a PREP element in Case B

| Field | Value |
|-----------------------------|--|
| Element ID | Value given in Table 9-77 for the PREP element |
| Length | As received |
| Flags | As received |
| Hop Count | As received + 1 |
| Element TTL | As received – 1 |
| Target Mesh STA Address | As received |
| Target HWMP Sequence Number | As received |
| Target External Address | As received |

Table 14-18—Contents of a PREP element in Case B (continued)

| Field | Value |
|---------------------------------|--|
| Lifetime | As received |
| Metric | As received \oplus own metric toward the transmitting mesh STA |
| Originator Mesh STA Address | As received |
| Originator HWMP Sequence Number | As received |

Case C: Intermediate reply (Original Transmission)

A PREP element is transmitted if the mesh STA has received a PREQ element fulfilling all of the following conditions:

- The TO (Target Only) subfield in the corresponding Per Target Flags field in the PREQ element is not set (TO = 0)
- The receiving mesh STA has active forwarding information with
 - a) A destination that is the same as the Target Address of the PREQ element
 - b) An HWMP SN that is greater than or equal to the Target HWMP SN of the PREQ element
 - c) A nonzero lifetime

The content of the generated PREP element in Case C shall be as shown in Table 14-19.

Table 14-19—Contents of a PREP element in Case C

| Field | Value |
|---------------------------------|--|
| Element ID | Value given in Table 9-77 for the PREP element |
| Length | 31 |
| Flags | Bit 0–5: Reserved Bit 6 (AE): 0 Bit 7: Reserved |
| Hop Count | 0 |
| Element TTL | Maximum number of hops allowed for this element |
| Target Mesh STA Address | Target MAC address from the PREQ element |
| Target HWMP Sequence Number | HWMP SN of the stored forwarding information of the Target of the PREQ element |
| Target External Address | Not present |
| Lifetime | As per the PREQ element that triggered the transmission of this PREP element |
| Metric | Value of path metric taken from the active forwarding information for the target address of the PREQ element |
| Originator Mesh STA Address | MAC address of the originator mesh STA |
| Originator HWMP Sequence Number | HWMP SN of the originator mesh STA |

Case D: Proactive PREP element in Proactive PREQ element mode (Original Transmission)

One of the following conditions applies:

- The mesh STA has received a proactive PREQ element with the Proactive PREP subfield set to 0 AND the mesh STA needs to establish or update a bidirectional path to the root mesh STA.
- The mesh STA has received a proactive PREQ element with the Proactive PREP subfield set to 1.

Note that a proactive PREQ element is a PREQ element with a Target Address set to all 1s and its TO subfield set (TO=1).

The content of the generated PREP element in Case D shall be as shown in Table 14-20.

Table 14-20—Contents of a PREP element in Case D

| Field | Value |
|---------------------------------|---|
| Element ID | Value given in Table 9-77 for the PREP element |
| Length | 31 |
| Flags | Bit 0–5: Reserved Bit 6 (AE): 0 Bit 7: Reserved |
| Hop Count | 0 |
| Element TTL | Maximum number of hops allowed for this element |
| Target Mesh STA Address | MAC address of the mesh STA |
| Target HWMP Sequence Number | HWMP SN of the mesh STA |
| Target External Address | Not present |
| Lifetime | Lifetime of the PREQ element that triggered the transmission of this PREP element |
| Metric | Initial value of active path selection metric |
| Originator Mesh STA Address | MAC address of the root mesh STA (originator mesh STA of the PREQ element) |
| Originator HWMP Sequence Number | HWMP SN of the root mesh STA (originator HWMP SN of the PREQ element) |

14.10.10.4 PREP element processing

14.10.10.4.1 General

Received PREP elements are subject to certain acceptance criteria. Processing and actions taken depend on the contents of the PREP element and the information available to the receiving mesh STA.

14.10.10.4.2 Acceptance criteria

The PREP element shall not be accepted (and shall not be processed as described in 14.10.10.4.3) if any of the following is true:

- (The Originator Mesh STA Address of the PREP element is neither the recipient MAC address nor an external MAC address proxied by the recipient) AND (dot11MeshForwarding is false).

Otherwise, the PREP element shall be accepted.

14.10.10.4.3 Effect of receipt

A mesh STA receiving a PREP element according to the acceptance criteria in 14.10.10.4.2 shall create or update the active forwarding information it maintains for the target mesh STA of the PREP element (according to the rules defined in 14.10.8.4). If the conditions for creating or updating the forwarding information have not been met in those rules, no further steps are applied to the PREP element.

If the active forwarding information was created or updated according to the rules defined in 14.10.8.4, the following apply:

- a) If the receiving mesh STA is not the final destination of the PREP element (originator mesh STA) and the field Element TTL > 1, the PREP element is propagated as defined in 14.10.10.3 Case B.
- b) If the receiving mesh STA is the final destination of the PREP element (originator mesh STA) and its AE subfield in the Flags field is 1, the mesh STA shall store the Target External Address, the Target Mesh STA Address, and the HWMP Sequence Number as proxy information sequence number in its proxy information. The proxy lifetime is the longer one of the value of the PREP element Lifetime field and the proxy lifetime if the proxy information already exists (see also 14.11.4.3).
- c) If the receiving mesh STA is not the final destination of the PREP element (originator mesh STA) and its AE subfield in the Flags field is 1, the mesh STA may store the Target External Address, the Target Mesh STA Address, and the HWMP Sequence Number as proxy information sequence number in its proxy information. The proxy lifetime is the longer one of the value of the PREP element Lifetime field and the proxy lifetime if the proxy information already exists (see also 14.11.4.3).
- d) If the mesh STA propagates the PREP element, the precursor list for the Target Mesh STA Address is updated by adding the next-hop mesh STA to which the PREP element is propagated. In addition, at the mesh STA the precursor list for the originator mesh STA address is updated by adding the next-hop mesh STA toward the Target Address. The lifetimes of these entries in the precursor lists are the values of the lifetimes of the corresponding forwarding information.

14.10.11 Path error (PERR) mechanism

14.10.11.1 General

Subclause 14.10.11 describes the function, generation, and processing of the PERR element.

14.10.11.2 Function

The PERR element is used for announcing one or more unreachable destination(s). The announcement is sent to all traffic sources that have a known active path to the destination(s). The active forwarding information associated with the unreachable destination(s) should no longer be used for forwarding.

A PERR element may be either group addressed (if there are many precursors), individually addressed (if there is only one precursor), or individually addressed iteratively to all precursors (see 14.10.7, item “PERR element individually addressed”). The PERR element is processed as a single element when iteratively individually addressed to several precursors. The PERR element contains the destinations that are unreachable.

A PERR element is propagated by mesh STAs receiving a PERR element if certain conditions are met.

A mesh STA generating or receiving a PERR element may attempt to establish paths to unreachable destinations using any of the available HWMP mechanisms.

14.10.11.3 Conditions for generating and sending a PERR element

A mesh STA shall send out a PERR element in an HWMP Mesh Path Selection frame, as defined in 9.6.17.3, in the following cases:

Case A: Original transmission (next hop is unusable)

The mesh STA has not sent a PERR element less than dot11MeshHWMPperrMinInterval TUs ago, and the following condition applies:

- The mesh STA determines that the link to the next hop of an active path in its forwarding information is no longer usable.

NOTE—The detection might be triggered by the fact that a mesh STA is unable to forward an MSDU/MMPDU to a next-hop mesh STA.

The HWMP SN in the forwarding information of all unreachable destinations announced in this PERR element is incremented by 1. The forwarding information for each unreachable destination announced in this PERR element is invalidated.

The contents of a PERR element in Case A shall be as shown in Table 14-21.

Table 14-21—Contents of a PERR element in Case A

| Field | Value |
|-------------------------|---|
| Element ID | Value given in Table 9-77 for the PERR element |
| Length | $2 + N \times 13$ |
| Element TTL | The maximum number of hops the element is propagated before being discarded. |
| Number of Destinations | Number of announced unreachable destinations in the PERR element. |
| Flags #1 | Bit 0–5: Reserved Bit 6 (AE): 0 Bit 7: Reserved |
| Destination Address #1 | MAC address of unreachable destination #1. |
| HWMP Sequence Number #1 | HWMP SN for Destination Address #1 from the forwarding information after above increment. |
| Reason Code #1 | “MESH-PATH-ERROR-DESTINATION-UNREACHABLE” (see 9.4.1.7). |
| ... | ... |

Case B: Original transmission (missing forwarding information)

The mesh STA has not sent a PERR element less than dot11MeshHWMPperrMinInterval TUs ago, and one of the following conditions applies:

- The mesh STA receives an individually addressed frame with a destination address not matching its own MAC address for which it has no forwarding information.
- The mesh STA receives an individually addressed frame with a destination address not matching its own MAC address and dot11MeshForwarding is false.

The contents of a PERR element in Case B shall be as shown in Table 14-22.

Table 14-22—Contents of a PERR element in Case B

| Field | Value |
|-------------------------|--|
| Element ID | Value given in Table 9-77 for the PERR element. |
| Length | $2 + N \times 13$ |
| Element TTL | The maximum number of hops the element is propagated before being discarded. |
| Number of Destinations | Number of announced destinations with missing forwarding information in the PERR element. |
| Flags #1 | Bit 0–5: Reserved Bit 6 (AE): 0 Bit 7: Reserved |
| Destination Address #1 | MAC address of destination with missing forwarding information #1. This is Address 3 of the received individually addressed frame. |
| HWMP Sequence Number #1 | Reserved |
| Reason Code #1 | “MESH-PATH-ERROR-NO-FORWARDING-INFORMATION” (see 9.4.1.7). |
| ... | ... |

Case C: Original transmission (proxy information is unusable)

The mesh STA has not sent a PERR element less than dot11MeshHWMPperrMinInterval TUs ago, and the following condition applies:

- The mesh STA is a proxy mesh gate and determines that an active proxy information where the mesh STA is the proxy mesh gate is no longer usable.

The contents of a PERR element in Case C shall be as shown in Table 14-23.

Table 14-23—Contents of a PERR element in Case C

| Field | Value |
|---------------------------------|---|
| Element ID | Value given in Table 9-77 for the PERR element. |
| Length | $2 + N \times 19$ |
| Element TTL | The maximum number of hops the element is propagated before being discarded. |
| Number of Destinations | Number of announced unreachable external destinations in the PERR element. |
| Flags #1 | Bit 0–5: Reserved Bit 6 (AE): 1 Bit 7: Reserved |
| Destination Address #1 | MAC address of proxy mesh gate #1 with unusable active proxy information. |
| HWMP Sequence Number #1 | Last used HWMP SN for Destination Address #1. |
| Destination External Address #1 | External MAC address of the active proxy information that is not longer usable and for which the mesh STA is the proxy mesh gate. |
| Reason Code #1 | “MESH-PATH-ERROR-NO-PROXY-INFORMATION” (see 9.4.1.7.) |
| ... | ... |

Case D: PERR element propagation

The mesh STA has not sent a PERR element less than dot11MeshHWMPperrMinInterval TUs ago, and all of the following conditions apply:

- The mesh STA received a PERR element from a neighbor peer mesh STA.
- A destination in the PERR element is the same as one of the destinations in the active forwarding information of the mesh STA where the next hop is the transmitter of the received PERR element, and the forwarding information or the proxy information has been invalidated according to conditions in 14.10.11.4.3 case b), case c), or case d).
- dot11MeshForwarding is true.
- The Element TTL field in the received PERR element is greater than 1.

The contents of a PERR element in Case D shall be as shown in Table 14-24.

Table 14-24—Contents of a PERR element in Case D

| Field | Value |
|---------------------------------|---|
| Element ID | Value given in Table 9-77 for the PERR element |
| Length | if AE subfield = 0: $2 + N \times 13$ if AE subfield = 1: $2 + N \times 19$ |
| Element TTL | Element TTL in received PERR element – 1 |
| Number of Destinations | $1 \leq$ number of destinations in the PERR element \leq received value Received number of destinations less the number of received destinations for which the transmitter of the PERR element is not the next hop |
| Flags #1 | As received |
| Destination Address #1 | MAC address of unreachable destination #1, as received |
| HWMP Sequence Number #1 | If Reason Code #1 = “MESH-PATH-ERROR-NO-FORWARDING-INFORMATION” and received value = 0, then HWMP SN for Destination Address #1 from the forwarding information after the increment of 14.10.10.4.3 step b). Otherwise, as received. |
| Destination External Address #1 | As received This field is present if Bit 6 (AE subfield) of the Flags field #1 is 1; it is not present otherwise. |
| Reason Code #1 | As received |
| ... | ... |

14.10.11.4 PERR element processing

14.10.11.4.1 General

Received PERR elements are subject to certain acceptance criteria. Processing and actions taken depend on the contents of the PERR element and the information available to the receiving mesh STA. See also 14.10.8.

14.10.11.4.2 Acceptance criteria

The PERR element shall be accepted (and shall be processed as described in 14.10.11.4.3) if the following applies:

- The mesh STA that receives the PERR element has forwarding information stored where
 - The destination is contained in the list of unreachable destinations of the PERR element and
 - The next hop is the transmitter of the received PERR element

Otherwise, the PERR element shall be discarded.

14.10.11.4.3 Effect of receipt

The following applies only to a PERR element that was accepted according to the acceptance criteria in 14.10.11.4.2:

- a) The mesh STA creates a list of unreachable destinations consisting of those destinations from the received PERR element for which the next hop in the local active forwarding information is the transmitter of the PERR element. Step b) through step e) are applied to the destinations in this list.
- b) If the Reason Code is “MESH-PATH-ERROR-NO-FORWARDING-INFORMATION” and the HWMP Sequence Number is 0, the receiving mesh STA increments the HWMP SN in the forwarding information of the listed unreachable destination by 1 and invalidates the forwarding information.
- c) If the Reason Code is “MESH-PATH-ERROR-NO-FORWARDING-INFORMATION” and the HWMP Sequence Number is not 0 or the Reason Code is “MESH-PATH-ERROR-DESTINATION-UNREACHABLE” and the received HWMP SN for a listed unreachable destination is higher than the current HWMP SN in the forwarding information for that destination, the receiving mesh STA shall consider that destination unreachable and shall set the HWMP SN in the forwarding information to the HWMP SN received in the PERR element and shall invalidate the forwarding information associated with this unreachable destination.
- d) If the Reason Code is “MESH-PATH-ERROR-NO-PROXY-INFORMATION,” the receiving mesh STA shall consider the corresponding Destination External Address unreachable and shall invalidate the proxy information associated with this unreachable external destination (proxy mesh gate is the Destination Address of the PERR element, external MAC address is the Destination External Address of the PERR element, proxy information sequence number is the HWMP Sequence Number).
- e) A PERR element is propagated according to the conditions defined in 14.10.11.3 Case D “PERR element propagation.”

14.10.12 Root announcement (RANN) mechanism

14.10.12.1 General

Subclause 14.10.12 describes the function, generation, and processing of the RANN element.

14.10.12.2 Function

The RANN element, described in 9.4.2.112, is used for announcing the presence of a mesh STA configured as root mesh STA using the proactive RANN mechanism. RANN elements are sent out periodically by the root mesh STA.

The RANN element propagates path metric information across the network so that each mesh STA can select a best metric path to the announced root mesh STA. This mechanism allows bidirectional trees to be built, using a robust procedure based on individually addressed frames initiated by the mesh STAs. This procedure makes the root mesh STA aware of all mesh STAs.

A receiving mesh STA shall propagate the RANN element as described in 14.10.12.3 Case B.

14.10.12.3 Conditions for generating and sending a RANN element

A mesh STA sends out a RANN element in an HWMP Mesh Path Selection frame, as defined in 9.6.17.3, in the following cases:

Case A: Original transmission

All of the following conditions apply:

- The mesh STA is configured as a root mesh STA using the proactive RANN mechanism [dot11MeshHWMProotMode = rann (4)].
- The root mesh STA sent its previous RANN element dot11MeshHWMPrannInterval TUs ago.

The contents of a RANN element in Case A shall be as shown in Table 14-25.

Table 14-25—Contents of a RANN element in Case A

| Field | Value |
|-----------------------|---|
| Element ID | Value given in Table 9-77 for the RANN element |
| Length | 21 |
| Flags | Bit 0: set to 1 if dot11MeshGateAnnouncements is true, set to 0 otherwise. Bit 1–7: Reserved |
| Hop Count | 0 |
| Element TTL | Maximum number of hops allowed for this element |
| Root Mesh STA Address | MAC address of the root mesh STA |
| HWMP Sequence Number | Last used HWMP SN of the root mesh STA + 1 |
| Interval | dot11MeshHWMPrannInterval |
| Metric | Initial value of active path selection metric |

Case B: Propagation

All of the following conditions apply:

- The mesh STA has valid forwarding information to a root mesh STA using the proactive RANN mechanism [dot11MeshHWMProotMode = rann (4)].
- The mesh STA sent its previous RANN element dot11MeshHWMPrannInterval TUs ago.
- dot11MeshForwarding is true.
- The Element TTL field is greater than 1—see 14.10.8.2.

The contents of a RANN element in Case B shall be as shown in Table 14-26.

Table 14-26—Contents of a RANN element in Case B

| Field | Value |
|-----------------------|---|
| Element ID | Value given in Table 9-77 for the RANN element |
| Length | As received |
| Flags | As received |
| Hop Count | As received + 1 |
| Element TTL | As received – 1 |
| Root Mesh STA Address | As received |
| HWMP Sequence Number | As received |
| Interval | As received |
| Metric | As received \oplus own link metric toward the transmitting mesh STA |

14.10.12.4 RANN element reception

14.10.12.4.1 General

Received RANN elements are subject to certain acceptance criteria. Processing and actions taken depend on the content of the RANN element and the forwarding information maintained by the receiving mesh STA. See also 14.10.8.

14.10.12.4.2 Acceptance criteria

The RANN element shall not be accepted (and shall not be processed as described in 14.10.12.4.3) if any of the following is true:

- The HWMP Sequence Number < previous HWMP SN from this originating root mesh STA
- (The HWMP Sequence Number = previous HWMP SN) AND (updated path metric is *worse than* previous path metric)

Otherwise, the RANN element shall be accepted.

14.10.12.4.3 Effect of receipt

The following applies only to a RANN element that was accepted according to the acceptance criteria in 14.10.12.4.2:

- a) The receiving mesh STA shall set dot11MeshHWMPrrnInterval to the value of the Interval field of the received RANN element.
- b) The receiving mesh STA may initiate a PREQ element / PREP element exchange with the root mesh STA to set up or update a path to the root mesh STA. See 14.10.9.3 Case D.
- c) The receiving mesh STA may record the Root Mesh STA Address, together with the HWMP Sequence Number, Hop Count, and Metric in order to assist in executing 14.10.9.3 Case D.

The receiving mesh STA shall transmit a RANN element if the conditions defined in 14.10.12.3 Case B are true.

14.10.13 Considerations for support of STAs without mesh functionality

The verification, by the mesh STA collocated with the AP, of disjunct MAC addresses between a non-AP STA without mesh functionality and mesh STAs during authentication/association of the non-AP STA without mesh functionality (see 11.3.6) may be done by issuing a PREQ element for the MAC address of the non-AP STA without mesh functionality by the mesh STA collocated with the AP. The TO (Target Only) subfield of the Per Target Flags field of the PREQ element shall be set to 1.

The MAC address of the non-AP STA already exists in the MBSS if the AP with mesh functionality receives a PREP element for the MAC address of the non-AP STA and it can be derived from the PREP element that the requested MAC address is originated from a mesh STA. (The AE subfield of the Flags field of the PREP element is set to 0; see 9.4.2.114.)

14.11 Interworking with the DS

14.11.1 Overview of interworking between a mesh BSS and a DS

A mesh STA that has access to a DS is called a *mesh gate*. Mesh STAs in an MBSS access the DS via the mesh gate. An MBSS functions like an IEEE 802 LAN segment that is compatible with IEEE Std 802.1D. The MBSS appears as a single access domain.

An MBSS may contain two or more mesh gates. When multiple mesh gates in an MBSS have access to the same DS, the MBSS has more than one “port” (in the sense of IEEE Std 802.1D-2004, for example) through which it accesses the DS. Accordingly, broadcast loops may occur. Therefore, mesh gates should implement a loop preventing protocol in the DS.

NOTE—In the DS a typical implementation uses the Rapid Spanning Tree Protocol (RSTP) as specified in IEEE Std 802.1D-2004. With RSTP the resulting active DS topology forms a tree. Then, even if multiple mesh gates connect with the same DS, the MBSS only accesses the DS through a single mesh gate.

When dot11MeshGateAnnouncements is true, the mesh gate announces its presence to other mesh STAs in the MBSS. The mesh gate uses the gate announcement protocol (see 14.11.2) or alternatively one of the HWMP proactive path selection methods with the Gate Announcement field equal to 1:

- The proactive PREQ mechanism (see 14.10.4.2), with the Gate Announcement field equal to 1 (see 14.10.9.3)
- The proactive RANN mechanism (see 14.10.4.3), with the Gate Announcement field equal to 1 (see 14.10.12.3)

When the mesh gate uses one of the HWMP proactive path selection methods, the gate announcement protocol is not used.

A mesh STA discovers the presence of a mesh gate with access to the external network by receiving GANN elements (or PREQ element and RANN element with the Gate Announcement field equal to 1 if using such mechanisms). Mesh STAs propagate these elements to neighbor mesh STAs in order to propagate the information throughout the MBSS.

NOTE—The decision to set dot11MeshGateAnnouncements to true is beyond the scope of the standard. In general, the mesh gate announces that it has access to a broader network beyond the MBSS, using gate announcement protocol or HWMP proactive path selection methods with the Gate Announcement field equal to 1. One example of this configuration is that the mesh gate has access to a portal through the DS.

When a mesh gate has access to IEEE 802 STAs outside the mesh BSS (a mesh STA collocated with an AP, another mesh STA that belongs to another MBSS, etc.), the mesh gate acts as an intermediary for the IEEE 802 STAs outside the MBSS so that the forwarding information inside the MBSS only contains addresses that belong to the MBSS. The mesh gate acting as an intermediary for external STAs is termed proxy mesh gate. When the end station of an IEEE 802 communication is an external STA, mesh STAs handle addresses of the end-to-end IEEE 802 communication as depicted in Figure 9-64. Proxy mesh gate operation is described in 14.11.4.

14.11.2 Gate announcement (GANN)

14.11.2.1 General

Subclause 14.11.2 describes the function, generation, and processing of the GANN element.

14.11.2.2 Function

The GANN element, described in 9.4.2.111, is used to announce the presence of a mesh gate with dot11MeshGateAnnouncements equal to true in the mesh BSS. Gate announcements allow mesh STAs to discover such a mesh gate and, if necessary, to build a path toward it.

14.11.2.3 Conditions for generating and sending a GANN element

A mesh STA shall send a GANN element in a Gate Announcement frame, as defined in 9.6.17.4, in the following cases:

Case A: Original transmission

The mesh STA is a mesh gate not sending PREQ element or RANN element with the Gate Announcement field equal to 1 and dot11MeshGateAnnouncements is true. The mesh STA shall transmit the Gate Announcement frame at every dot11MeshGateAnnouncementInterval.

The content of a GANN element in Case A shall be as shown in Table 14-27.

The mesh gate shall assign the GANN Sequence Number from a single modulo 2^{32} counter, starting at 0 and incrementing by 1 for each GANN element transmission.

Table 14-27—Contents of a GANN element in Case A

| Field | Value |
|----------------------|--|
| Element ID | Value given in Table 9-77 for the GANN element |
| Length | 15 |
| Flags | Reserved |
| Hop Count | 0 |
| Element TTL | Maximum number of hops allowed for the gate announcement |
| Mesh Gate Address | Mesh STA MAC address |
| GANN Sequence Number | Previous GANN sequence number + 1 |
| Interval | dot11MeshGateAnnouncementInterval |

Case B: Propagation

All of the following conditions are met:

- The mesh STA has received and accepted a gate announcement.
- The decremented Element TTL of the gate announcement is greater than or equal to 1.
- dot11MeshForwarding is true.

The content of a GANN element in Case B shall be as shown in Table 14-28.

Table 14-28—Contents of a GANN element in Case B

| Field | Value |
|----------------------|--|
| Element ID | Value given in Table 9-77 for the GANN element |
| Length | 15 |
| Flags | As received |
| Hop Count | As received + 1 |
| Element TTL | As received – 1 |
| Mesh Gate Address | As received |
| GANN Sequence Number | As received |
| Interval | As received |

14.11.2.4 GANN element processing

14.11.2.4.1 General

A received gate announcement is subject to certain acceptance criteria. Processing depends on the contents of the gate announcement and the information available at the receiving mesh STA.

14.11.2.4.2 Acceptance criteria

The GANN element shall not be accepted (and shall not be processed as described in 14.11.2.4.3) if the GANN Sequence Number of the gate announcement is equal or lower than the GANN Sequence Number of the most recently accepted gate announcement with the same Mesh Gate Address.

14.11.2.4.3 Effect of receipt

The following applies only to a GANN element that was accepted according to the acceptance criteria in 14.11.2.4.2. The receiving mesh STA shall transmit a gate announcement as described in 14.11.2.3, Case B.

The Mesh Gate Address field of the GANN contains the address of the mesh gate, and may be stored for the purpose of determining paths to the mesh gates. Paths to mesh gates allow mesh STAs to forward MSDUs to addresses for which no path could be determined (see 10.35.8).

14.11.3 Data forwarding at proxy mesh gates

14.11.3.1 General

Forwarding of MSDUs from the DS into the MBSS by a proxy mesh gate follows the procedures given in 10.35.2.

Forwarding of MSDUs from the MBSS into the DS by a proxy mesh gate follows the procedures that apply for the specific collocated network.

A proxy mesh gate learns the addresses of the other proxy mesh gates in the MBSS and of external addresses proxied by them through the receipt of path selection messages and messages carrying proxy information (for example, see 9.4.2.116).

14.11.3.2 Forwarding of MSDUs from the MBSS to the DS

On receipt of an individually addressed mesh Data frame from the MBSS with Address Extension Mode equal to “Address5&6” (see Table 9-20), a proxy mesh gate shall perform the following:

- If Address 5 is a known destination MAC address in the proxy information (external address) and proxied by the proxy mesh gate, the proxy mesh gate forwards the MSDU to the external address through the DS.
- If Address 5 is a known destination MAC address in the proxy information (external address) and proxied by a different proxy mesh gate, the MSDU is forwarded through the MBSS to the proxy mesh gate that proxies the external address. The MSDU is sent into the MBSS according to the procedures in 10.35.3.1 as an individually addressed mesh Data frame with Address 3 set to the MAC address of the proxy mesh gate of the proxy information proxying Address 5, Address 4 set to the MAC address of this proxy mesh gate, and Address 5 and Address 6 kept unchanged.
- If Address 5 is unknown to the proxy mesh gate, the mesh gate forwards the MSDU to the DS. The mesh gate may send an error notification to the mesh source of the MSDU. In HWMP, this is done by sending a PERR element as described in 14.10.11.3 Case C.

On receipt of group addressed mesh Data frame from the MBSS with Address Extension Mode equal to “Address4” (see Table 9-20), a proxy mesh gate shall forward the MSDU to the DS using a group addressed frame.

14.11.3.3 Forwarding of MSDUs from the DS to the MBSS

On receipt of an individually addressed MSDU from the DS, a proxy mesh gate shall perform the following depending on the possible destination:

- a) If the destination of the MSDU is a mesh STA address that the mesh gate knows to be inside the MBSS, the mesh gate forwards the MSDU according to the procedures for frame addressing and data forwarding at source mesh STAs in an MBSS (10.35.3.1). The MSDU shall be transmitted using a frame with the four-address MAC header format (with the Address Extension Mode subfield in the Mesh Control field set to “Address5&6” (see Table 9-20)), where the Mesh Address Extension subfield in the Mesh Control field carries the addresses of the end stations, as specified in row “Mesh Data (proxied, individually addressed)” of Table 9-42. The address fields are set as follows:
 - Address 1: The address of the next-hop mesh STA (toward the destination mesh STA according to the forwarding information—see 10.35.2)
 - Address 2: The address of the proxy mesh gate
 - Address 3: The address of the destination mesh STA
 - Address 4: The address of the proxy mesh gate
 - Address 5: The address of the destination end mesh STA that is the same as Address 3
 - Address 6: The address of the source end mesh STA that is the source address of the MSDU received from the DS
- b) If the destination of the MSDU is an external address that is proxied by another proxy mesh gate in the MBSS, the mesh gate forwards the MSDU according to the procedures for frame addressing and data forwarding at source mesh STAs in an MBSS (10.35.3.1). The MSDU shall be transmitted using a frame with the four-address MAC header format [with the Address Extension Mode subfield in the Mesh Control field set to “Address5&6” (see Table 9-20)], where the Mesh Address Extension subfield in the Mesh Control field carries the addresses of the end stations, as specified in row “Mesh Data (proxied, individually addressed)” of Table 9-42. The address fields are set as follows:
 - Address 1: The address of the next-hop mesh STA (toward the proxy mesh gate of the destination of the MSDU as derived from the proxy information (see 14.11.4.2) and according to the forwarding information—10.35.2)
 - Address 2: The address of this proxy mesh gate
 - Address 3: The address of the proxy mesh gate of the destination of the MSDU as derived from the proxy information (see 14.11.4.2)
 - Address 4: The address of this proxy mesh gate
 - Address 5: The address of the destination end mesh STA that is the destination address of the MSDU received from the DS
 - Address 6: The address of the source end mesh STA that is the source address of the MSDU received from the DS
- c) If the MSDU has a destination address that is unknown to the mesh gate, the mesh gate forwards the MSDU to other known mesh gates in the MBSS as an individually addressed frame according to the procedures for frame addressing and data forwarding of individually addressed frames at source mesh STAs in an MBSS (10.35.3.1). The MSDU shall be transmitted using a frame with the four-address MAC header format [with the Address Extension Mode subfield in the Mesh Control field set to “Address5&6” (see Table 9-20)], where the Mesh Address Extension subfield in the Mesh Control field carries the addresses of the end stations, as specified in row “Mesh Data (proxied, individually addressed)” of Table 9-42. The address fields are set as follows:
 - Address 1: The address of the next-hop mesh STA (toward the other known mesh gate in the MBSS according to the forwarding information—see 10.35.2)
 - Address 2: The address of this proxy mesh gate
 - Address 3: The address of the other known mesh gate in the MBSS
 - Address 4: The address of this proxy mesh gate

- Address 5: The address of the destination end mesh STA that is the unknown destination address of the MSDU received from the DS
- Address 6: The address of the source end mesh STA that is the source address of the MSDU received from the DS

Note that the procedure to determine that an address is unknown depends on the active path selection protocol. It might require an attempt to establish a path to the destination (see 14.8).

On receipt of a group addressed MSDU from the DS, the mesh gate forwards the MSDU according to the procedures for frame addressing and data forwarding of group addressed frames at source mesh STAs in an MBSS (10.35.4.1). The MSDU shall be transmitted using a frame with the three-address MAC header format [with the Address Extension Mode subfield in the Mesh Control field set to “Address4” (see Table 9-20)], where the Mesh Address Extension subfield in the Mesh Control field carries the address of the source end stations, as specified in row “Mesh Data (proxied, group addressed)” of Table 9-42. The address fields are set as follows:

- Address 1: The group address
- Address 2: The address of the proxy mesh gate
- Address 3: The address of the proxy mesh gate
- Address 4: The address of the source external STA

14.11.4 Proxy information and proxy update

14.11.4.1 General

Forwarding information of mesh STAs only contains addresses of mesh STAs that belong to the MBSS. However, the end station of the IEEE 802 communication may be an IEEE 802 station outside the MBSS, and such station is called *external STA*. Examples of external STAs are as follows:

- STAs that are associated with an AP that is collocated with a mesh STA
- STAs that are behind a mesh gate

Mesh STAs forward MSDUs to external STAs by treating MAC addresses of the external STAs as external addresses. The mesh STAs that are the destination mesh STAs of the messages destined to external STAs are called *proxy mesh gates*, and their MAC addresses are called *proxy addresses*.

NOTE—External STAs are reached using mesh services solely, i.e., they are not part of an MBSS. The mechanism by which the proxy mesh gate bridges the MBSS and the external STAs is beyond the scope of the standard. However, the standard describes the method by which mesh STAs use the external addresses that are discovered and bridged by the proxy mesh gate.

14.11.4.2 Proxy information

Proxy mesh gates and source mesh STAs of MSDUs destined to external STAs maintain proxy information. Proxy information contains the external address, the corresponding proxy address, the sequence number of the proxy information, and the corresponding proxy information lifetime.

Mesh STAs can learn the addresses of proxy mesh gates and of the external stations proxied by these proxy mesh gates through the receipt of proxy update messages or path selection messages carrying proxy information. Particularly, proxy information is updated in the following circumstances:

- A mesh STA receives and processes a proxy update (see 14.11.4.3)
- A mesh STA receives and processes an element of the active path selection protocol containing proxy information. In HWMP, these are PREQ elements (see 14.10.9.4.3), PREP elements (see 14.10.10.4.3), and PERR elements (see 14.10.11.4.3)

Additionally, proxy mesh gates may also proactively maintain proxy information on external STAs.

When the proxy information lifetime is specified, a mesh STA shall maintain the proxy information as valid information until the lifetime expires. Details of the lifetime are described in 14.11.4.3.4.

The sequence number of the proxy information and the proxy mesh gate address define a chronological order of the proxy information of an external STA at a specific proxy mesh gate.

When the proxy information is created at the proxy mesh gate, the proxy sequence number is initialized to an arbitrary value. The proxy information sequence number in the proxy information at the proxy mesh gate is incremented by 1 before the transmission of the proxy information to another mesh station. The proxy information sequence number shall be incremented if the proxy information is invalidated.

If proxy information is transmitted in HWMP elements (PREQ, PREP, and PERR), the proxy information sequence number is set to the HWMP SN of the HWMP element containing this proxy information.

Comparison of the proxy information sequence numbers is performed using a circular modulo 2^{32} comparison.

Valid proxy information is used to determine and set Address 5 and Address 6 in individually addressed mesh Data frames, or Address 4 in group addressed mesh Data frames.

14.11.4.3 Proxy update (PXU)

14.11.4.3.1 General

Subclause 14.11.4.3 describes the function, generation, and processing of the PXU element.

14.11.4.3.2 Function

A mesh STA generates a PXU element to inform a destination mesh STA about proxy information of external addresses that are reachable through the proxy mesh gate specified in the PXU element.

NOTE—Typically, a proxy mesh gate generates and sends a PXU element to another proxy mesh gate in the MBSS or a mesh STA that originates traffic to the external stations proxied by the proxy mesh gate. However, the standard also allows other usage of the PXU element.

The PXU element is transmitted in a Proxy Update frame (an individually addressed frame). The Proxy Update frame may contain multiple PXU elements when needed (for instance, the proxy mesh gate has a large number of proxy information).

14.11.4.3.3 Conditions for generating and sending a PXU element

A proxy mesh gate may transmit a PXU when it adds, updates, or deletes an external address to (or from) its proxy information. A proxy mesh gate may also transmit a PXU at periodic intervals.

A mesh STA that holds proxy information of a proxy mesh gate in the MBSS may also transmit a PXU.

A mesh STA may retransmit the same PXU element repeatedly until the mesh STA receives a PXUC element from the destination mesh STA. See 14.11.4.4.

The content of a PXU element shall be as shown in Table 14-29.

The proxy mesh gate shall assign the PXU ID from a single modulo 256 counter, starting at 0 and incrementing by 1 for each PXU element.

Table 14-29—Contents of a PXU element

| Field | | Value/description |
|---------------------------------|-----------------------------------|--|
| Element ID | | Value given in Table 9-77 for the PXU element |
| Length | | 8 + length of N Proxy Information fields |
| PXU ID | | Previous PXU ID + 1 |
| PXU Originator MAC Address | | MAC address of the originator of the PXU |
| Number of Proxy Information (N) | | Number of proxy information reported to the destination mesh STA ($N \geq 1$). |
| Per Proxy Information | Flags | Bit 0: 0: add proxy information; 1: delete proxy information Bit 1: 0: Proxy MAC Address field present; 1: Proxy MAC Address = PXU Originator MAC Address, Proxy MAC Address field not present Bit 2: 0: Proxy Information Lifetime field not present; 1: Proxy Information Lifetime field present. If Bit 0 is 1, Bit 1 shall be set to 0. Bit 3–7: Reserved |
| | External MAC Address | MAC address of the STA proxied by the proxy mesh gate. |
| | Proxy Information Sequence Number | Proxy information sequence number of the proxy information after being incremented. See 14.11.4.2. |
| | Proxy MAC Address | MAC address of the proxy mesh gate. This field is present if Bit 1 of the Flags field is 0; it is not present otherwise. |
| | Proxy Information Lifetime | The proxy information lifetime of this proxy information as taken from the proxy information of the originator of the PXU. |

14.11.4.3.4 Effect of receipt of a PXU element

A mesh STA that receives the PXU element shall update its proxy information with the list of proxy information reported in the PXU under the following conditions:

- Proxy information for the external MAC address and the proxy mesh gate reported in the Proxy Information field of the PXU does not exist at the mesh STA.
- Proxy information for the external MAC address and the proxy mesh gate reported in the Proxy Information field of the PXU does exist at the mesh STA and the value of the Proxy Information Sequence Number subfield in the received PXU is larger than the value of the proxy information sequence number in the proxy information at the mesh STA.

When multiple PXU elements are contained in the received Proxy Update frame, the recipient mesh STA shall process all of the PXU elements in the frame.

The MAC address of the proxy mesh gate is taken from the Proxy MAC Address subfield in the Proxy Information field when bit 1 in the Flags subfield is equal to 0, and from the PXU Originator MAC Address field in the PXU element when bit 1 in the Flags subfield is equal to 1.

The MAC address of the external STA is taken from the External MAC Address subfield of the corresponding Proxy Information field in the received PXU element.

The sequence number of the proxy information is taken from the Proxy Information Sequence Number subfield of the corresponding Proxy Information field in the received PXU element.

If the Proxy Information Lifetime subfield is present (the Lifetime subfield in the Flags subfield is 1) and there is already proxy information stored for the proxy mesh gate and external address reported in the proxy information of the PXU element, the mesh STA shall set the proxy lifetime to the larger one of the proxy lifetime reported by the PXU and the stored proxy information.

If the Proxy Information Lifetime subfield is present (bit 2 of the Flags subfield is 1) and there is proxy information stored for the proxy mesh gate and external address reported in the proxy information of the PXU element, the mesh STA shall set the proxy information lifetime to the value in the Proxy Information Lifetime subfield.

If the Proxy Information Lifetime subfield is not present, the lifetime of the proxy information is the same as the lifetime of the path to the proxy address. Alternatively, the lifetime of the proxy information may be set to a value representing infinity.

The destination mesh STA that received the PXU shall send a PXUC element to the originator mesh STA of the PXU as described in 14.11.4.4.3.

14.11.4.4 Proxy update confirmation (PXUC)

14.11.4.4.1 General

Subclause 14.11.4.4 describes the function, generation, and processing of the PXUC element.

14.11.4.4.2 Function

A PXUC element is generated by the destination mesh STA of a PXU to inform the sender of the PXU that the PXU has been properly received.

The PXUC element is transmitted in a Proxy Update Confirmation frame (an individually addressed frame). The Proxy Update Confirmation frame may contain multiple PXUC elements in order to confirm the reception of multiple PXU elements to the destination of the Proxy Update Confirmation frame.

14.11.4.4.3 Conditions for generating and sending a PXUC element

The destination mesh STA of a Proxy Update frame containing a PXU element shall send a PXUC element to the originator mesh STA of the PXU element.

The content of a PXUC element shall be as shown in Table 14-30.

Table 14-30—Contents of a PXUC element

| Field | Value/description |
|------------------------------|--|
| Element ID | Value given in Table 9-77 for the PXUC element |
| Length | 7 |
| PXU ID | PXU ID of the PXU that is being confirmed |
| Destination mesh STA Address | MAC address of the originator of the PXUC |

14.11.4.4.4 Effect of receipt of PXUC element

If a mesh STA receives a PXUC element in a PXUC frame in response to a PXU element it originated, the mesh STA shall no longer send any PXUs with the same PXU ID as given in the received PXUC element.

14.11.5 Mesh STA collocation

A mesh STA collocated with another STA shall use a MAC address that is different from the one used by the collocated STA. This precludes ambiguities relating to the presence of the Mesh Control field in the Frame Body (see 9.2.4.7), GTK use (see 12.6.1.1.10), and proxy information (see 14.11.4.2).

Path selection with collocated mesh STAs using HWMP is described in 14.10.5.

14.12 Intra-mesh congestion control

14.12.1 General

Intra-mesh congestion control is based on the following three main mechanisms:

- a) Local congestion monitoring and congestion detection
- b) Congestion control signaling
- c) Local rate control

A mesh STA shall activate a congestion control protocol specified by dot11MeshActiveCongestionControlMode. At any given time, there is only one congestion control protocol active in a particular MBSS, signaled in the Congestion Control Mode Identifier field of the Mesh Configuration element. This standard specifies the congestion control signaling protocol that shall be available in any MBSS with an activated congestion control.

NOTE—This standard allows for inclusion of more advanced or alternative congestion control schemes through the Congestion Control Mode Identifier in the Mesh Configuration element.

14.12.2 Congestion control signaling protocol

When dot11MeshActiveCongestionControlMode is congestionControlSignaling (1), the mesh STA activates the congestion control signaling protocol. The congestion control signaling protocol specifies the signaling messages used with intra-mesh congestion control. Specific algorithms for local congestion monitoring and congestion detection are beyond the scope of the congestion control signaling protocol.

The congestion control signaling protocol is triggered after congestion is detected at a mesh STA. A mesh STA that detects congestion, and the traffic destination causing this congestion, may transmit a Congestion Control Notification frame to the mesh STAs of the traffic source and other neighboring mesh STAs. The frame contains one or more Congestion Notification elements, each of which specifies the traffic destination causing the congestion and the expected duration of the congestion per AC per mesh destination as estimated by the congested mesh STA.

Upon receipt of a Congestion Notification frame a mesh STA may stop forwarding, or reduce the rate of forwarding, traffic to the destinations listed in the Congestion Notification elements via the mesh STA reporting congestion for the duration specified in the Congestion Notification element. It may also send its own Congestion Control Notification frame to mesh STAs that are the source of the reported congestion, and other neighboring mesh STAs. Any time difference between receipt of the original Congestion Control Notification frame and the transmission of this new Congestion Control Notification frame should be reflected in the duration indicated in the new congestion control notification in such a way that any timers

set by mesh STAs in response to the first report of congestion for a given destination all expire at the same time.

If the Destination MAC Address field in a received Congestion Notification element is the group address, it should be interpreted to mean that communication with the transmitter of this frame should be stopped, or reduced, for the duration specified in the Congestion Notification element. This event should not result in the transmission of a Congestion Notification element with a Destination MAC Address field set to the group address to any neighbor mesh STAs.

When the duration of a traffic congestion report has expired, a mesh STA should resume forwarding traffic to the destinations that were listed in the traffic congestion report via the mesh STA that reported congestion.

NOTE 1—Local policies/mechanisms implemented in a mesh STA might be required to achieve timely transmission of the congestion control signaling messages and to avoid transmission of stale messages that might reduce network efficiency.

NOTE 2—A mesh STA that receives a Congestion Control Notification frame might choose to adjust its frame rate, defined by the number of transmitted frames per a unit of time, to the sender of the Congestion Control Notification frame in the identified congested AC(s) for the duration specified in the Congestion Notification element. The reduction of the frame rate to a congested mesh STA avoids waste of the mesh resources for transmission of packets that with high probability will not be handled/forwarded by the congested mesh STA.

14.13 Synchronization and beaconing in MBSSs

14.13.1 TSF for MBSSs

A mesh STA shall initialize and update its TSF timer according to the MBSS's active synchronization method. Each mesh STA shall maintain a TSF timer as described in 11.1.3.1, and comply with the TSF timer accuracy as described in 11.1.3.9.

14.13.2 Extensible synchronization framework

14.13.2.1 General

This standard introduces an extensible framework to enable the implementation of multiple synchronization methods for mesh STAs. Within the extensible synchronization framework, the neighbor offset synchronization method is defined as the default mandatory synchronization method in order to enable minimal synchronization capabilities and interoperability between mesh STAs that use MCCA, MBCA, or operate in light or deep sleep mode. The framework allows the integration of other synchronization methods into MBSSs. A vendor may implement any synchronization method using this framework to meet special application needs. Although a mesh STA may include multiple implementations of synchronization methods, only one synchronization method at a time shall be used by a mesh STA. All mesh STAs in an MBSS use the same synchronization method; see 14.2.7 item a). The MBSS's active synchronization method is controlled by the SME and given to the MLME by dot11MeshActiveSynchronizationMethod.

A mesh STA shall announce the MBSS's active synchronization method using the Synchronization Method Identifier field in the Mesh Configuration element in their Beacon and Probe Response frames.

14.13.2.2 Neighbor offset synchronization method

14.13.2.2.1 General

When dot11MeshActiveSynchronizationMethod is neighborOffsetSynchronization (1), the mesh STA shall use the neighbor offset synchronization method as its active synchronization method, and maintain the timing offset value between its own TSF timer and the TSF timer of each neighbor STA with which it

synchronizes. The mesh STA shall set the Synchronization Method Identifier field in the Mesh Configuration element to 1.

The mesh STA shall maintain synchronization with all of its neighbor peer mesh STAs up to dot11MeshNbrOffsetMaxNeighbor mesh STAs. The mesh STA should maintain synchronization with additional neighbor mesh STAs that are in the same MBSS up to a total of dot11MeshNbrOffsetMaxNeighbor mesh STAs and also, additional neighbor mesh STAs that are outside of the MBSS up to a total of dot11MeshNbrOffsetMaxNeighbor mesh STAs.

Upon receipt of an MLME-MESHNEIGHBOROFFSETSETSYNCSTART.request primitive, the MLME shall start synchronization using the neighbor offset synchronization method with the specified peer STA. Upon receipt of an MLME-MESHNEIGHBOROFFSETSETSYNCSTOP.request primitive, the MLME shall stop synchronization using the neighbor offset synchronization method with the specified peer STA.

A mesh STA that utilizes the neighbor offset synchronization method may start its TSF timer independently of other mesh STAs. The mesh STA shall calculate the timing offset value with respect to the neighbor STA with which it maintains synchronization, as described in 14.13.2.2.2. The mesh STA shall adjust its TSF timer based on time stamps received in Beacon or Probe Response frames from neighbor STAs with which it maintains synchronization, as described in 14.13.2.2.3.

When the mesh STA alternates awake state and doze state, it might not always listen to the Beacon frames of a neighbor mesh STA with which it maintains synchronization. However, it shall comply with the clock drift compensation procedures and TSF jitter allowance as described in 14.13.2.2.3. See S.3.6 for more guidelines.

14.13.2.2.2 Timing offset calculation

When dot11MeshActiveSynchronizationMethod is neighborOffsetSynchronization (1), the mesh STA shall calculate the timing offset value with respect to the neighbor STA with which it maintains synchronization. The calculation of the timing offset value is based on time stamps from the received Beacon and Probe Response frames as follows:

$$T_{\text{offset}} = T_t - T_r$$

where

T_{offset} is the timing offset value

T_t is the value in the Timestamp field in the received frame

T_r is the frame reception time measured in the TSF timer of the mesh STA

The offset value is represented as a signed integer. The unit of the offset value is μs . The mesh STA shall keep the T_{offset} value calculated from the latest Beacon or Probe Response frame received from each neighbor STA with which it maintains synchronization.

A mesh STA may translate the time measured in the TSF of the neighbor STA into the time base of its own TSF as follows:

$$T_{\text{self}} = T_{\text{neighbor}} - T_{\text{offset}}$$

where

T_{self} is the translated time in its own TSF

T_{neighbor} is the time measured in the TSF timer of the neighbor STA

Upon receipt of an MLME-MESHNEIGHBOROFFSETCALCULATE.request primitive, the MLME shall receive a Beacon or Probe Response frame from the specified neighbor STA, calculate the T_{offset} from the received frame, and report the calculated T_{offset} to the SME by responding with an MLME-MESHNEIGHBOROFFSETCALCULATE.confirm primitive. T_{offset} is used to provide the timing reference of neighbor STAs.

14.13.2.2.3 Clock drift adjustment

When dot11MeshActiveSynchronizationMethod is neighborOffsetSynchronization (1), the mesh STA shall examine the reception time of the Beacon frames from neighbor STAs with which it maintains synchronization and adjust its TSF timer to compensate the relative timing error among neighbor mesh STAs caused by the clock drift. The mesh STA adjusts its TSF so that its TSF counting is aligned to the most delayed neighbor STA.

When the mesh STA receives a Beacon frame or a Probe Response frame from one of the neighbor STAs with which it maintains synchronization, the mesh STA shall perform the following measurement procedure:

- The mesh STA checks if the transmitter of the Beacon frame or Probe Response frame is in the process of the TBTT adjustment (see 14.13.4.4.3). If the received frame contains the Mesh Configuration element and the TBTT Adjusting subfield in the Mesh Configuration field is 1, the mesh STA shall invalidate the T_{offset} value for this neighbor STA and shall not perform the following steps.
- The mesh STA checks if it has a valid T_{offset} value obtained from the previous Beacon or Probe Response frame reception from the transmitter of the received frame. If it does not have the valid T_{offset} value, it shall not perform the following steps.
- The mesh STA calculates the clock drift amount $T_{ClockDrift}$ by comparing the $T_{offset,p}$, the offset value obtained previously for this neighbor STA, and the $T_{offset,c}$, the offset value obtained from the current frame reception.

$$T_{ClockDrift} = T_{offset,p} - T_{offset,c}$$

where

$T_{ClockDrift}$ is the clock drift amount in μs represented as a signed integer.

- The mesh STA shall compare the $T_{ClockDrift}$ value with the $T_{MaxClockDrift}$, the largest $T_{ClockDrift}$ value obtained from other neighbor STA within this beacon period. If the $T_{ClockDrift}$ value for this neighbor STA is greater than the $T_{MaxClockDrift}$ value, the mesh STA replaces the $T_{MaxClockDrift}$ value with the $T_{ClockDrift}$ value, in order to determine the largest $T_{ClockDrift}$ value among neighbor STAs.

When the previous $T_{ClockDrift}$ values have been stable for a neighbor mesh STA, the mesh STA may substitute the previous $T_{ClockDrift}$ value for the $T_{ClockDrift}$ value in the measurement procedure and process the step d), at the time of a TBTT of the neighbor STA, without receiving a Beacon frame.

Before the mesh STA transmits a Beacon frame, it shall perform the following adjustment procedure:

- The mesh STA checks if the current $T_{MaxClockDrift}$ value is greater than zero. If the $T_{MaxClockDrift}$ value is greater than zero, it shall continue the following steps. Otherwise, it shall initialize the $T_{MaxClockDrift}$ with zero and shall not perform the following step.
- If the $T_{MaxClockDrift}$ value is smaller than 0.04% of its beacon interval, the mesh STA shall adjust its TSF timer so that the next TBTT will be delayed for the duration of the $T_{MaxClockDrift}$ and initialize the $T_{MaxClockDrift}$ value with zero. Otherwise, it shall adjust its TSF timer so that the next TBTT will be delayed for the duration of 0.04% of its beacon interval and subtract the value of 0.04% of its beacon interval from the $T_{MaxClockDrift}$.

The mesh STA may adjust its TSF timer only to slow the counting. The mesh STA may adjust its TSF timer within the range of 0.04% in a beacon period.

When the delay amount at each beacon period is not stable, the mesh STA should frequently listen to neighbor STAs' Beacon frames. An implementation might reduce TSF timer jitter caused by the adjustment procedure by making additional adjustments to the $T_{MaxClockDrift}$, as long as the mesh STA's TSF count is aligned to the most delayed neighbor mesh STA. The means of making these additional adjustments is beyond the scope of this standard.

NOTE—This clock drift compensation procedure does not intend to maintain a strict synchronization. It aims to stop TBTT drifting away among neighbor mesh STAs, allowing some jitter of TSF timer.

14.13.3 Beaconing

14.13.3.1 Beacon generation in MBSSs

A mesh STA transmits Beacon frames that are specific to an MBSS. Beacon frames for MBSS, infrastructure BSS, or IBSS are differentiated by the Capability Information field in the Beacon frame as specified in 9.4.1.4. A mesh STA that collocates with an AP generates Beacon frames for the MBSS independently of the AP.

The mesh STA shall define a series of TBTTs exactly dot11BeaconPeriod TUs apart. Time zero is defined to be a TBTT with the Beacon frame containing a DTIM. At each TBTT, the mesh STA shall schedule a Beacon frame as the next frame for transmission according to the medium access rules specified in Clause 10.

NOTE—To achieve this requirement, the mesh STA suspends any pending transmissions until the beacon has been transmitted. In the case of a DTIM, the mesh STA also suspends any pending individually addressed transmissions until any pending group addressed transmissions have been performed (see 14.14.5).

The beacon period is included in Beacon and Probe Response frames.

The mesh STA shall start beacons upon the receipt of the MLME-START.request primitive.

14.13.3.2 Beacon reception for mesh STA

A mesh STA shall use information from the Timestamp field without regard to the BSSID or Mesh ID in order to obtain information necessary for synchronization, if the mesh STA maintains synchronization with the transmitter of the Beacon frame. A mesh STA may use information from the Beacon Interval field and the Beacon Timing element without regard for the Mesh ID in order to obtain information necessary for MBCA, if the mesh STA maintains synchronization with the transmitter of the Beacon frame and dot11MBCAActivated is true. A mesh STA may use information from the MCCAOP Advertisement Overview element and MCCAOP Advertisement element without regard for the Mesh ID in order to obtain information necessary for MCCA, if the mesh STA maintains synchronization with the transmitter of the Beacon frame and dot11MCCAActivated is true.

A mesh STA in a mesh BSS shall use information that is not in the CF Parameter Set element, the Timestamp field, the Beacon Interval field, the Beacon Timing element, the MCCAOP Advertisement Overview element, or the MCCAOP Advertisement element in received Beacon frames only if the mesh STA maintains a mesh peering with the transmitter of the Beacon frame.

14.13.4 Mesh beacon collision avoidance (MBCA)

14.13.4.1 Overview

Mesh STAs use the mesh beacon collision avoidance (MBCA) protocol to detect and mitigate collisions among Beacon frames transmitted by other STAs (including mesh STAs, IBSS APs, and IBSS STAs) on the same channel within the range of 2 hops. MBCA mitigates hidden node problems with respect to Beacon frames.

NOTE—Beacon frames are transmitted without acknowledgment and might collide with other frames. In a mesh BSS, multiple STAs transmit Beacon frames periodically, and mesh STAs might be located out of range of each other. This implies that Beacon frames might suffer from the so-called hidden node problem and might not be received by neighbor STAs. Once Beacon frames from hidden STAs start to collide, Beacon frames keep on colliding if these hidden STAs transmit Beacon frames at the same beacon interval that is a typical operation. MBCA provides a set of rules to mitigate this problem.

When `dot11MBCAActivated` is true, the mesh STA shall set the MBCA Enabled subfield in the Mesh Capability field of the Mesh Configuration element to 1.

MBCA is composed of beacon timing advertisements, TBTT selection, and TBTT adjustment. When `dot11MBCAActivated` is true, the mesh STA advertises the TBTT and beacon interval of its neighbor STAs through the Beacon Timing element as described in 14.13.4.2. Upon reception of the Beacon Timing element, the mesh STA obtains the beacon timing information of its neighbor mesh STAs and uses this information for its TBTT selection and TBTT adjustment as described in 14.13.4.3 and 14.13.4.4. The mesh STA may also perform additional procedures described in 14.13.4.5 and 14.13.4.6.

When `dot11MBCAActivated` is true, the mesh STA that alternates awake state and doze state should listen to Beacon frames from its neighbor STAs, with which it maintains synchronization, often, in order to advertise and obtain the recent TBTT information.

14.13.4.2 Beacon timing advertisement

14.13.4.2.1 General

When `dot11MBCAActivated` is true, the mesh STA shall contain Beacon Timing element in Beacon and Probe Response frames in order to advertise its beacon timing information. The mesh STA calculates the TBTT of its neighbor STAs with which it maintains synchronization as described in 14.13.4.2.2, and composes beacon timing information as described in 14.13.4.2.3. The mesh STA collects the beacon timing information from each neighbor STA with which it maintains synchronization. The collection of the beacon timing information is termed “beacon timing information set.” The mesh STA contains whole or part of the beacon timing information set in the Beacon Timing element as described in 14.13.4.2.5. The mesh STA also maintains the status number of the beacon timing information set and contains the status number in the Beacon Timing element as described in 14.13.4.2.4. The receiver of the Beacon Timing element uses the received beacon timing information as described in 14.13.4.2.6.

14.13.4.2.2 Calculation of neighbor STA’s TBTT

When a Beacon frame is received from one of its neighbor STAs with which the mesh STA maintains synchronization, the mesh STA shall calculate the TBTT of the received Beacon frame as follows:

$$T_{TBTT} = T_r - (T_t \bmod (T_{BeaconInterval} \times 1024))$$

where

- T_{TBTT} is the calculated TBTT
- T_r is the frame reception time measured in the TSF timer of the receiving mesh STA
- T_t is the value in the Timestamp field in the received frame
- $T_{BeaconInterval}$ is the value in the Beacon Interval field in the received frame

The T_{TBTT} is used as described in 14.13.4.2.3.

Further, the mesh STA shall calculate the time difference between the TBTT of the received Beacon frame and the time predicted from the past TBTT as follows:

$$T_{Delta} = | T_{TBTT,c} - (T_{TBTT,p} + (T_{BeaconInterval} \times N_{Count})) |$$

where

| | |
|----------------------|---|
| T_{Delta} | is the time difference |
| $T_{TBTT,c}$ | is the TBTT calculated from the received Beacon frame |
| $T_{TBTT,p}$ | is the TBTT calculated for the first time after the latest status number update (see 14.13.4.2.4) |
| $T_{BeaconInterval}$ | is the value in the Beacon Interval field in the received Beacon frame |
| N_{Count} | is the number of TBTTs since $T_{TBTT,p}$ has been calculated |

T_{Delta} is used to maintain the status number described in 14.13.4.2.4.

14.13.4.2.3 Beacon timing information

The mesh STA shall keep the latest T_{TBTT} together with the beacon interval contained in the received frame and the identifier of the neighbor STA as the beacon timing information with respect to the neighbor STA. When the elapsed time since the latest Beacon frame reception is smaller than 524 288 TU, the beacon timing information is valid.

NOTE—The beacon timing information provides the time reference for a series of the TBTTs of the corresponding STA. Using the beacon timing information, a mesh STA is able to predict future TBTTs by adding the reported beacon interval to the reported TBTT.

The mesh STA shall collect the valid beacon timing information from each neighbor STA with which it maintains synchronization and keep the collection as the beacon timing information set. The beacon timing information set is advertised to its neighbor mesh STAs through the Beacon Timing element as described in 14.13.4.2.5.

When the amount of neighbors, for which valid beacon timing information is kept, is large, the beacon timing information set may be divided into multiple tuples of beacon timing information. In such case, a tuple of beacon timing information is included in the Beacon Timing element (see 14.13.4.2.5).

14.13.4.2.4 Maintenance of the status number

The mesh STA shall maintain the status number of the beacon timing information set. The status number is set to a value from a single modulo 16 counter, starting at 0 and incrementing by 1 for each transmission of a frame containing the Beacon Timing element after the mesh STA encountered any of the following events:

- a) It starts or stops maintaining synchronization with a neighbor STA.
- b) It receives a Beacon frame from a neighbor STA with which it maintains synchronization and the calculated T_{Delta} (see 14.13.4.2.2) is larger than 255 μ s.
- c) It completes the TBTT adjustment procedure described in 14.13.4.4.3.

The mesh STA shall set the Status Number subfield in the Report Control field in the Beacon Timing element to the status number. The Status Number subfield in the Report Control field facilitates the detection of the changes in the beacon timing information set.

14.13.4.2.5 Transmitter's procedure

When dot11MBCAActivated is true, the mesh STA shall report the TBTT and beacon interval of its neighbor STAs through the Beacon Timing element as described in this subclause.

The Beacon Timing element reports on timing information of the Beacon frames that are received from the neighbor STAs with which the mesh STA maintains synchronization on the operating channel. The mesh

STA shall include the Beacon Timing element in Probe Response frames and in TBTT Adjustment Request frames. The mesh STA shall also include the Beacon Timing element in Beacon frames as specified by dot11MeshBeaconTimingReportInterval and dot11MeshBeaconTimingReportMaxNum. The Beacon Timing element is present in a Beacon frame when the DTIM Count value in the Beacon frame is zero or equal to an integer multiple of dot11MeshBeaconTimingReportInterval.

The maximum number of Beacon Timing Information fields contained in a Beacon Timing element is limited to dot11MeshBeaconTimingReportMaxNum for Beacon frames, or is limited by the maximum element size for other frames. When the number of neighbors, for which valid beacon timing information is kept, is equal or smaller than the limit, the mesh STA shall include all the beacon timing information in a single Beacon Timing element, setting both Beacon Timing Element Number and More Beacon Timing Elements subfield in the Report Control field to 0. When the number of neighbors, for which valid beacon timing information is kept, exceeds the limit, the mesh STA shall divide the beacon timing information set into multiple tuples and assign each tuple with an index number starting from 0. When the beacon timing information set is divided, the mesh STA shall include the successive tuples of beacon timing information in the Beacon Timing elements. In this case, the mesh STA shall set the Beacon Timing Element Number subfield in the Report Control field to the index number of the tuple. The mesh STA shall set the More Beacon Timing Elements subfield in the Report Control field to 1 when it has one or more beacon timing information tuples with a larger index number. The mesh STA shall divide the beacon timing information set into no more than N_{info} tuples, where

$$N_{info} = \lceil N_v / N_{max} \rceil,$$

N_v is the number of valid beacon timing information fields

N_{max} is the maximum number of Beacon Timing Information fields in the Beacon Timing element

The mesh STA may update the combination of the tuples only when the status number described in 14.13.4.2.4 is updated. The mesh STA shall include newly updated beacon timing information (i.e., beacon timing information that causes an update of the status number as described in 14.13.4.2.4) in the tuple with a smaller index number. When the status number is updated, the mesh STA shall include the tuple of beacon timing information indexed as 0 in the Beacon Timing element in the subsequent Beacon frame. Successive tuples shall be transmitted in ascending order of the index number in the successive Beacon frames.

NOTE—The standard does not impose mesh STAs to advertise a fragmented beacon timing information set sequentially in its Beacon frames at all times. This implies that the mesh STA might advertise tuples with a smaller index number more frequently, which is useful to notify new beacon timing information efficiently.

When the mesh STA receives a Probe Request frame containing a Beacon Timing element ID in its Request element, it shall respond with a Probe Response frame containing the Beacon Timing element. If all beacon timing information cannot be contained in a Beacon Timing element, the mesh STA shall include multiple Beacon Timing elements containing successive tuples of beacon timing information in the order of the Request element (see Table 9-34) so that all tuples are transmitted.

14.13.4.2.6 Receiver's procedure

A mesh STA with dot11MBCAActivated equal to true that receives a Beacon Timing element obtains the beacon timing information of its neighbor mesh STA and uses it for its TBTT selection and TBTT adjustment as described in 14.13.4.3 and 14.13.4.4.

When a mesh STA receives a Beacon frame with a Beacon Timing element that contains only a subset of the beacon timing information set, the mesh STA may transmit a Probe Request frame containing a Beacon Timing element ID in its Request element to the transmitter of the Beacon Timing element, in order to request the rest of the beacon timing information.

NOTE 1—The Report Control field in the Beacon Timing element facilitates the detection of the missing beacon timing information.

NOTE 2—Once the entire beacon timing information set with a particular Status Number is obtained, the mesh STA does not need to retrieve beacon timing information as long as the Status Number remains the same.

A mesh STA that receives the Beacon Timing element shall record the reported TBTT and its successive TBTTs as neighbor's essential beacon reception timing if the MSB of the Neighbor STA ID field in the corresponding Beacon Timing Information field is 0. The essential beacon reception timing is used to control the transmission of frames as described in 14.13.4.5.

A mesh STA can also check if its neighbor mesh STAs received its Beacon frame successfully by checking whether the Beacon Timing elements received from its neighbor mesh STAs contain beacon timing information of the mesh STA. When the Beacon Timing element is received from one of the peer mesh STAs, the mesh STA checks if the MSB of the Neighbor STA ID subfield is set to 0 and the rest of the field matches with the 7 LSBs of the AID value assigned to the mesh STA through the mesh peering establishment. When the Beacon Timing element is received from a nonpeer mesh STA, the mesh STA checks if the MSB of the Neighbor STA ID subfield is set to 1 and the rest of the field matches with the 7 LSBs of its own MAC address (taking the I/G bit as the MSB). If the matching is verified, the corresponding beacon timing information represents the correct beacon reception by the neighbor mesh STA.

If a Beacon frame is received from a neighbor peer mesh STA that is either in active mode or in light sleep mode, the Beacon Timing element is present in the frame, and all beacon timing information is contained in the Beacon Timing element, the mesh STA shall verify whether the neighbor peer mesh STA received its Beacon frame. If the Beacon Timing element does not contain beacon timing information of the mesh STA or the Neighbor TBTT subfield of the corresponding beacon timing information does not reflect the recent TBTT of the mesh STA, the mesh STA considers the previous Beacon frame was not received by the neighbor peer mesh STA.

14.13.4.3 TBTT selection

When dot11MBCAActivated is true, the mesh STA performs the TBTT selection described herein before it starts beacons (see 14.2.8). The mesh STA selects its TBTTs and its beacon interval so that its Beacon frames do not collide with Beacon frames transmitted by other STAs in its 2 hop range.

Before the mesh STA starts beacons, it performs scanning and discovered neighbor STAs are reported through an MLME-SCAN.confirm primitive (see 14.2.6). Using TimeStamp, Local Time, and Beacon Period in the BSSDescriptionSet parameter provided by the MLME-SCAN.confirm primitive, the mesh STA shall obtain the TBTT and beacon interval of its neighbor STAs operating on the same channel as the mesh STA starts to operate. The mesh STA shall also collect the beacon timing information contained in the Beacon Timing elements received on the channel through Beacon Timing in the BSSDescriptionSet parameter provided by the MLME-SCAN.confirm primitive, in order to obtain the TBTT and beacon interval of STAs in 2 hop range. After obtaining this information, the mesh STA shall look for a timing of its beacon transmissions so that its Beacon frames are likely not to collide with Beacon frames transmitted by other STAs in its 2 hop range. The mesh STA shall update its TSF timer and select its beacon interval to set its TBTTs to the appropriate timing, and then it shall start beacons using the MLME-START.request primitive.

14.13.4.4 TBTT adjustment

14.13.4.4.1 Self-determined TBTT adjustment

When dot11MBCAActivated is true, the mesh STA checks if it does not transmit Beacon frames during the beacon transmissions of other STAs within its 2 hop range using the Beacon Timing element received from its neighbor peer mesh STA.

When the mesh STA discovers that its Beacon frames repeatedly collide with the Beacon frames of a neighbor or a neighbor's neighbor and its TBTT comes later than the TBTT of the colliding STA at the time of collision, it shall perform the TBTT scanning procedure described in 14.13.4.4.3. If the mesh STA finds an alternative TBTT, it shall start the TBTT adjustment procedure as described in 14.13.4.4.3.

14.13.4.4.2 Requested TBTT adjustment

When a mesh STA discovers that Beacon frames from two or more neighbor STAs are colliding repeatedly or a series of TBTTs are close enough to trigger frequent beacon collisions, the mesh STA may transmit a TBTT Adjustment Request frame to the neighbor mesh STA of which the TBTT comes last at a particular collision timing in order to request this neighbor mesh STA to adjust its TBTT. The TBTT Adjustment Request frame may be transmitted only if the following conditions hold:

- The recipient of the TBTT Adjustment Request frame is a peer mesh STA and has set the MBCA Enabled subfield in the Mesh Capability field of the Mesh Configuration element to 1.
- The other colliding STA does not include the Mesh Configuration element in its Beacon frames or the TBTT Adjusting field in the Mesh Configuration element is 0.

When dot11MBCAAActivated is true, the mesh STA that receives a TBTT Adjustment Request frame shall perform the TBTT scanning procedure described in 14.13.4.4.3, and determine if it can find an appropriate alternative timing for its TBTTs. After the completion of the TBTT scanning procedure, the mesh STA that receives the TBTT Adjustment Request frame shall respond with a TBTT Adjustment Response frame containing the result of the TBTT scanning in the Status Code field. If the mesh STA finds an alternative TBTT, it shall agree with the request. If it agrees with the request, the Status Code field is set to SUCCESS in the TBTT Adjustment Response frame, and it shall complete the TBTT adjustment procedure described in 14.13.4.4.3. If it does not agree with the request, it shall indicate the reason in the Status Code field in the TBTT Adjustment Response frame. A mesh STA may set the Status Code to either SUCCESS, REFUSED_REASON_UNSPECIFIED, or CANNOT_FIND_ALTERNATIVE_TBTT in the TBTT Adjustment Response frame.

14.13.4.4.3 TBTT scanning and adjustment procedures

When a mesh STA is in need of TBTT adjustment, it tries to find an alternative TBTT first. The mesh STA shall perform the TBTT scanning procedure as follows:

- The mesh STA checks if its beacon timing information and collected neighbor's beacon timing information are sufficiently new. If the mesh STA did not receive a Beacon frame from a neighbor STA with which it maintains synchronization at the latest TBTT, it shall receive a Beacon or Probe Response frame from the neighbor STA and obtain the TBTT of the neighbor STA and the beacon timing information contained in the Beacon Timing element.

NOTE—This is particularly important if the mesh STA is in deep sleep mode for a neighbor peer mesh STA.
- Using the latest TBTT of its neighbor STAs and the latest beacon timing information of neighbor mesh STAs, the mesh STA shall look for an alternative TBTT that does not cause beacon collision among the STAs in its 2 hop range.

If an alternative TBTT is not available, the mesh STA terminates the procedure. If an alternative TBTT is available, the mesh STA shall start the TBTT adjustment procedure as follows:

- The mesh STA shall set the TBTT Adjusting field in the Mesh Configuration element to 1 in order to announce that the TBTT adjustment procedure is ongoing.
- The mesh STA shall suspend its TSF timer for a period of time, no longer than half of the Group Delivery Idle Time (defined in 14.14.5) within a single beacon period, to slow its TSF.
- The mesh STA shall adjust TBTT information of the neighbor STAs (see 14.13.4.2.3), that are to be contained in the Beacon Timing element, accordingly by subtracting the delay amount.

- When dot11MCCAActivated is true, the mesh STA shall adjust the MCCAOP reservations accordingly by modifying the MCCAOP Offset of each MCCAOP reservation. See 10.23.3.3.
- The mesh STA shall repeat suspending its TSF timer over multiple beacon periods until its TBTT is set to the alternative TBTT.
- Upon completion of the TBTT adjustment, the mesh STA shall update the status number as described in 14.13.4.2.4 and shall set the TBTT Adjusting field in the Mesh Configuration element to 0.

NOTE—A mesh STA in deep sleep mode might interpret its neighbor mesh STA’s TBTT adjustment as a large TSF jitter. When a mesh STA in deep sleep mode observes a large TSF jitter and the Status Number in the Report Control field in the Beacon Timing element of the received Beacon frame (or Probe Response frame) has been updated, the mesh STA in deep sleep mode should not take this jitter as clock drift and listen to the next Beacon frame to verify if the clock drift is large.

14.13.4.5 Frame transmission across reported TBTT

When dot11MBCAActivated is true, the mesh STA should not extend its transmissions across TBTT of its neighbor STAs with which it maintains synchronization. Further, the mesh STA should not extend its transmissions, other than Beacon frames, across all essential beacon reception timing (see 14.13.4.2.6) reported from its neighbor mesh STAs with which it maintains synchronization. This operation helps in reducing the hidden STA interference with beacon reception at its neighbor mesh STAs. When both dot11MBCAActivated and dot11MCCAActivated are true, the mesh STA shall not extend its transmissions across TBTT of its neighbor STAs with which it maintains synchronization. Further, the mesh STA shall not extend its transmissions, other than Beacon frames, across all beacon reception timing reported from its neighbor mesh STAs with which it maintains synchronization.

After silencing for dot11MeshAverageBeaconFrameDuration μ s from the reported neighbor’s TBTT, the mesh STA may start transmitting frames again.

14.13.4.6 Delayed beacon transmissions

A mesh STA may occasionally delay its Beacon frame transmission from its TBTT for a pseudorandom time. This attribute is specified by dot11MeshDelayedBeaconTxInterval, dot11MeshDelayedBeaconTxMinDelay, and dot11MeshDelayedBeaconTxMaxDelay. When dot11MeshDelayedBeaconTxInterval is set to nonzero value, the mesh STA shall delay its Beacon frame transmission from TBTT, once every dot11MeshDelayedBeaconTxInterval. When the mesh STA transmits a Beacon frame with delay from its TBTT, the delay time shall be randomly selected between dot11MeshDelayedBeaconTxMinDelay and dot11MeshDelayedBeaconTxMaxDelay μ s.

NOTE—Delayed beacon transmission allows mesh STAs to discover Beacon frames that are transmitted from multiple mesh STAs with TBTTs close to each other. It is recommended to set dot11MeshDelayedBeaconTxMaxDelay to a time longer than the typical duration of Beacon frames.

14.14 Power save in a mesh BSS

14.14.1 General

A mesh STA may use mesh power management modes to reduce its power consumption. A mesh STA manages each of its mesh peerings with a peer-specific mesh power management mode as described in 14.14.2.2. A mesh STA may set the mesh power management mode for a mesh peering independently of the mesh power management modes for its other mesh peerings. A mesh STA also manages a nonpeer mesh power management mode as described in 14.14.2.3. When a mesh STA is in light sleep mode or in deep sleep mode for a mesh peering, the mesh STA shall maintain its mesh awake window as described in 14.14.6.

A mesh STA shall have the capability to buffer frames and to perform mesh power management mode tracking for the peer-specific mesh power management modes of its peer mesh STAs, as described in 14.14.7. A mesh STA shall use mesh peer service periods for individually addressed frame transmissions to neighbor peer mesh STAs that are either in light sleep mode or in deep sleep mode toward this mesh STA, as described in 14.14.9. A mesh STA transmits group addressed frames after the Beacon frame containing DTIM when any of its peer mesh STAs is in light sleep mode or deep sleep mode for the mesh peering with the mesh STA (see 14.14.4 and 14.14.5). These capabilities are referred to as *support for power save*.

14.14.2 Mesh power management modes

14.14.2.1 General

The manner in which a mesh STA transitions between power states is determined by its peer-specific mesh power management modes and its nonpeer mesh power management mode. A mesh STA shall be in awake state if any of the conditions specified in 14.14.8.6 is not fulfilled. A mesh STA maintains peer-specific mesh power management modes for each of its mesh peerings as described in 14.14.2.2. A mesh STA may have a different peer-specific mesh power management mode for each mesh peering. A mesh STA maintains a nonpeer mesh power management mode for nonpeer mesh STAs that is described in 14.14.2.3. An example illustration of the use of peer specific and nonpeer mesh power management modes is shown in Figure 14-5.

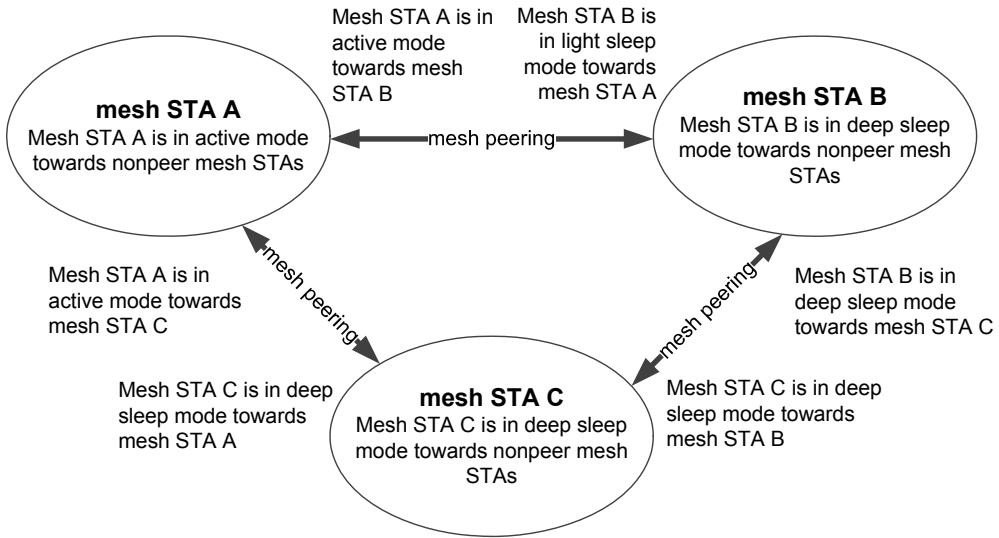

Figure 14-5—Example of mesh power management mode usage

14.14.2.2 Peer-specific mesh power management modes

The peer-specific mesh power management mode specifies the activity level of the mesh STA for the corresponding mesh peering. Three mesh power management modes are defined: active mode, light sleep mode, and deep sleep mode. The peer-specific mesh power management modes are defined as follows:

- *Active mode*: The mesh STA shall be in awake state all the time.
- *Light sleep mode*: The mesh STA alternates between awake state and doze state, as specified in 14.14.8.4. The mesh STA shall listen to all of the Beacon frames from the corresponding peer mesh STA.

- *Deep sleep mode*: The mesh STA alternates between awake state and doze state, as specified in 14.14.8.5. The mesh STA may choose not to listen to the Beacon frames from the corresponding peer mesh STA.

The combination of the Power Management subfield in the Frame Control field and the Mesh Power Save Level subfield in the QoS Control field contained in mesh Data frames indicates the peer-specific mesh power management mode as shown in the Table 14-31.

Table 14-31—Peer-specific mesh power management mode definition

| Activity level | Peer-specific mesh power management mode | Power Management subfield | Mesh Power Save Level subfield |
|--|--|---------------------------|--------------------------------|
| Highest  Lowest | Active mode | 0 | Reserved |
| | Light sleep mode | 1 | 0 |
| | Deep sleep mode | 1 | 1 |

14.14.2.3 Nonpeer mesh power management modes

The nonpeer mesh power management mode indicates the mesh power management mode of the mesh STA toward the nonpeer mesh STAs. Two nonpeer mesh power management modes are defined: active mode and deep sleep mode. The nonpeer mesh power management mode is indicated by the Power Management subfield in the Frame Control field in group addressed frames, Management frames transmitted to nonpeer neighbor STAs, and in Probe Response frames. When the Power Management subfield in the Frame Control field is set to 1, the nonpeer mesh power management mode is deep sleep mode. When the Power Management subfield in the Frame Control field is set to 0, the nonpeer mesh power management mode is active mode.

A mesh STA may send Probe Request and Mesh Peering Open Request frames to a nonpeer mesh STA that sets its nonpeer mesh power management mode to deep sleep mode only during the mesh awake window of the mesh STA.

14.14.3 Mesh power management mode indications and transitions

14.14.3.1 General

When a mesh STA is in active mode for a mesh peering, it shall set the Power Management subfield in the Frame Control field to 0 in all individually addressed Mesh Data or QoS Null frames transmitted to the corresponding peer mesh STA.

When a mesh STA is in light sleep mode for a mesh peering, it shall set the Power Management subfield in the Frame Control field to 1 and the Mesh Power Save Level subfield in the QoS Control field to 0 in all individually addressed Mesh Data or QoS Null frames transmitted to the corresponding peer mesh STA.

When a mesh STA is in deep sleep mode for a mesh peering, it shall set the Power Management subfield in the Frame Control field to 1 and the Mesh Power Save Level subfield in the QoS Control field to 1 in all individually addressed Mesh Data or QoS Null frames transmitted to the corresponding mesh STA.

When a mesh STA is in deep sleep mode for any of its mesh peerings, the Mesh Power Save Level subfield in the QoS Control field in group addressed mesh Data frames and the Mesh Power Save Level subfield in the Mesh Capability field in the Mesh Configuration element shall be set to 1. When a mesh STA is not in deep sleep mode for any of its mesh peerings, these subfields shall be set to 0.

To change peer-specific mesh power management modes, a mesh STA shall inform its peer mesh STAs through a successful frame exchange initiated by the mesh STA. The Power Management subfield in the Frame Control field and the Mesh Power Save Level subfield in the QoS Control field of the frame sent by the mesh STA in this exchange indicates the peer-specific mesh power management mode that the STA shall adopt upon successful completion of the entire frame exchange.

The algorithm to trigger the change of a peer-specific mesh power management mode is beyond the scope of this standard.

The nonpeer mesh power management mode is determined by the peer-specific mesh power management modes of the mesh STA. When a mesh STA is in light sleep mode or deep sleep mode for at least one mesh peering, it shall set the nonpeer mesh power management mode to deep sleep mode.

When a mesh STA is in active mode for nonpeer STAs, it shall set the Power Management subfield in the Frame Control field to 0 in group addressed frames, in Management frames transmitted to nonpeer mesh STAs, and in Probe Response frames.

When a mesh STA is in deep sleep mode for nonpeer STAs, it shall set the Power Management subfield in the Frame Control field to 1 in group addressed frames, in Management frames transmitted to nonpeer mesh STAs, and in Probe Response frames.

14.14.3.2 Transition to a higher activity level

A mesh STA may use group addressed or individually addressed Mesh Data or QoS Null frames to change its mesh power management mode to a higher activity level, for example; from deep sleep to light sleep or to active mode; or from light sleep to active mode.

Individually addressed frames may be used to temporarily raise the activity level of the mesh STA for a mesh peering.

NOTE—This is useful in cases when a link temporarily requires efficient data transmission with the peer mesh STA and the mesh STA is attempting to transit back to lower activity level without performing the mesh power management mode transition signaling with all peer mesh STAs.

14.14.3.3 Transition to a lower activity level

A mesh STA shall use acknowledged individually addressed Mesh Data or QoS Null frames to change its peer-specific mesh power management mode to a lower activity level, for example; from active mode to light or deep sleep mode; or from light sleep to deep sleep mode.

14.14.4 TIM transmissions in an MBSS

The TIM element identifies the peer mesh STAs for which traffic is pending and buffered in the reporting mesh STA. This information is coded in a partial virtual bitmap, as described in 9.4.2.6. In addition, the TIM contains an indication whether group addressed traffic is pending. Every neighbor peer mesh STA is assigned an AID by the reporting mesh STA as part of the mesh peering establishment process (see 14.3.1). The mesh STA shall identify those peer mesh STAs for which it is prepared to deliver⁴⁷ buffered MSDUs and MMPDUs by setting bits in the TIM’s partial virtual bitmap that correspond to the appropriate AIDs.

⁴⁷How the AP or mesh STA determines the traffic is prepared to deliver is outside the scope of this standard.

14.14.5 TIM types

There are two different TIM types: TIM and DTIM. A mesh STA shall transmit a TIM with every Beacon frame. Every DTIMPeriod, a TIM of type DTIM is transmitted with a Beacon frame. After transmitting a Beacon frame containing a DTIM, the mesh STA shall send the buffered group addressed MSDUs and MMPDUs, before transmitting any individually addressed frames. The More Data subfield of each group addressed frame shall be set to indicate the presence of further buffered group addressed MSDUs and MMPDUs. The mesh STA sets the More Data subfield to 0 in the last transmitted group addressed frame following the transmission of the DTIM Beacon frame.

While waiting to receive a group addressed frame that was previously indicated in a TIM element or More Data subfield, a mesh STA that detects CCA is IDLE for the duration of the PHY specific Group Delivery Idle Time may assume that no more frames destined to group addresses will be transmitted and may return to doze state. The Group Delivery Idle Time is identical to the TXOP limit for AC_VI specified by the default EDCA Parameter Set shown in Table 9-137.

14.14.6 Mesh awake window

A mesh STA shall be in awake state when its mesh awake window is active. A mesh awake window is active after the Beacon and Probe Response frames containing the Mesh Awake Window element. A mesh STA shall include the Mesh Awake Window element in its DTIM Beacon frames and may include the Mesh Awake Window element in its TIM Beacon and Probe Response frames. A mesh STA that operates in light sleep mode or deep sleep mode for any of its mesh peerings shall include the Mesh Awake Window element in its Beacon frame if the Beacon frame indicates buffered traffic for at least one peer mesh STA. The start of the mesh awake window is measured from the end of the Beacon or Probe Response frame transmission. The duration of the mesh awake window period is specified by dot11MeshAwakeWindowDuration. A mesh STA shall set the Mesh Awake Window field in the Mesh Awake Window element to dot11MeshAwakeWindowDuration. If the Mesh Awake Window element is not contained in the Beacon frame of a mesh STA, the duration of the mesh awake window period following this beacon is zero.

If the mesh STA that has its mesh awake window active transmits frames destined to group addresses, the duration of the mesh awake window is extended by an additional PostAwakeDuration. The PostAwakeDuration follows the group address frame, and the mesh STA that has its mesh awake window active shall stay in awake state until it has transmitted all of its group addressed frames and the PostAwakeDuration has expired. The PostAwakeDuration is equal to duration of the mesh awake window.

A mesh STA may send a frame to a peer mesh STA that is in light sleep mode or deep sleep mode for the corresponding mesh peering during the mesh awake window of this peer mesh STA. When a peer trigger frame is successfully transmitted it initiates a mesh peer service period as described in 14.14.9.

A mesh STA may send Class 1 or Class 2 frames, such as Probe Request or Mesh Peering Open frames, to a nonpeer mesh STA that is in deep sleep mode for nonpeer mesh STAs during the mesh awake window of this nonpeer mesh STA.

14.14.7 Power save support

As described in 14.14.2, a mesh STA indicates its peer-specific mesh power management modes and performs mesh power management mode tracking of the peer-specific mesh power management modes of its peer mesh STAs. A mesh STA shall not arbitrarily transmit frames to mesh STAs operating in a light or deep sleep mode, but shall buffer frames and only transmit them at designated times.

A mesh STA may transmit frames to a mesh STA operating in a light or deep sleep mode if the recipient mesh STA is in the awake state as defined in 14.14.8.4, 14.14.8.5, and 14.14.9; otherwise, the mesh STA shall not transmit frames and shall buffer frames.

As described in 14.14.4, a mesh STA indicates the presence of buffered traffic in TIM elements for all peer mesh STAs that operate in light or deep sleep mode toward the mesh STA. The mesh STA sets the bit for AID 0 (zero) in the Bitmap Control field of the TIM element to 1 when group addressed traffic is buffered, according to 9.4.2.6. As described in 14.14.5, a mesh STA transmits its group addressed frames after its DTIM beacon if any of its peer mesh STA is in light or deep sleep mode toward the mesh STA.

As described in 14.14.9, mesh peer service periods are used for frame transmissions toward a mesh STA that operates in light or deep sleep mode. Mesh peer service periods are not used in frame exchanges toward active mode mesh STAs.

A mesh STA may initiate a mesh peer service period with a peer mesh STA in deep or light sleep mode by transmitting a peer trigger frame when the mesh awake window of the peer mesh STA is active.

14.14.8 Operation in peer-specific and nonpeer mesh power management modes

14.14.8.1 General

Detailed operations of mesh STA in each mesh power management mode are described in the following subclauses. Figure 14-6 depicts example power state transitions of mesh STAs, when three mesh STAs are in the mesh power management modes shown in the Figure 14-5.

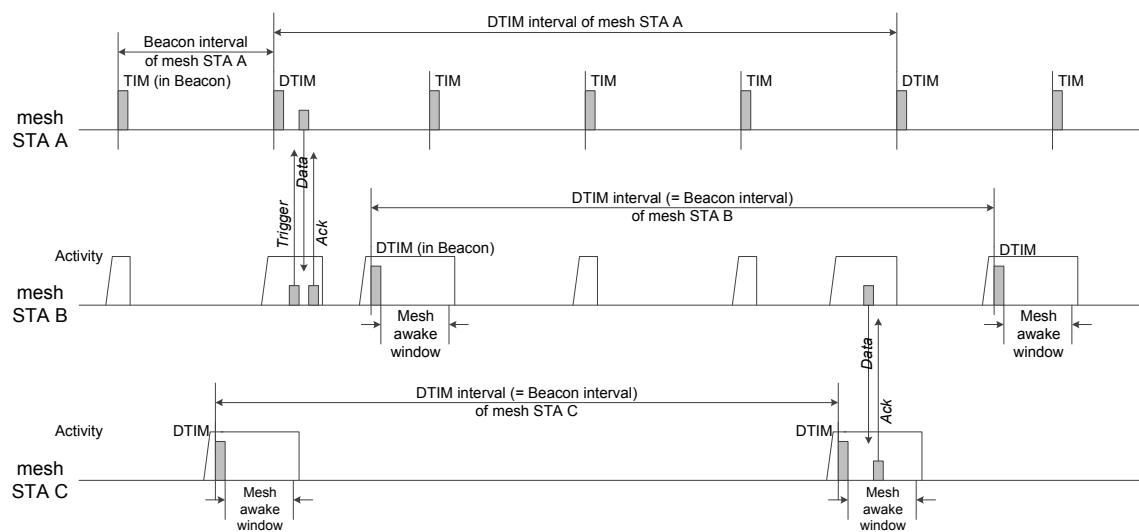

Figure 14-6—Mesh power management operation

14.14.8.2 Operation in active mode

When a mesh STA is in active mode for a mesh peering or for nonpeer mesh STAs, it shall be in awake state. Mesh peer service periods are not used in frame exchanges toward mesh STAs that are in active mode.

An active mode mesh STA may receive peer trigger frames from a peer mesh STA in light or deep sleep mode when there is no mesh peer service period ongoing between the peer mesh STAs.

14.14.8.3 Operation in deep sleep mode for nonpeer mesh STAs

If a mesh STA is in deep sleep mode for nonpeer mesh STAs, it shall enter the awake state prior to every TBTT of its own and shall remain in awake state after the beacon transmission for the duration of the mesh

awake window and the duration of its group addressed frame transmissions. The mesh STA may receive frames during its mesh awake window as described in 14.14.6.

When receiving a frame initiating a mesh peering management procedure, an authentication procedure, or a passive scanning procedure, a mesh STA in deep sleep mode for nonpeer mesh STAs shall operate in awake state at least until the completion of the mesh peering management procedure (see 14.3 and 14.5), until the completion of the authentication procedure (see 14.3.1 and 14.3.3), or the transmission of the Probe Response frame.

If a mesh STA receives a peer trigger frame initiating a mesh peer service period from a peer mesh STA, the mesh STA shall remain in awake state until the mesh peer service period is terminated as defined in 14.14.9.4.

A mesh STA may return to doze state after its mesh awake window if no frame initiating a response transaction or a mesh peer service period is received during the mesh awake window.

14.14.8.4 Operation in light sleep mode for a mesh peering

If a mesh STA is in light sleep mode for a mesh peering, it shall enter the awake state prior to every TBTT of the corresponding peer mesh STA to receive the Beacon frame from the peer mesh STA. The mesh STA may return to the doze state after the beacon reception from this peer mesh STA, if the peer mesh STA did not indicate buffered individually addressed or group addressed frames. If an indication of buffered individually addressed frames is received, the light sleep mode mesh STA shall send a peer trigger frame with the RSPI field set to 1 to initiate a mesh peer service period with the mesh STA that transmitted the Beacon frame (see 14.14.9.2). If an indication of buffered group addressed frames is received, the light sleep mode mesh STA shall remain in awake state after the DTIM Beacon reception to receive group addressed frames. The mesh STA shall remain awake state until the More Data subfield of a received group addressed frame is set to 0 or if no group addressed frame is received within the PHY specific Group Delivery Idle Time. (See 14.14.5.)

NOTE—When a mesh STA is in light sleep mode for a mesh peering, it sets its nonpeer mesh power management mode to deep sleep mode. This implies that a mesh STA operating in light sleep mode for a mesh peering is required to comply with the rules described in 14.14.8.3.

14.14.8.5 Operation in deep sleep mode for a mesh peering

A mesh STA operating in deep sleep mode for a mesh peering might not receive Beacon frames from the corresponding peer mesh STA. The logic of how the mesh STA in deep sleep mode maintains synchronization among neighbors is beyond the scope of this standard. Guidance for the synchronization maintenance by the mesh STA in deep sleep mode is given in S.3.6.

NOTE—When a mesh STA is in deep sleep mode for a mesh peering, it sets its nonpeer mesh power management mode to deep sleep mode. This implies that a mesh STA operating in deep sleep mode for a mesh peering is required to comply with the rules described in 14.14.8.3.

14.14.8.6 Conditions for doze state

A mesh STA may enter doze state if all of the following conditions are fulfilled:

- The mesh STA operates in light sleep mode or deep sleep mode for all of its mesh peerings, as described in 14.14.8.4 or 14.14.8.5
- The mesh STA has no mesh peer service period ongoing, as described in 14.14.9
- The mesh STA has no pending transaction of mesh peering management, authentication, nor passive scanning (see 14.14.8.3)
- The mesh awake window indicated by the mesh STA has expired, as described in 14.14.6

- The mesh STA has terminated its group addressed frames delivery sequence after its DTIM Beacon frame, as described in 14.14.5

Guidance for using the power save in mesh BSS and default parameter values are given in S.3.

14.14.9 Mesh peer service periods

14.14.9.1 General

Mesh peer service periods are used for individually addressed frame exchanges between neighbor peer mesh STAs in which at least one of the mesh STAs is in light or deep sleep mode for the corresponding mesh peering. A mesh peer service period is a period of time during which one or more individually addressed frames are transmitted between two peer mesh STAs. Within a mesh peer service period, a mesh STA may obtain multiple TXOPs. A mesh peer service period is directional. One mesh STA is the owner of the mesh peer service period. It obtains TXOPs in order to transmit Data frames or Management frames to the recipient in the mesh peer service period. At the end of the frame transmissions, the owner of the mesh peer service period terminates the mesh peer service period. The other mesh STA operates as the recipient of the mesh peer service period and does not obtain TXOPs for transmitting Data frames or Management frames to the owner of the mesh peer service period. A mesh STA may have multiple mesh peer service periods concurrently toward multiple neighbor peer mesh STAs. At most, one mesh peer service period is set up in each direction with each peer mesh STA.

A mesh peer service period is initiated by a peer trigger frame. A peer trigger frame may initiate two mesh peer service periods. This enables both the transmitter and the receiver of the peer trigger frame to become the owner of a mesh peer service period. An example mesh peer service period between two mesh STAs in light or deep sleep mode is shown in Figure 14-7. The numbering on the left-hand-side describes the phase of the operation: 1 indicates the Initiation phase, 2 indicates the data transmission phase, and 3 indicates the termination phase of the mesh peer service period.

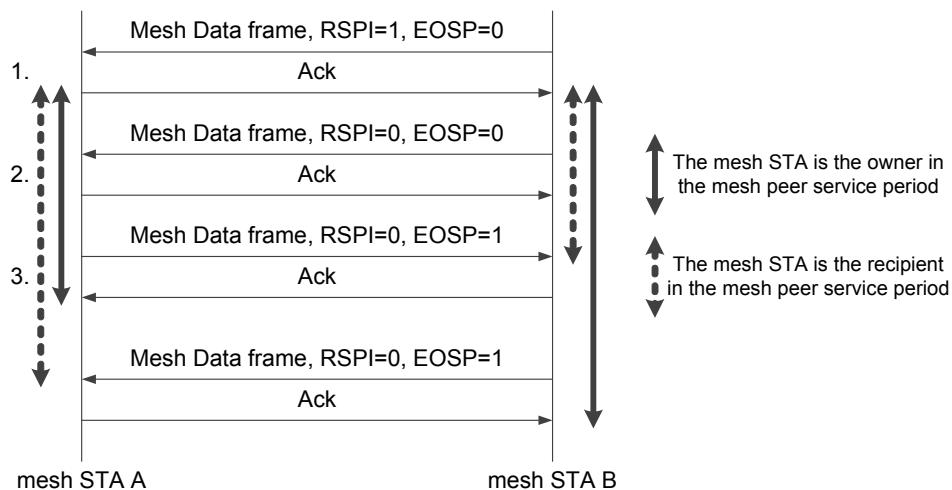

Figure 14-7—Mesh peer service period

14.14.9.2 Initiation of a mesh peer service period

A mesh Data frame or a QoS Null frame that requires acknowledgment are used as a peer trigger frame. The RSPI and the EOSP subfields in the QoS Control field control the initiation of a mesh peer service period.

Table 14-32 lists how mesh peer service periods shall be initiated with different combinations of RSPI and EOSP subfield values.

Table 14-32—Mesh peer service period triggering with RSPI and EOSP subfield combinations in peer trigger frame

| RSPI | EOSP | Mesh peer service period triggering |
|------|------|---|
| 0 | 0 | One mesh peer service period is initiated. The transmitter of the trigger frame is the owner in the mesh peer service period. |
| 0 | 1 | No mesh peer service period is initiated. |
| 1 | 0 | Two mesh peer service periods are initiated. Both mesh STAs are owners in a mesh peer service period. |
| 1 | 1 | One mesh peer service period is initiated. The receiver of the trigger frame is the owner in the mesh peer service period. |

Mesh peer service periods are not used in frame transmissions toward active mode mesh STAs.

The mesh peer service period may be initiated in the following cases:

- A mesh STA in light or deep sleep mode receives a peer trigger frame during its mesh awake window as described in 14.14.6
- A mesh STA in active mode receives a peer trigger frame from the peer mesh STA in light or deep sleep mode as described in 14.14.8.2
- A mesh STA receives a peer trigger frame from the peer mesh STA in light sleep mode as described in 14.14.8.4

In addition, when a mesh STA uses MCCA with a neighbor peer mesh STA while in a light sleep mode for the corresponding mesh peering, a scheduled service period begins at the each MCCAOP start time as described in 14.14.10. A mesh STA in a light or deep sleep mode shall enter the awake state prior to the start time of scheduled service period.

14.14.9.3 Operation during a mesh peer service period

During the mesh peer service period, the owner and the recipient of the mesh peer service period shall operate in awake state. The mesh peer service period may contain one or more TXOPs.

Reverse direction grant (RDG) shall not be used when the receiver of the TXOP operates in light or deep sleep mode for the link and there is no mesh peer service period ongoing toward the TXOP holder.

14.14.9.4 Termination of a mesh peer service period

The mesh peer service period is terminated after a successfully acknowledged QoS Null or mesh Data frame with the EOSP subfield set to 1 from the owner of the mesh peer service period.

If the mesh STA does not receive an acknowledgment to a frame that requires an acknowledgment and that is sent with the EOSP subfield set to 1, the mesh STA shall retransmit that frame at least once within the same mesh peer service period, subject to applicable retry or lifetime limits. The maximum number of retransmissions within the same mesh peer service period is the lesser of the Max Retry Limit and dot11MeshSTAMissingAckRetryLimit.

NOTE—If an acknowledgment to the retransmission of this last frame in the same mesh peer service period is not received, the mesh STA might use the next mesh peer service period to further retransmit that frame subject to the applicable retry or lifetime limit.

14.14.10 MCCA use by power saving mesh STA

When dot11MCCAActivated is true and the mesh STA establishes MCCAOPs, the mesh STA shall be in active mode or light sleep mode toward the neighbor peer mesh STAs with which it has established MCCAOPs.

A scheduled mesh peer service period begins at the MCCAOP start time, if the MCCAOP responder operates in light sleep mode for the MCCAOP owner. The MCCAOP owner is the owner of the scheduled mesh peer service period. The MCCAOP responder is the recipient of the scheduled mesh peer service period. Scheduled mesh peer service periods are not used if the MCCAOP responder is in active mode for the MCCAOP owner.

The scheduled mesh peer service period continues until it is successfully terminated by the acknowledged QoS Null or mesh Data frame with the EOSP subfield set to 1 from the owner of the mesh peer service period to the recipient of the mesh peer service period as described in 14.14.9.

15. DSSS PHY specification for the 2.4 GHz band designated for ISM applications

15.1 Overview

15.1.1 General

The PHY for the DSSS system is described in this clause. The RF LAN system is aimed for the 2.4 GHz band designated for ISM applications.

The DSSS system provides a WLAN with both a 1 Mb/s and a 2 Mb/s data payload communication capability. The DSSS system uses baseband modulations of differential binary phase shift keying (DBPSK) and differential quadrature phase shift keying (DQPSK) to provide the 1 Mb/s and 2 Mb/s data rates, respectively.

15.1.2 Scope

The PHY services provided to the IEEE 802.11 WLAN MAC by the 2.4 GHz DSSS system are described in this clause. The DSSS PHY consists of the following protocol functions:

- a) A function that defines a method of mapping the IEEE 802.11 MPDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs.
- b) A function that defines the characteristics of, and method of transmitting and receiving data through, a WM between two or more STAs each using the DSSS system.

15.1.3 DSSS PHY functions

15.1.3.1 General

The 2.4 GHz DSSS PHY architecture is depicted in the reference model shown in Figure 4-19 (in 4.9). The DSSS PHY contains two functional entities: the PHY function and the layer management function. Each of these functions is described in detail in the following subclauses.

The DSSS PHY service shall be provided to the MAC through the PHY service primitives described in Clause 8.

15.1.3.2 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME.

15.1.4 Service specification method and notation

The models represented by figures and state diagrams are intended to be illustrations of functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation, but do not necessarily reflect any particular implementation.

The service of a layer or sublayer is a set of capabilities that it offers to a user in the next-higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

15.2 DSSS PHY specific service parameter list

15.2.1 Introduction

The architecture of the IEEE 802.11 MAC is intended to be PHY independent. Some PHY implementations require medium management state machines running in the MAC sublayer in order to meet certain PHY requirements. These PHY-dependent MAC state machines reside in a sublayer defined as the MLME. In certain PHY implementations, the MLME may need to interact with the PLME as part of the normal PHY SAP primitives. These interactions are defined by the PLME parameter list currently defined in the PHY service primitives as TXVECTOR and RXVECTOR. The list of these parameters, and the values they may represent, are defined in the specific PHY specifications for each PHY. Subclause 15.2 addresses the TXVECTOR and RXVECTOR for the DSSS PHY.

15.2.2 TXVECTOR parameters

15.2.2.1 General

The parameters in Table 15-1 are defined as part of the TXVECTOR parameter list in the PHY-TXSTART.request primitive.

15.2.2.2 TXVECTOR LENGTH

The LENGTH parameter provided in the TXVECTOR is in octets and is converted to microseconds for inclusion in the PHY LENGTH field.

15.2.2.3 TXVECTOR DATARATE

The DATARATE parameter describes the bit rate at which the PHY shall transmit the PSDU. Its value takes any of the rates defined in Table 15-1.

Table 15-1—TXVECTOR parameters

| Parameter | Value |
|-----------------------------|--|
| LENGTH | 0 to $2^{12} - 1$ |
| DATARATE | 1, 2 Mb/s |
| SERVICE | Null |
| TXPWR_LEVEL_INDEX | 1 to 8 |
| TIME_OF_DEPARTURE_REQUESTED | false, true. When true, the MAC entity requests that the PHY entity measures and reports time of departure parameters corresponding to the time when the first frame energy is sent by the transmitting port; when false, the MAC entity requests that the PHY entity neither measures nor reports time of departure parameters. |
| TX_ANTENNA | 1 to 256 |

15.2.2.4 TXVECTOR SERVICE

The SERVICE parameter shall be null.

15.2.2.5 TXVECTOR TXPWR_LEVEL_INDEX

The allowed values for the TXPWR_LEVEL_INDEX parameter are in the range 1 to 8. This parameter is used to indicate which of the available TxPowerLevel attributes defined in the MIB shall be used for the current transmission.

15.2.2.6 TXVECTOR TIME_OF_DEPARTURE_REQUESTED

The allowed values are false or true. A parameter value of true indicates that the MAC sublayer is requesting that the PHY entity provides measurement of when the first frame energy is sent by the transmitting port and reporting within the PHY-TXSTART.confirm(TXSTATUS) primitive. A parameter value of false indicates that the MAC sublayer is requesting that the PHY entity not provide time of departure measurement nor reporting in the PHY-TXSTART.confirm(TXSTATUS) primitive.

15.2.2.7 TXVECTOR TX_ANTENNA

Selects the antenna used by the PHY for transmission (when diversity is disabled), in the range 1 to 256.

15.2.3 RXVECTOR parameters

15.2.3.1 General

The parameters listed in Table 15-2 are defined as part of the RXVECTOR parameter list in the PHY-RXSTART.indication primitive.

Table 15-2—RXVECTOR parameters

| Parameter | Value |
|---|--|
| LENGTH | 0 to $2^{12} - 1$ |
| RSSI | 0–255 |
| SIGNAL | 1, 2 Mb/s |
| SERVICE | 1, 2 Mb/s |
| RCPI (see NOTE) | 0–255 |
| SQ | 0–255 |
| RX_ANTENNA | 1–256 |
| RX_START_OF_FRAME_OFFSET | 0 to $2^{32} - 1$. An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the incoming frame arrived at the receive antenna connector to the point in time at which this primitive is issued to the MAC. |
| NOTE—Parameter is present only when dot11RadioMeasurementActivated is true. | |

15.2.3.2 RXVECTOR LENGTH

The MPDU length in octets (calculated from the LENGTH field in microseconds).

15.2.3.3 RXVECTOR RSSI

This parameter is a measure by the PHY of the energy observed at the antenna used to receive the current PPDU. RSSI shall be measured during the reception of the PHY preamble. RSSI is intended to be used in a relative manner, and it shall be a monotonically increasing function of the received power.

15.2.3.4 RXVECTOR SIGNAL

SIGNAL shall represent the data rate at which the current PPDU was received.

15.2.3.5 RXVECTOR SERVICE

The SERVICE parameter shall be null.

15.2.3.6 RXVECTOR RCPI

The allowed values for the RCPI parameter are in the range 0 to 255, as defined in 9.4.2.38. This parameter is a measure by the PHY of the received channel power. The performance requirements for the measurement of RCPI are defined in 15.4.6.6.

15.2.3.7 RXVECTOR SQ

SQ provides to the MAC entity the signal quality of the DSSS PHY PN code correlation. The SQ shall be sampled when the DSSS PHY achieves code lock and shall be held until the next code lock acquisition.

The SQ may be used in conjunction with RSSI as part of a CCA scheme.

15.2.3.8 RXVECTOR RX_ANTENNA

RX_ANTENNA reports the antenna used by the PHY for reception of the most recent packet.

15.2.4 TXSTATUS parameters

15.2.4.1 General

The parameters listed in Table 15-3 are defined as part of the TXSTATUS parameter list in the PHY-TXSTART.confirm primitive.

15.2.4.2 TXSTATUS TIME_OF_DEPARTURE

The allowed values for the TIME_OF_DEPARTURE parameter are integers in the range 0 to $2^{32}-1$. This parameter is used to indicate when the first frame energy is sent by the transmitting port in units equal to $1/\text{TIME_OF_DEPARTURE_ClockRate}$. TIME_OF_DEPARTURE may be included in the transmitted frame in order for recipients on multiple channels to determine the time differences of air propagation times between transmitter and recipients and hence to compute the location of the transmitter.

15.2.4.3 TXSTATUS TIME_OF_DEPARTURE_ClockRate

TIME_OF_DEPARTURE_ClockRate indicates the clock rate used for TIME_OF_DEPARTURE.

Table 15-3—TXSTATUS parameters

| Parameter | Value |
|-----------------------------|--|
| TIME_OF_DEPARTURE | 0 to $2^{32}-1$. The locally measured time when the first frame energy is sent by the transmitting port, in units equal to 1/ TIME_OF_DEPARTURE_ClockRate. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request. |
| TIME_OF_DEPARTURE_ClockRate | 0 to $2^{16}-1$. The clock rate, in units of MHz, is used to generate the TIME_OF_DEPARTURE value. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request. |
| TX_START_OF_FRAME_OFFSET | 0 to $2^{32}-1$. An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the frame was transmitted at the transmit antenna connector to the point in time at which this primitive is issued to the MAC. |

15.3 DSSS PHY

15.3.1 Overview

Subclause 15.3 provides a convergence procedure in which MPDUs are converted to and from PPDUs. During transmission, the MPDU shall be prepended with a PHY preamble and header to create the PPDU. At the receiver, the PHY preamble and header are processed to aid in demodulation and delivery of the MPDU.

15.3.2 PPDU format

Figure 15-1 shows the format for the PPDU including the DSSS PHY preamble, the DSSS PHY header, and the MPDU. The PHY preamble contains the following fields: SYNC and SFD. The PHY header contains the following fields: Signaling (SIGNAL), Service (SERVICE), length (LENGTH), and CRC-16 (CRC). Each of these fields is described in detail in 15.3.3.

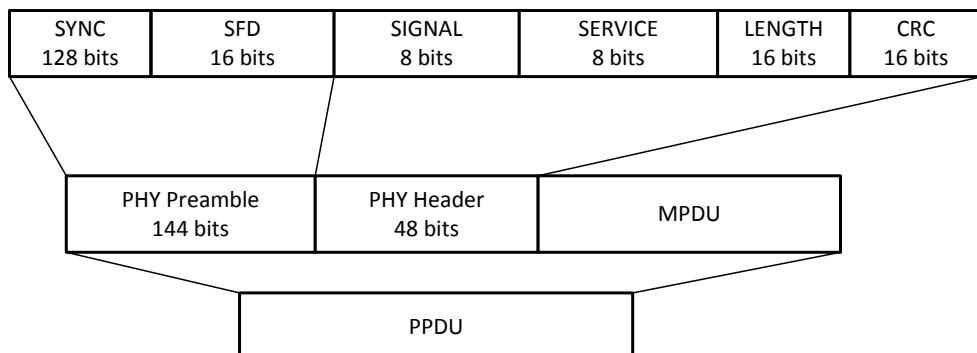

Figure 15-1—PPDU format

15.3.3 PHY field definitions

15.3.3.1 General

The entire PHY preamble and header shall be transmitted using the 1 Mb/s DBPSK modulation described in 15.4.5. All transmitted bits shall be scrambled using the feedthrough scrambler described in 15.3.4.

15.3.3.2 PHY SYNC field

The SYNC field shall consist of 128 bits of scrambled 1s. This field shall be provided so that the receiver can perform the necessary operations for synchronization.

15.3.3.3 PHY SFD

The SFD shall be provided to indicate the start of PHY-dependent parameters within the PHY preamble. The SFD shall be a 16-bit field, X'F3A0' (MSB to LSB). The LSB shall be transmitted first in time.

15.3.3.4 PHY SIGNAL field

The 8-bit SIGNAL field indicates to the PHY the modulation that shall be used for transmission (and reception) of the MPDU. The data rate shall be equal to the signal field value multiplied by 100 kb/s. The DSSS PHY currently supports two mandatory modulation services given by the following 8-bit words, where the LSB shall be transmitted first in time:

- a) X'0A' (MSB to LSB) for 1 Mb/s DBPSK
- b) X'14' (MSB to LSB) for 2 Mb/s DQPSK

The DSSS PHY rate change capability is described in 15.3.5. This field shall be protected by the CRC-16 FCS described in 15.3.3.7.

15.3.3.5 PHY SERVICE field

The 8-bit SERVICE field is reserved for future use; it shall be set to 0 on transmission and ignored on reception. The LSB shall be transmitted first in time. This field shall be protected by the CRC-16 FCS described in 15.3.3.7.

15.3.3.6 PHY LENGTH field

The PHY LENGTH field shall be an unsigned 16-bit integer that indicates the number of microseconds required to transmit the MPDU. The transmitted value shall be determined from the LENGTH parameter in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 8.3.5.5. The LENGTH field provided in the TXVECTOR is in octets and is converted to microseconds for inclusion in the PHY LENGTH field. The LSB shall be transmitted first in time. This field shall be protected by the CRC-16 FCS described in 15.3.3.7.

15.3.3.7 PHY CRC field

The SIGNAL, SERVICE, and LENGTH fields shall be protected with a CRC-16 FCS. The CRC-16 FCS shall be the 1s complement of the remainder generated by the modulo 2 division of the protected PHY fields by the polynomial:

$$x^{16} + x^{12} + x^5 + 1$$

The protected bits shall be processed in transmit order. All FCS calculations shall be made prior to data scrambling.

As an example, the SIGNAL, SERVICE, and LENGTH fields for a DBPSK signal with a packet length of 192 μ s (24 octets) would be given by the following:

0101 0000 0000 0000 0011 0000 0000 (leftmost bit transmitted first in time)

The 1s complement FCS for these protected PHY preamble bits would be the following:

0101 1011 0101 0111 (leftmost bit transmitted first in time)

Figure 15-2 depicts this example.

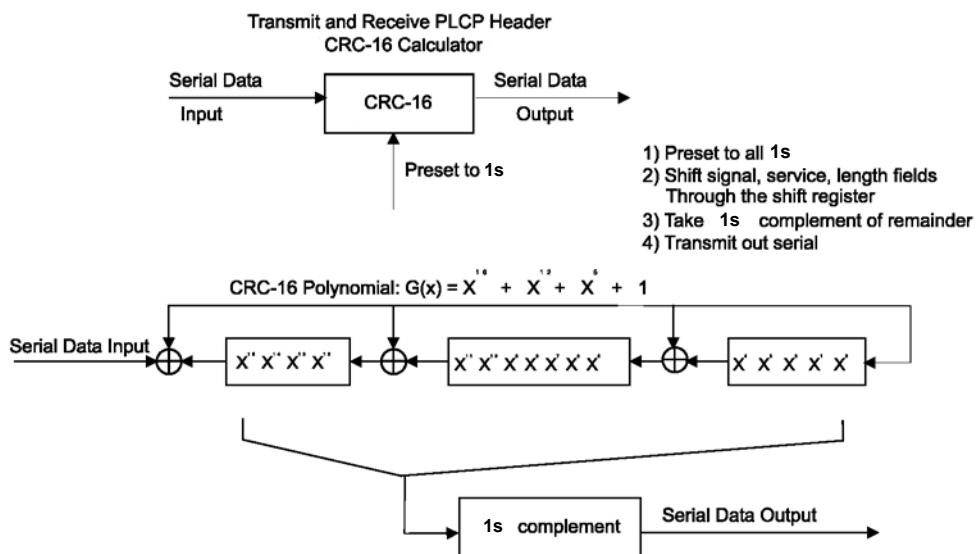

Figure 15-2—CRC-16 implementation

An illustrative example of the CRC-16 FCS using the information from Figure 15-2 follows in Figure 15-3.

| Data | CRC registers | |
|------|-------------------|--|
| | MSB | LSB |
| 0 | 1111111111111111 | ; initialize preset to 1s |
| 1 | 11011111011111 | |

| 0 | 1010010010101000 | |
| 0 | 0101101101010111 | ; 1s complement, result = CRC FCS parity |

Figure 15-3—Example CRC calculation

15.3.4 PHY/DSSS PHY data scrambler and descrambler

The polynomial $G(z) = z^{-7} + z^{-4} + 1$ shall be used to scramble all bits transmitted by the DSSS PHY. The feedthrough configuration of the scrambler and descrambler is self-synchronizing, which requires no prior knowledge of the transmitter initialization of the scrambler for receive processing. Figure 15-4 and Figure 15-5 show typical implementations of the data scrambler and descrambler, but other implementations are possible.

The scrambler should be initialized to any state except all 1s when transmitting.

Scrambler Polynomial; $G(z)=z^7 + z^4 + 1$

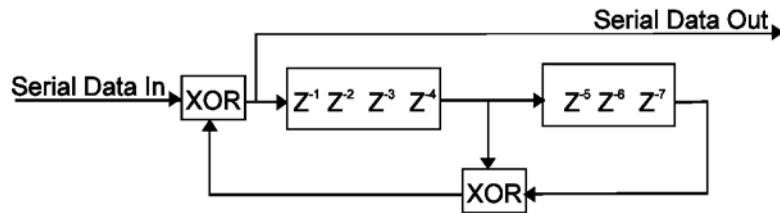

Figure 15-4—Data scrambler

Descrambler Polynomial; $G(z)=z^7 + z^4 + 1$

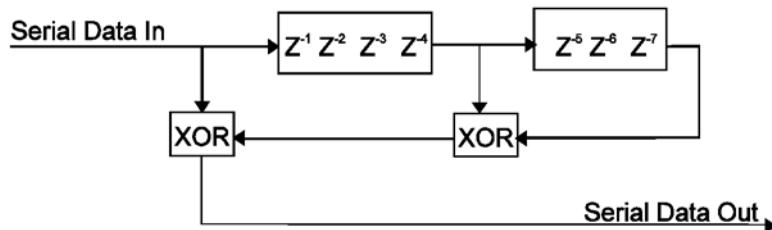

Figure 15-5—Data descrambler

15.3.5 PHY data modulation and modulation rate change

The PHY preamble shall be transmitted using the 1 Mb/s DBPSK modulation. The SIGNAL field shall indicate the modulation that shall be used to transmit the MPDU. The transmitter and receiver shall initiate the modulation indicated by the SIGNAL field starting with the first symbol (1 bit for DBPSK or 2 bits for DQPSK) of the MPDU. The MPDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 15.2.2.

15.3.6 Transmit PHY

The transmit PHY is shown in Figure 15-6.

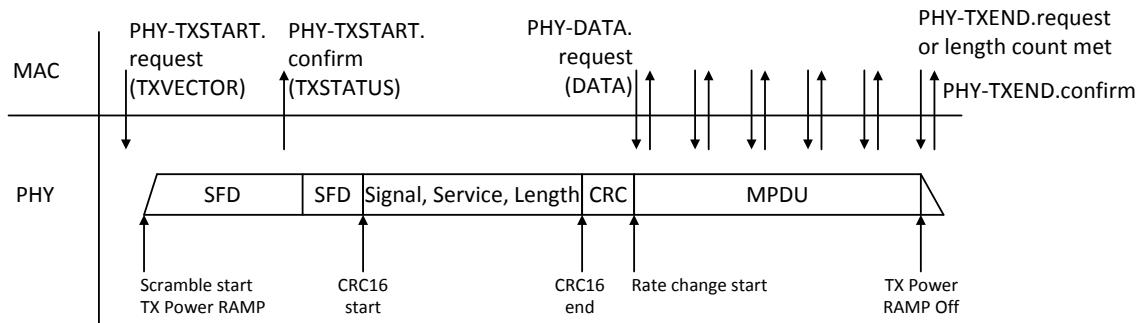

Figure 15-6—Transmit PHY

In order to transmit data, PHY-TXSTART.request primitive shall be issued so that the PHY entity shall be in the transmit state. Further, the PHY shall be set to operate at the appropriate channel through STA management via the PLME. Other transmit parameters such as DATARATE, TX antenna, and TX power are set via the PHY SAP with the PHY-TXSTART.request(TXVECTOR) primitive as described in 15.2.2.

Based on the state of CCA indicated by the PHY-CCA.indication primitive, the MAC assesses that the channel is clear. A clear channel shall be indicated by a PHY-CCA.indication(IDLE) primitive. If the channel is clear, transmission of the PPDU shall be initiated by issuing the PHY-TXSTART.request(TXVECTOR) primitive. The TXVECTOR elements for the PHY-TXSTART.request primitive are the PHY header parameters SIGNAL (DATARATE), SERVICE, LENGTH, TX_ANTENNA, TXPWR_LEVEL_INDEX, and TIME_OF_DEPARTURE_REQUESTED. The PHY header parameter LENGTH is calculated from the TXVECTOR element by multiplying by 8 for 1 Mb/s and by 4 for 2 Mb/s.

The PHY is configured with the TXVECTOR elements TX_ANTENNA, DATARATE, and TXPWR_LEVEL_INDEX. The PHY entity shall immediately initiate data scrambling and transmission of

the PHY preamble based on the parameters passed in the PHY-TXSTART.request primitive. The time required for transmit power-on ramp described in 15.4.5.8 shall be included in the PHY SYNC field.

Once the PHY preamble transmission is complete, data shall be exchanged between the MAC and the PHY by a series of PHY-DATA.request(DATA) primitives issued by the MAC and PHY-DATA.confirm primitives issued by the PHY. The modulation rate change, if any, shall be initiated with the first data symbol of the MPDU as described in 15.3.5. The PHY proceeds with MPDU transmission through a series of data octet transfers from the MAC. Transmission can be prematurely terminated by the MAC through the PHY-TXEND.request primitive. PHY-TXSTART shall be disabled by the issuance of the PHY-TXEND.request primitive. Normal termination occurs after the transmission of the final bit of the last MPDU octet according to the number supplied in the TXVECTOR LENGTH field. The packet transmission shall be completed and the PHY entity shall enter the receive state (i.e., PHY-TXSTART shall be disabled). It is recommended that chipping continue during power-down. Each PHY-TXEND.request primitive is acknowledged with a PHY-TXEND.confirm primitive from the PHY.

A typical state machine implementation of the transmit PHY is provided in Figure 15-7.

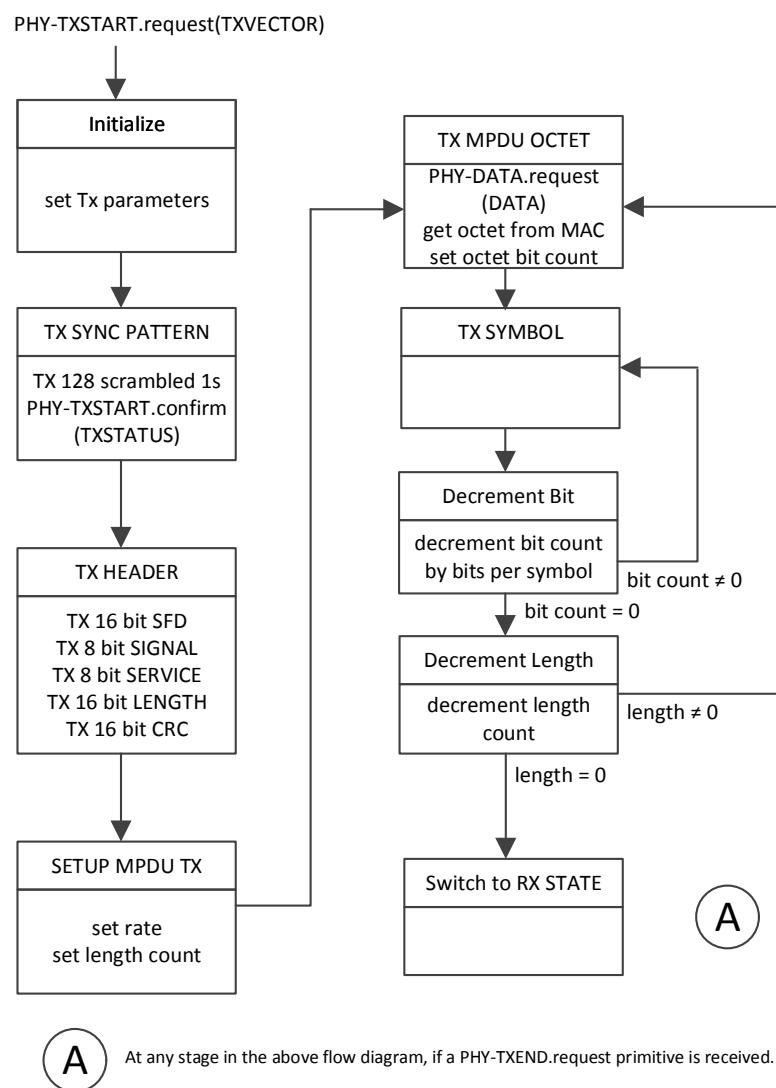

Figure 15-7—PHY transmit state machine

15.3.7 Receive PHY

The receive PHY is shown in Figure 15-8.

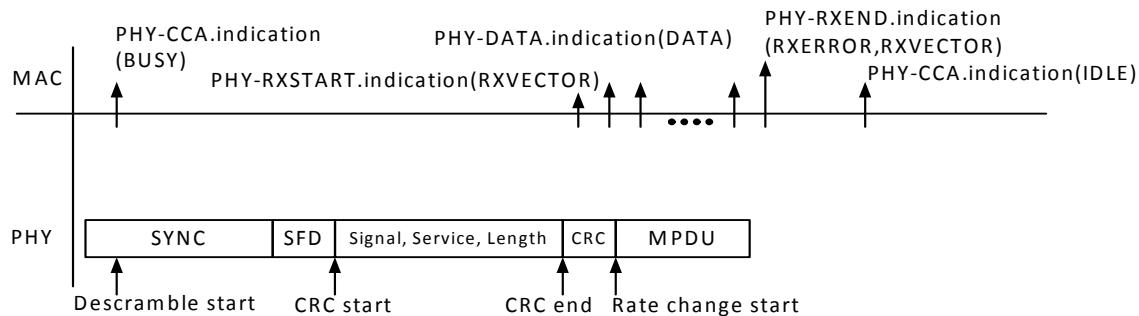

Figure 15-8—Receive PHY

In order to receive data, **PHY-TXSTART.request** primitive shall be disabled so that the PHY entity is in the receive state. Further, through STA management via the PLME, the PHY is set to the appropriate channel and the CCA method is chosen. Other receive parameters such as RSSI, RCPI, signal quality (SQ), and indicated DATARATE may be accessed via the PHY SAP.

Upon receiving the transmitted energy, according to the selected CCA mode, A **PHY-CCA.indication(BUSY)** primitive shall be issued for energy detection (ED) and/or code lock prior to correct reception of the PHY header. The PHY measures the RSSI and SQ and the parameters are reported to the MAC in the RXVECTOR.

After a **PHY-CCA.indication** primitive is issued, the PHY entity shall begin searching for the SFD field. Once the SFD field is detected, CRC-16 processing shall be initiated and the PHY SIGNAL, SERVICE and LENGTH fields are received. The CRC-16 FCS shall be processed. If the CRC-16 FCS check fails, the PHY receiver shall return to the RX IDLE state as depicted in Figure 15-9. Should the status of CCA return to the IDLE state during reception prior to completion of the full PPDU processing, the PHY receiver shall return to the RX IDLE state.

If the PHY header reception is successful (and the SIGNAL field is completely recognizable and supported), a **PHY-RXSTART.indication(RXVECTOR)** primitive shall be issued. If **dot11TimingMsmtActivated** is true, the PHY shall do the following:

- Complete receiving the PHY header and verify the validity of the PHY Header.
- If the PHY header reception is successful (and the SIGNAL field is completely recognizable and supported), a **PHY-RXSTART.indication(RXVECTOR)** primitive shall be issued and **RX_START_OF_FRAME_OFFSET** parameter within the RXVECTOR shall be forwarded (see 15.2.3).

NOTE—The **RX_START_OF_FRAME_OFFSET** value is used as described in 6.3.57 in order to estimate when the start of the preamble for the incoming frame was detected on the medium at the receive antenna connector.

The RXVECTOR associated with this primitive includes the SIGNAL field, the SERVICE field, the MPDU length in octets (calculated from the LENGTH field in microseconds), the antenna used for receive (**RX_ANTENNA**), RSSI, RCPI, and SQ.

The received MPDU bits are assembled into octets and presented to the MAC using a series of **PHY-DATA.indication(DATA)** primitive exchanges. The rate change indicated in the SIGNAL field shall be initiated with the first symbol of the MPDU as described in 15.3.5. The PHY proceeds with MPDU

reception. After the reception of the final bit of the last MPDU octet, as indicated by the PHY preamble LENGTH field, the receiver shall be returned to the RX IDLE state as shown in Figure 15-9. A PHY-RXEND.indication(NoError) primitive shall be issued. A PHY-CCA.indication(IDLE) primitive shall be issued following a change in PHY carrier sense (PHYCS) and/or PHY energy detection (PHYED) according to the selected CCA method.

In the event that a change in PHYCS or PHYED would cause the status of CCA to return to the IDLE state before the complete reception of the MPDU, as indicated by the PHY LENGTH field, the error condition shall be reported to the MAC using a PHY-RXEND.indication(CarrierLost) primitive. The CCA of the DSSS PHY shall indicate a busy medium for the intended duration of the transmitted packet.

If the PHY header is successful, but the indicated rate in the SIGNAL field is not receivable, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition by issuing a PHY-RXEND.indication(UnsupportedRate) primitive. If the PHY header is successful, but the SERVICE field is out of IEEE 802.11 DSSS specification, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition by issuing a PHY-RXEND.indication(FormatViolation) primitive. Also, in both cases, the CCA of the DSSS PHY shall indicate a busy medium for the intended duration of the transmitted frame as indicated by the LENGTH field. The intended duration is indicated by the LENGTH field (length × 1 μs).

Figure 15-9 shows the flow of a typical state machine implementation of the receive PHY.

15.4 DSSS PLME

15.4.1 PLME SAP sublayer management primitives

Table 15-4 lists the MIB attributes that may be accessed by the PHY entities and intralayer of higher level LMEs. These attributes are accessed via the PLME-GET, PLME-SET, and PLME-RESET primitives defined in Clause 6.

15.4.2 DSSS PHY MIB

All DSSS PHY MIB attributes are defined in Clause 8, with specific values defined in Table 15-4.

15.4.3 DSSS PHY

The static DSSS PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive, are shown in Table 15-5. The definitions of these characteristics are in 6.5.4.

15.4.4 PHY operating specifications, general

15.4.4.1 General

Subclause 15.4.4 provides general specifications for the DSSS PHY sublayer. These specifications apply to both the Receive and the Transmit functions and general operation of a DSSS PHY.

15.4.4.2 Operating frequency range

The DSSS PHY shall operate in the frequency range of 2.4 GHz to 2.4835 GHz as allocated by regulatory bodies in the China, United States and Europe or in the 2.471 GHz to 2.497 GHz frequency band as allocated by regulatory authority in Japan.

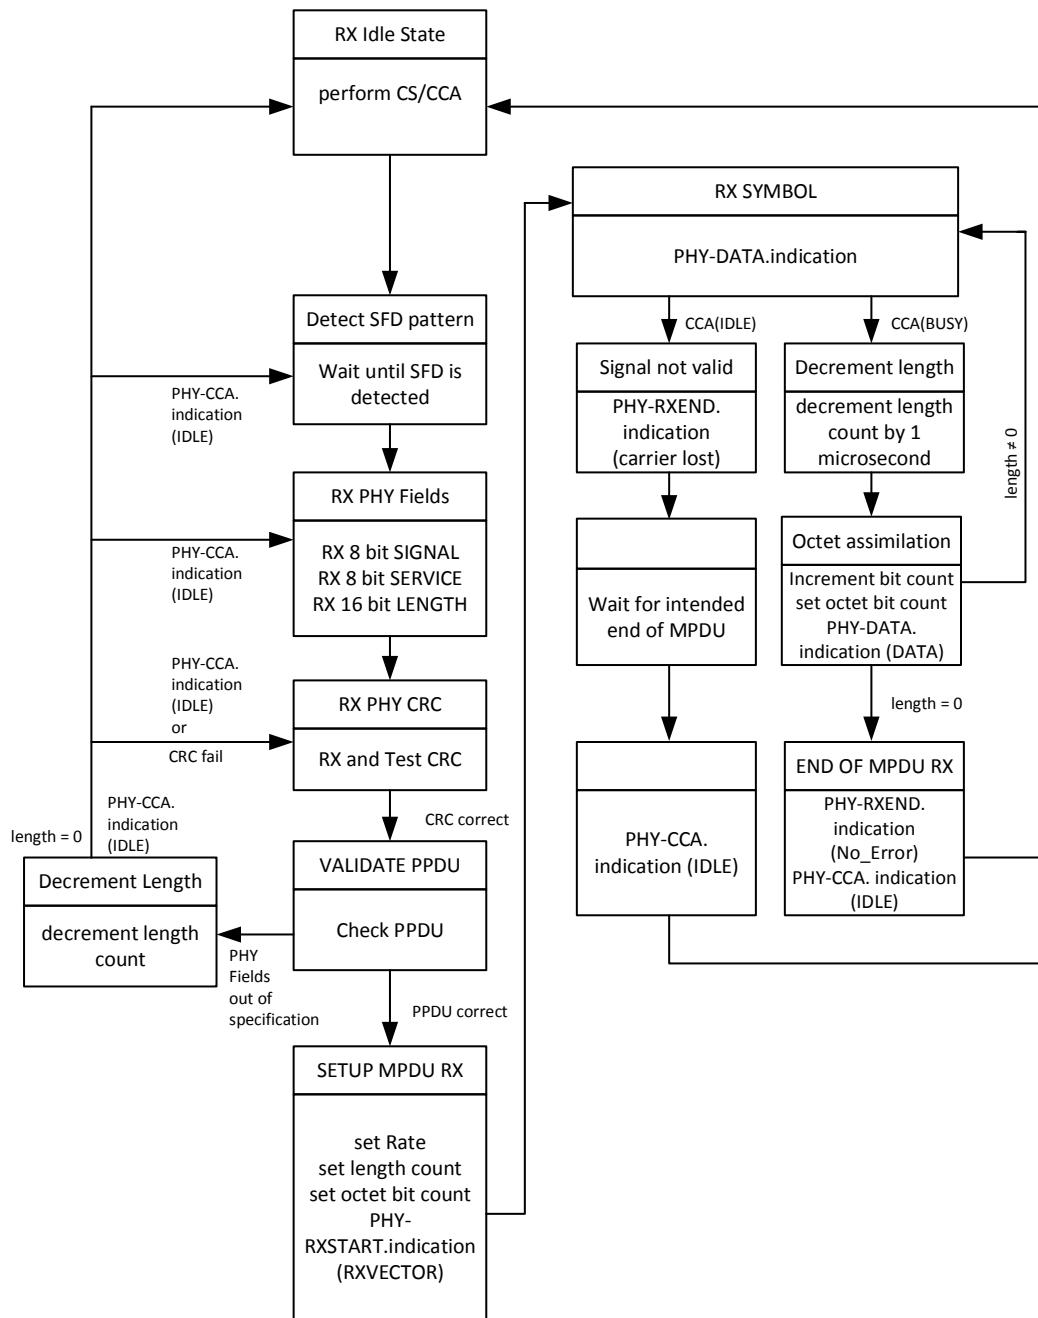

Figure 15-9—PHY receive state machine

15.4.4.3 Channel Numbering of operating channels

When `dot11OperatingClassesRequired` is true, channel numbering shall be as specified in 17.3.8.4.2 and channelization shall be as specified in 17.3.8.4.3. When `dot11OperatingClassesDefined` is false or not defined, the channel center frequencies and CHNL_ID numbers shall be as shown in Table 15-6.

In a multiple cell network topology, overlapping and/or adjacent cells using different channels can operate simultaneously without interference if the distance between the center frequencies is at least 30 MHz.

Table 15-4—MIB attribute default values/ranges

| 1 | 2412 |
| 2 | 2417 |
| 3 | 2422 |
| 4 | 2427 |
| 5 | 2432 |
| 6 | 2437 |
| 7 | 2442 |
| 8 | 2447 |
| 9 | 2452 |
| 10 | 2457 |
| 11 | 2462 |
| 12 | 2467 |
| 13 | 2472 |
| 14 | 2484 |

15.4.4.4 Spreading sequence

The following 11-chip Barker sequence shall be used as the PN code sequence:

+1, -1, +1, +1, -1, +1, +1, +1, -1, -1, -1

The leftmost chip shall be output first in time. The first chip shall be aligned at the start of a transmitted symbol. The symbol duration shall be exactly 11 chips long.

15.4.4.5 Modulation and channel data rates

Two modulation formats and data rates are specified for the DSSS PHY: a *basic access rate* and an *enhanced access rate*. The basic access rate shall be based on 1 Mb/s DBPSK modulation. The DBPSK encoder is specified in Table 15-7. The enhanced access rate shall be based on 2 Mb/s DQPSK. The DQPSK encoder is specified in Table 15-8. (In the tables, $+j\omega$ shall be defined as counterclockwise rotation.)

Table 15-7—1 Mb/s DBPSK encoding table

| Bit input | Phase change ($+j\omega$) |
|-----------|-----------------------------|
| 0 | 0 |
| 1 | π |

Table 15-8—2 Mb/s DQPSK encoding table

| Dibit pattern (d0,d1) d0 is first in time | Phase change (+j ω) |
|--|-----------------------------|
| 00 | 0 |
| 01 | $\pi/2$ |
| 11 | π |
| 10 | $3\pi/2$ ($-\pi/2$) |

15.4.4.6 Transmit and receive in-band and out-of-band spurious emissions

The DSSS PHY shall comply with in-band and out-of-band spurious emissions as set by the appropriate regulatory bodies.

15.4.4.7 TX-to-RX turnaround time

The TX-to-RX turnaround time shall be less than 10 μ s, including the power-down ramp specified in 15.4.5.8.

The TX-to-RX turnaround time shall be measured on the WM from the trailing edge of the last transmitted symbol to valid CCA detection of the incoming signal. The CCA should occur within 25 μ s (10 μ s for turnaround time plus 15 μ s for energy detect) or by the next slot boundary occurring after 25 μ s has elapsed (refer to 15.4.6.5). A receiver input signal 3 dB above the ED threshold described in 15.4.6.5 shall be present at the receiver.

15.4.4.8 RX-to-TX turnaround time

The RX-to-TX turnaround time shall be measured at the MAC/PHY interface, using the PHY-TXSTART.request primitive and shall be $\leq 5 \mu$ s. This includes the transmit power-on ramp described in 15.4.5.8.

15.4.4.9 Slot time

The value of the slot time is found in Table 15-5.

15.4.4.10 Transmit and receive antenna connector impedance

The impedance at the transmit and receive antenna connector(s) shall be 50 Ω if the connector is exposed.

15.4.5 PHY transmit specifications

15.4.5.1 Introduction

The transmit functions and parameters associated with the PHY sublayer are described in 15.4.5.2 to 15.4.5.10.

15.4.5.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

15.4.5.3 Minimum transmitted power level

The minimum transmitted power shall be no less than 1 mW.

15.4.5.4 Transmit power level control

Power control shall be provided for transmitted power greater than 100 mW. A maximum of four power levels may be provided. At a minimum, a radio capable of transmission greater than 100 mW shall be capable of switching power back to 100 mW or less.

15.4.5.5 Transmit spectrum mask

The transmitted spectral products shall be less than -30 dB_r (decibel relative to the SINx/x peak) for $f_c - 22$ MHz $< f < f_c - 11$ MHz, $f_c + 11$ MHz $< f < f_c + 22$ MHz, -50 dB_r for $f < f_c - 22$ MHz, and $f > f_c + 22$ MHz, where f_c is the channel center frequency. The transmit spectral mask is shown in Figure 15-10. The measurements shall be made using 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

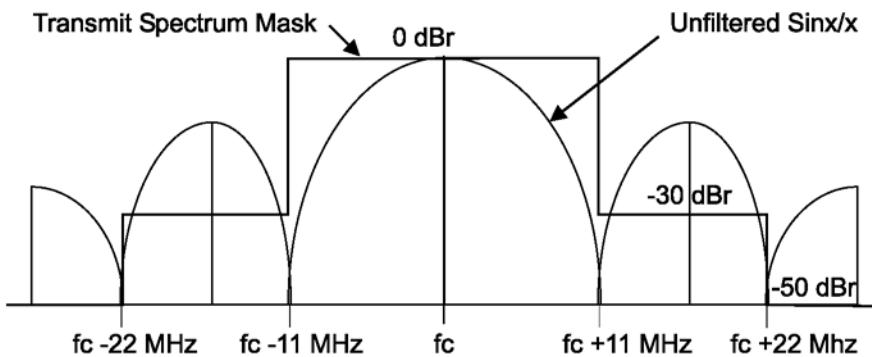

Figure 15-10—Transmit spectrum mask

Channel 14 is unique. The Japanese standard ARIB RCR-STD 33 (5.0) [B7] states that $B90/2\pi$ normalized to the ‘transmission speed of modulation signal’ shall be > 10 , where $B90$ is the 90% occupied channel bandwidth. Therefore, for channel 14, $B90/2\pi > 13.75$ MHz for CCK spreading and >10.0 MHz for Barker spreading.

15.4.5.6 Transmit center frequency tolerance

The transmitted center frequency tolerance shall be ± 25 ppm maximum.

15.4.5.7 Chip clock frequency tolerance

The PN code chip clock frequency tolerance shall be ± 25 ppm maximum.

15.4.5.8 Transmit power-on and power-down ramp

The transmit power-on ramp for 10% to 90% of maximum power shall be no greater than 2 μ s. The transmit power-on ramp is shown in Figure 15-11.

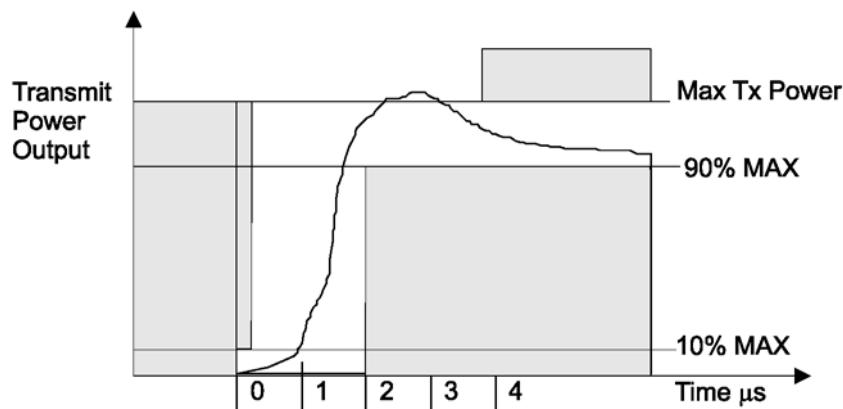

Figure 15-11—Transmit power-on ramp

The transmit power-down ramp for 90% to 10% maximum power shall be no greater than 2 μ s. The transmit power-down ramp is shown in Figure 15-12.

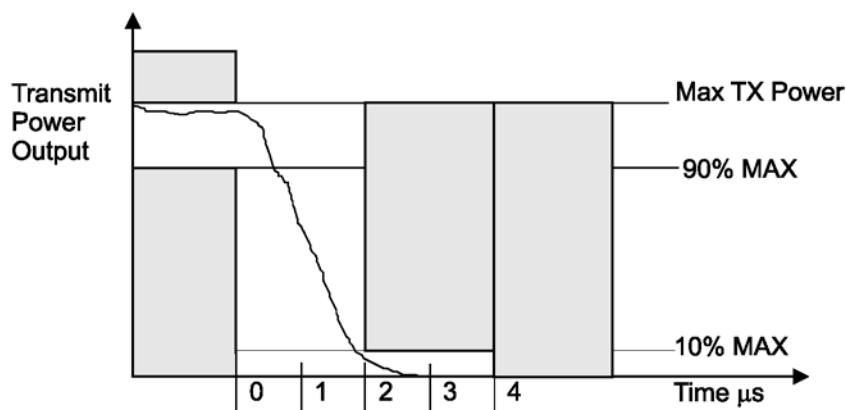

Figure 15-12—Transmit power-down ramp

The transmit power ramps shall be constructed such that the DSSS PHY emissions comply with the spurious frequency product specification defined in 15.4.4.6.

15.4.5.9 RF carrier suppression

The RF carrier suppression, measured at the channel center frequency, shall be at least 15 dB below the peak $\sin(x)/x$ power spectrum. The RF carrier suppression shall be measured while transmitting a repetitive 01 data sequence with the scrambler disabled using DQPSK modulation. A 100 kHz resolution bandwidth shall be used to perform this measurement.

15.4.5.10 Transmit modulation accuracy

The transmit modulation accuracy requirement for the DSSS PHY shall be based on the difference between the actual transmitted waveform and the ideal signal waveform. Modulation accuracy shall be determined by measuring the peak vector error magnitude measured during each chip period. Worst-case vector error magnitude shall not exceed 0.35 for the normalized sampled chip data. The ideal complex I and Q constellation points associated with DQPSK modulation $(0.707, 0.707)$, $(0.707, -0.707)$, $(-0.707, 0.707)$, $(-0.707, -0.707)$ shall be used as the reference. These measurements shall be from baseband I and Q sampled data after recovery through a reference receiver system.

Figure 15-13 illustrates the ideal DQPSK constellation points and range of worst-case error specified for modulation accuracy.

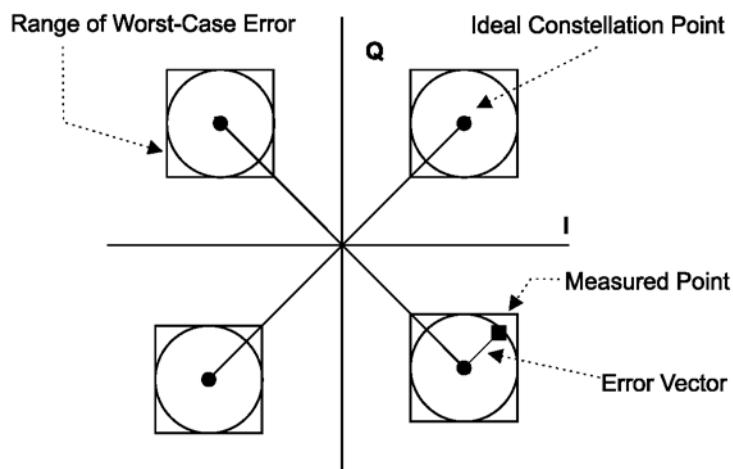

Figure 15-13—Modulation accuracy measurement example

Error vector measurement requires a reference receiver capable of carrier lock. All measurements shall be made under carrier lock conditions. The distortion induced in the constellation by the reference receiver shall be calibrated and measured. The test data error vectors described below shall be corrected to compensate for the reference receiver distortion.

The IEEE 802.11 vendor compatible radio shall provide an exposed TX chip clock, which shall be used to sample the I and Q outputs of the reference receiver.

The measurement shall be made under the conditions of continuous DQPSK transmission using scrambled all 1s.

The eye pattern of the I channel shall be used to determine the *I* and *Q* sampling point. The chip clock provided by the vendor radio shall be time delayed such that the samples fall at a 1/2 chip period offset from the mean of the zero crossing positions of the eye (see Figure 15-14). This is the ideal center of the eye and might not be the point of maximum eye opening.

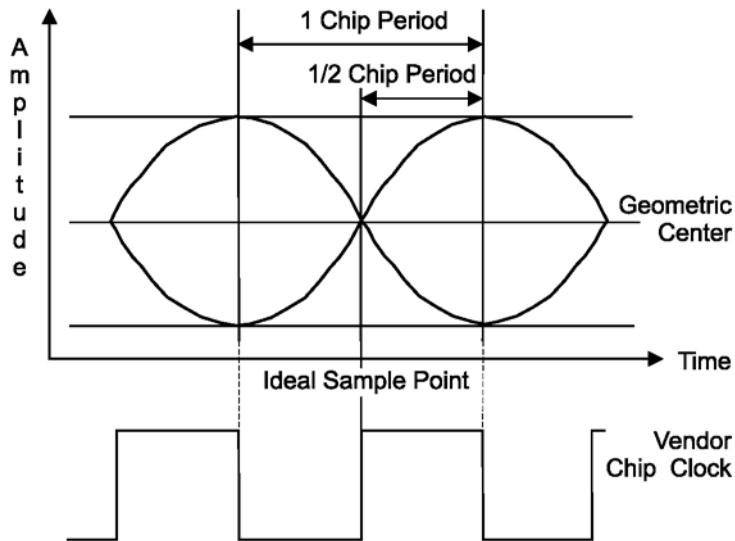

Figure 15-14—Chip clock alignment with baseband eye pattern

Using the aligned chip clock, 1000 samples of the I and Q baseband outputs from the reference receiver are captured. The vector error magnitudes shall be calculated as follows:

Calculate the dc offsets for I and Q samples.

$$I_{\text{mean}} = \sum_{n=1}^{1000} I(n) / 1000$$

$$Q_{\text{mean}} = \sum_{n=1}^{1000} Q(n) / 1000$$

Calculate the dc corrected I and Q samples for all $n = 1000$ sample pairs.

$$I_{\text{dc}}(n) = I(n) - I_{\text{mean}}$$

$$Q_{\text{dc}}(n) = Q(n) - Q_{\text{mean}}$$

Calculate the average magnitude of I and Q samples.

$$I_{\text{mag}} = \sum_{n=1}^{1000} |I_{\text{dc}}(n)| / 1000$$

$$Q_{\text{mag}} = \sum_{n=1}^{1000} |Q_{\text{dc}}(n)| / 1000$$

Calculate the normalized error vector magnitude for the $I_{\text{dc}}(n)/Q_{\text{dc}}(n)$ pairs.

$$V_{\text{err}}(n) = [\{|I_{\text{dc}}(n)| - I_{\text{mag}}\}^2 + \{|Q_{\text{dc}}(n)| - Q_{\text{mag}}\}^2]^{1/2}$$

where

the average power of the constellation is 1

NOTE—A correction factor might be needed to compensate for the error induced by a test reference receiver system.

For all $n = 1000$ samples, the following condition shall be met:

$$V_{err}(n) < 0.35$$

15.4.5.11 Time of Departure accuracy

The Time of Departure accuracy test evaluates TIME_OF_DEPARTURE against aTxPHYTxStartRMS and aTxPHYTxStartRMS against TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH as defined Annex P with the following test parameters:

- MULTICHANNEL_SAMPLING_RATE is $22 \times 10^6 \left(1 + \left\lceil \frac{f_H - f_L}{22 \text{ MHz}} \right\rceil\right)$ sample/s

where

- f_H is the nominal center frequency in Hz of the highest channel in the channel set
- f_L is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across $f_H - f_L \geq 50 \text{ MHz}$

- FIRST_TRANSITION_FIELD is the SYNC field.
- SECOND_TRANSITION_FIELD is the SFD field.
- TRAINING_FIELD is the concatenation of the SYNC and SFD fields, using a chip pulse that should approximate a rectangular pulse of duration $1/11 \text{ MHz}$ convolved with a brick-wall low pass filter of bandwidth 11 MHz .
- TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH is 80 ns.

NOTE—The indicated chip pulse applies to the time of departure accuracy test equipment, and not the transmitter or receiver.

15.4.6 PHY receiver specifications

15.4.6.1 Introduction

The receive functions and parameters associated with the PHY sublayer are described in 15.4.6.2 to 15.4.6.5.

15.4.6.2 Receiver minimum input level sensitivity

The FER shall be less than 8×10^{-2} at an MPDU length of 1024 octets for an input level of -80 dBm measured at the antenna connector. This FER shall be specified for 2 Mb/s DQPSK modulation. The test for the minimum input level sensitivity shall be conducted with the ED threshold set $\leq -80 \text{ dBm}$.

15.4.6.3 Receiver maximum input level

The receiver shall provide a maximum FER of 8×10^{-2} at an MPDU length of 1024 octets for a maximum input level of -4 dBm measured at the antenna. This FER shall be specified for 2 Mb/s DQPSK modulation.

15.4.6.4 Receiver adjacent channel rejection

Adjacent channel rejection is defined between any two channels with ≥ 30 MHz separation in each channel group defined in 15.4.4.3.

The adjacent channel rejection shall be ≥ 35 dB with an FER of 8×10^{-2} using 2 Mb/s DQPSK modulation described in 15.4.4.5 and an MPDU length of 1024 octets.

The adjacent channel rejection shall be measured using the following method:

Input a 2 Mb/s DQPSK modulated signal at a level 6 dB greater than specified in 15.4.6.2. In an adjacent channel (≥ 30 MHz separation as defined by the channel numbering), input a signal modulated in a similar fashion that adheres to the transmit mask specified in 15.4.5.5 to a level 41 dB above the level specified in 15.4.6.2. The adjacent channel signal shall be derived from a separate signal source. It shall not be a frequency shifted version of the reference channel. Under these conditions, the FER shall be less than or equal to 8×10^{-2} .

15.4.6.5 CCA

The DSSS PHY shall provide the capability to perform CCA according to both:

A — at least one of the following options:

- *CCA Mode 1*: Energy above threshold. CCA shall report a busy medium upon detection of any energy above the ED threshold.
- *CCA Mode 2*: CS only. CCA shall report a busy medium only upon detection of a DSSS signal. This signal may be above or below the ED threshold.
- *CCA Mode 3*: CS with energy above threshold. CCA shall report a busy medium upon detection of a DSSS signal with energy above the ED threshold.

and

B — *CCA Mode 6*: CCA shall report a busy medium upon detection of any energy above -62 dBm.

A busy channel shall be indicated by issuing a PHY-CCA.indication(BUSY) primitive.

A clear channel shall be indicated by issuing a PHY-CCA.indication(IDLE) primitive.

The value of dot11CCAModeSupported shall indicate the appropriate operation modes. The PHY shall be configured according to dot11CurrentCCAMode.

The CCA shall indicate a clear channel if there is no energy detect or CS. The CCA parameters are subject to the following criteria:

- a) The ED threshold shall be ≤ -80 dBm for TX power > 100 mW, -76 dBm for 50 mW $<$ TX power ≤ 100 mW, and -70 dBm for TX power ≤ 50 mW.
- b) With a valid signal (according to the CCA mode of operation) present at the receiver antenna within 5 μ s of the start of a MAC slot boundary, the PHY-CCA.indication(BUSY) primitive shall be generated before the end of the slot time. Refer to Figure 10-19 (in 10.3.7) and Figure 10-26 for a definition of slot boundary.
- c) In the event that a correct PHY header is received, the DSSS PHY shall not generate a PHY-CCA.indication (IDLE) primitive until the end of the PPDU as determined by TXTIME in 16.4.7.

Compliance to DSSS PHY CCA shall be demonstrated by applying a DSSS signal, above the appropriate ED threshold (item a), so that all conditions described in item b and item c are demonstrated.

15.4.6.6 Received Channel Power Indicator Measurement

The RCPI is a measure of the received RF power in the selected channel for a received frame. This parameter shall be a measure by the PHY of the received RF power in the channel measured over the entire received frame or by other equivalent means that meet the specified accuracy.

The encoding of received power to RCPI is defined in 9.4.2.38.

RCPI shall equal the received RF power within an accuracy of ± 5 dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel bandwidth multiplied by 1.1.

15.4.6.7 DSSS PHY TXTIME calculation

The value of the TXTIME parameter returned by the PLME-TXTIME.confirm primitive shall be calculated according to the following equations:

$$\text{TXTIME} = \text{PreambleLength} + \text{PHYHeaderTime} + \left\lceil \frac{\text{LENGTH} \times 8}{\text{DATARATE}} \right\rceil$$

where

| | |
|-----------------------------|---|
| LENGTH and DATARATE | are values from the TXVECTOR parameter of the corresponding PLME-TXTIME.request primitive |
| LENGTH | is in units of octets |
| DATARATE | is in units of Mb/s |
| The value of PreambleLength | is 144 μ s |
| The value of PHYHeaderTime | is 48 μ s. |

16. High rate direct sequence spread spectrum (HR/DSSS) PHY specification

16.1 Overview

16.1.1 General

This clause specifies the high rate extension of the PHY for the DSSS system (see Clause 15), hereinafter known as the HR/DSSS PHY for the 2.4 GHz band designated for ISM applications.

This extension of the DSSS system builds on the data rate capabilities, as described in Clause 15, to provide 5.5 Mb/s and 11 Mb/s payload data rates in addition to the 1 Mb/s and 2 Mb/s rates. To provide the higher rates, 8-chip complementary code keying (CCK) is employed as the modulation scheme. The chipping rate is 11 MHz, which is the same as the DSSS system described in Clause 15, thus providing the same occupied channel bandwidth. The basic new capability described in this clause is called *HR/DSSS*. One mode of the HR/DSSS PHY uses the same PHY preamble and header as the DSSS PHY, so both PHYs can co-exist in the same BSS and can use the rate switching mechanism as provided.

In addition to providing higher speed extensions to the DSSS system, a number of optional features allow the performance of the RF LAN system to be improved as technology allows the implementation of these options to become cost effective.

Another optional mode is provided that allows data throughput at the higher rates (2, 5.5, and 11 Mb/s) to be significantly increased by using a shorter PHY preamble. This mode is called *HR/DSSS/short*. This short preamble mode can coexist with DSSS, HR/DSSS under limited circumstances, such as on different channels or with appropriate CCA mechanisms.

16.1.2 Scope

This clause specifies the PHY entity for the HR/DSSS extension and explains how this standard accommodates the HR/DSSS PHY.

The HR/DSSS PHY consists of the following two protocol functions:

- a) A PHY function that defines a method for mapping the MPDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs. The PHY exchanges PPDUs that contain PSDUs. The MAC uses the PHY service, so each MPDU corresponds to a PSDU that is carried in a PPDU.
- b) A function that defines the characteristics of, and method of transmitting and receiving data through, a WM between two or more STAs, each using the HR/DSSS PHY system.

16.1.3 HR/DSSS PHY functions

16.1.3.1 General

The HR/DSSS PHY contains two functional entities: the PHY function and the layer management function. Each of these functions is described in detail in 16.2 and 16.3.

The HR/DSSS PHY service shall be provided to the MAC through the PHY service primitives described in Clause 8.

16.1.3.2 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME.

16.1.4 Service specification method and notation

The models represented by figures and state diagrams are intended to be illustrations of functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation, but do not necessarily reflect any particular implementation.

The service of a layer or sublayer is a set of capabilities that it offers to a user in the next-higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

16.2 HR/DSSS PHY

16.2.1 Overview

Subclause 16.2 provides a convergence procedure for the 2 Mb/s, 5.5 Mb/s, and 11 Mb/s specification, in which PSDUs are converted to and from PPDUs. During transmission, the PSDU shall be appended to a PHY preamble and header to create the PPDU. Two different preambles and headers are defined: the mandatory supported long preamble and header, which interoperates with the current 1 Mb/s and 2 Mb/s DSSS specification, and an optional short preamble and header. At the receiver, the PHY preamble and header are processed to aid in demodulation and delivery of the PSDU.

The optional short preamble and header provides maximum throughput when interoperability with legacy and nonshort-preamble-capable STAs is not a consideration. That is, it is expected to be used only in networks of STAs that support the optional mode.

16.2.2 PPDU format

16.2.2.1 General

Two different preambles and headers are defined: the mandatory supported long preamble and header, which is interoperable with the current 1 Mb/s and 2 Mb/s DSSS specification, and an optional short preamble and header.

16.2.2.2 Long PPDU format

Figure 16-1 shows the format for the interoperable (long) PPDU, including the HR/DSSS PHY preamble, the HR/DSSS PHY header, and the PSDU. The PHY preamble contains the following fields: SYNC and SFD. The PHY header contains the following fields: signaling (SIGNAL), service (SERVICE), length (LENGTH), and CRC-16. Each of these fields is described in detail in 16.2.3. The format for the PPDU, including the long HR/DSSS PHY preamble, the long HR/DSSS PHY header, and the PSDU, does not differ from the format for 1 Mb/s and 2 Mb/s. The only exceptions are:

- a) The encoding of the rate in the SIGNAL field;
- b) The use of a bit in the SERVICE field to resolve an ambiguity in PSDU length in octets, when the length is expressed in whole microseconds;
- c) The use of a bit in the SERVICE field to indicate that the transit frequency and bit clocks are locked.

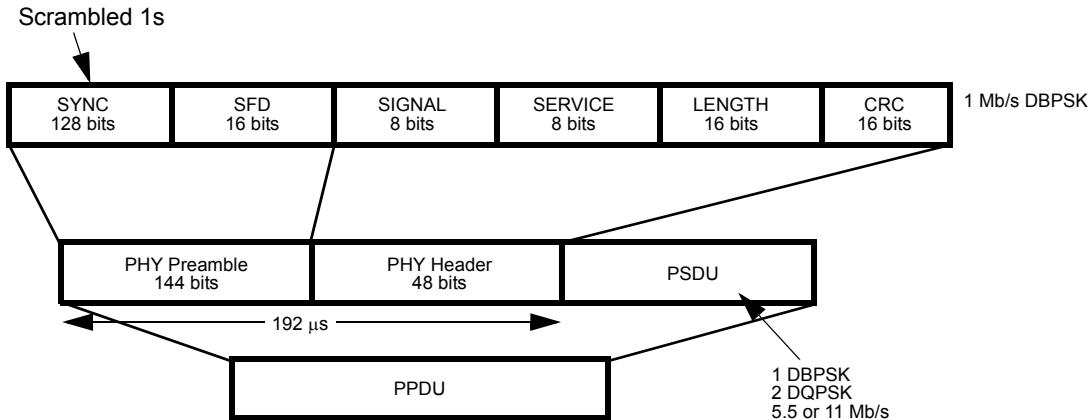

Figure 16-1—Long PPDU format

16.2.2.3 Short PPDU format

The short PHY preamble and header (HR/DSSS/short) is optional. The short preamble and header may be used to minimize overhead and, thus, maximize the network data throughput. The format of the PPDU, with HR/DSSS/short, is depicted in Figure 16-2. A Clause 18 STA shall support the short PPDU format.

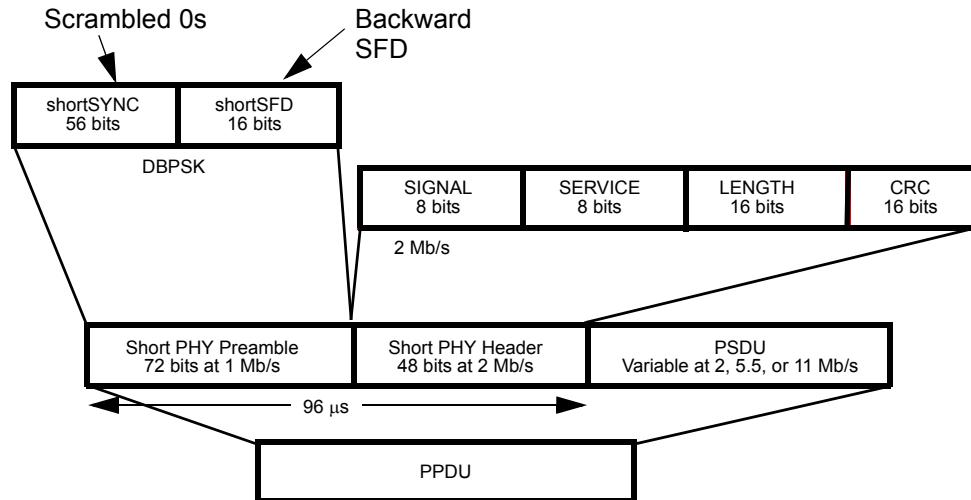

Figure 16-2—Short PPDU format

A transmitter using the short PPDU is interoperable with only another receiver that is also capable of receiving this short PPDU. To interoperate with a receiver that is not capable of receiving a short preamble and header, the transmitter shall use the long PHY preamble and header. The short PHY preamble uses the 1 Mb/s Barker code spreading with DBPSK modulation. The short PHY header uses the 2 Mb/s Barker code spreading with DQPSK modulation, and the PSDU is transmitted at 2 Mb/s, 5.5 Mb/s, or 11 Mb/s.

16.2.3 PPDU field definitions

16.2.3.1 General

In the PHY field definition subclauses (16.2.3.2 to 16.2.3.15), the definitions of the long (Clause 15) PHY fields are given first, followed by the definitions of the short PHY fields. The names for the short PHY fields are preceded by the term *short*.

16.2.3.2 Long PHY SYNC field

The SYNC field shall consist of 128 bits of scrambled 1 bits. This field is provided so the receiver can perform the necessary synchronization operations. The initial state of the scrambler (seed) shall be [1101100], where the leftmost bit specifies the value to put in the first delay element (Z^1) in Figure 16-5 (in 16.2.4), and the rightmost bit specifies the value to put in the last delay element in the scrambler.

To support the reception of DSSS signals generated with implementations based on Clause 15, the receiver shall also be capable of synchronization on a SYNC field derived from any nonzero scrambler initial state.

16.2.3.3 Long PHY SFD

The SFD shall be provided to indicate the start of PHY-dependent parameters within the PHY preamble. The SFD shall be a 16-bit field, [1111 0011 1010 0000], where the rightmost bit shall be transmitted first in time.

16.2.3.4 Long PHY SIGNAL field

The 8-bit SIGNAL field indicates to the PHY the modulation that shall be used for transmission (and reception) of the PSDU. The data rate shall be equal to the SIGNAL field value multiplied by 100 kb/s. The high rate PHY supports four mandatory rates given by the following 8-bit words, which represent the rate in units of 100 kb/s, where the LSB shall be transmitted first in time:

- a) X'0A' (MSB to LSB) for 1 Mb/s;
- b) X'14' (MSB to LSB) for 2 Mb/s;
- c) X'37' (MSB to LSB) for 5.5 Mb/s;
- d) X'6E' (MSB to LSB) for 11 Mb/s.

The HR/DSSS PHY rate change capability is described in 16.2.3.15. This field shall be protected by the CRC-16 FCS described in 16.2.3.7.

16.2.3.5 Long PHY SERVICE field

Two bits have been defined in the SERVICE field to support the high rate extension; see Table 16-1. The rightmost bit (bit 7) shall be used to supplement the LENGTH field described in 16.2.3.6. Bit 2 shall be used to indicate that the transmit frequency and symbol clocks are derived from the same oscillator. This locked clocks bit shall be set by the PHY based on its implementation configuration. The SERVICE field shall be transmitted B0 first in time, and shall be protected by the CRC-16 FCS described in 16.2.3.7. B0, B1, B3, B4, B5, and B6 are reserved and shall be set to 0 on transmission and ignored on reception.

Table 16-1—SERVICE field definitions

| B0 | B1 | B2 | B3 | B4 | B5 | B6 | B7 |
|----------|----------|---|----------|----------|----------|----------|----------------------|
| Reserved | Reserved | Locked clocks bit 0 = not locked 1 = locked | Reserved | Reserved | Reserved | Reserved | Length extension bit |

16.2.3.6 Long PHY LENGTH field

The PHY LENGTH field shall contain an unsigned 16-bit integer that indicates the number of microseconds required to transmit the PSDU. The transmitted value shall be determined from the LENGTH and DATARATE parameters in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 16.3.5.

The LENGTH field provided in the TXVECTOR is in octets and is converted to microseconds for inclusion in the PHY LENGTH field. The LENGTH field is calculated as follows. Because there is an ambiguity in the number of octets that is described by a length in integer microseconds for any data rate over 8 Mb/s, a length extension bit is present in the SERVICE field to indicate when the smaller potential number of octets is correct as follows:

- 5.5 Mb/s CCK LENGTH = $\left\lceil \text{number of octets} \times \frac{8}{5.5} \right\rceil$.
- 11 Mb/s CCK LENGTH = $\left\lceil \text{number of octets} \times \frac{8}{11} \right\rceil$; the length extension bit shall be set to 0 if (LENGTH – (number of octets × 8/11)) < 8/11 and shall be set to 1 otherwise.

The length extension bit is reserved when the data rate is not 11 Mb/s.

At the receiver, the number of octets in the MPDU is calculated as follows:

- 5.5 Mb/s CCK number of octets = $\left\lfloor \text{LENGTH} \times \frac{5.5}{8} \right\rfloor$.
- 11 Mb/s CCK number of octets = $\left\lfloor \text{LENGTH} \times \frac{11}{8} \right\rfloor$, minus 1 if the length extension bit is a 1.

An example for an 11 Mb/s calculation described in pseudocode form is shown below. At the transmitter, the values of the LENGTH field and length extension bit are calculated as follows:

$$\text{LENGTH}' = (\text{number of octets} \times 8) / R$$

$$\text{LENGTH} = \lceil \text{LENGTH}' \rceil$$

If

$$(R = 11) \text{ and } ((\text{LENGTH} - \text{LENGTH}') \geq 8/11)$$

then

$$\text{length extension} = 1$$

else

$$\text{length extension} = 0$$

where

$$R \quad \text{is the data rate (Mb/s)}$$

At the receiver, the number of octets in the MPDU is calculated as follows:

$$\text{number of octets} = \left\lfloor \frac{\text{LENGTH} \times R}{8} \right\rfloor - \text{length extension}$$

where

R is the data rate (Mb/s)

Table 16-2 shows an example calculation for several packet lengths of CCK at 11 Mb/s.

Table 16-2—Example of LENGTH calculations for CCK

| TX octets | $\frac{\text{Octets} \times 8}{11}$ | LENGTH | Length extension bit | $\frac{\text{LENGTH} \times 11}{8}$ | $\left\lfloor \frac{\text{LENGTH} \times 11}{8} \right\rfloor$ | RX octets |
|-----------|-------------------------------------|--------|----------------------|-------------------------------------|--|-----------|
| 1023 | 744 | 744 | 0 | 1023 | 1023 | 1023 |
| 1024 | 744.7273 | 745 | 0 | 1024.375 | 1024 | 1024 |
| 1025 | 745.4545 | 746 | 0 | 1025.75 | 1025 | 1025 |
| 1026 | 746.1818 | 747 | 1 | 1027.125 | 1027 | 1026 |

This example illustrates why normal rounding or truncation of the number does produce the right result. The LENGTH field is defined in units of microseconds and corresponds to the actual length, and the number of octets is exact.

The LSB shall be transmitted first in time. This field shall be protected by the CRC-16 FCS described in 16.2.3.7.

16.2.3.7 PHY CRC (CRC-16) field

The SIGNAL, SERVICE, and LENGTH fields shall be protected with a CRC-16 FCS. The CRC-16 FCS shall be the 1s complement of the remainder generated by the modulo 2 division of the protected PHY fields by the polynomial

$$x^{16} + x^{12} + x^5 + 1$$

The protected bits shall be processed in transmit order. All FCS calculations shall be made prior to data scrambling. A schematic of the processing is shown in Figure 16-3.

As an example, the SIGNAL, SERVICE, and LENGTH fields for a DBPSK signal with a PPDU length of 192 µs (24 octets) would be given by the following:

0101 0000 0000 0000 0011 0000 0000 [leftmost bit (B0) transmitted first in time]
 B0.....B48

The 1s complement FCS for these protected PHY preamble bits would be the following:

0101 1011 0101 0111 [leftmost bit (B0) transmitted first in time]
 B0.....B16

Figure 16-3 depicts this example.

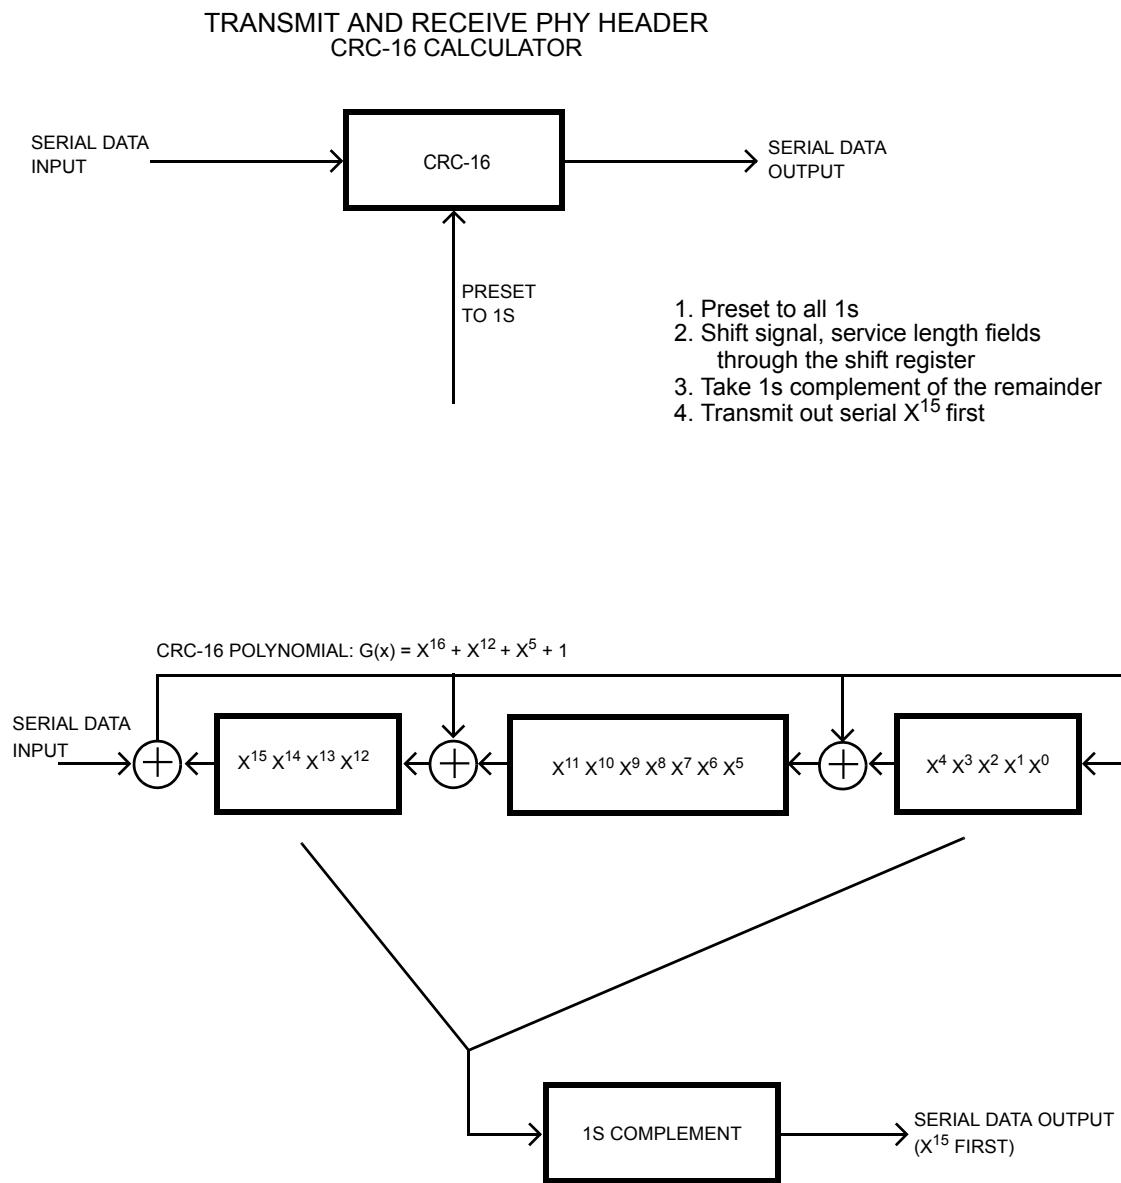

Figure 16-3—CRC-16 implementation

An illustrative example of the CRC-16 FCS using the information from Figure 16-3 is shown in Figure 16-4.

| Data | CRC Registers | |
|------|-------------------|--|

Figure 16-4—Example of CRC calculation

16.2.3.8 Long PHY data modulation and modulation rate change

The long PHY preamble and header shall be transmitted using the 1 Mb/s DBPSK modulation. The SIGNAL field indicates the rate that is used to transmit the PSDU. The transmitter and receiver shall initiate the rate indicated by the SIGNAL field, starting with the first octet of the PSDU. The PSDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 16.3.5.

16.2.3.9 Short PHY synchronization (shortSYNC)

The shortSYNC field shall consist of 56 bits of scrambled 0 bits. This field is provided so the receiver can perform the necessary synchronization operations. The initial state of the scrambler (seed) shall be [001 1011], where the left end bit specifies the value to place in the first delay element (Z^1) in Figure 16-5 (in 16.2.4), and the right end bit specifies the value to place in the last delay element (Z^7).

16.2.3.10 Short PHY SFD field (shortSFD)

The shortSFD shall be a 16-bit field and be the time reverse of the field of the SFD in the long PHY preamble (16.2.3.3). The field is the bit pattern 0000 0101 1100 1111. The right end bit shall be transmitted first in time. A receiver not configured to use the short header option does not detect this SFD.

16.2.3.11 Short PHY SIGNAL field (shortSIGNAL)

The 8-bit SIGNAL field of the short header indicates to the PHY the data rate that shall be used for transmission (and reception) of the PSDU. A PHY operating with the HR/DSSS/short option supports three mandatory rates given by the following 8-bit words, where the LSB shall be transmitted first in time and the number represents the rate in units of 100 kb/s:

- a) X'14' (MSB to LSB) for 2 Mb/s;
- b) X'37' (MSB to LSB) for 5.5 Mb/s;
- c) X'6E' (MSB to LSB) for 11 Mb/s.

16.2.3.12 Short PHY SERVICE field (shortSERVICE)

The SERVICE field in the short header shall be the same as the SERVICE field described in 16.2.3.5.

16.2.3.13 Short PHY LENGTH field (shortLENGTH)

The LENGTH field in the short header shall be the same as the LENGTH field described in 16.2.3.6.

16.2.3.14 Short CRC-16 field (shortCRC)

The CRC in the short header shall be the same as the CRC field defined in 16.2.3.7. The CRC-16 is calculated over the shortSIGNAL, shortSERVICE, and shortLENGTH fields.

16.2.3.15 Short PHY data modulation and modulation rate change

The short PHY preamble shall be transmitted using the 1 Mb/s DBPSK modulation. The short PHY header shall be transmitted using the 2 Mb/s modulation. The SIGNAL field indicates the rate that is used to transmit the PSDU. The transmitter and receiver shall initiate the rate indicated by the SIGNAL field, starting with the first octet of the PSDU. The PSDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 16.3.5.

16.2.4 PHY/HR/DSSS PHY data scrambler and descrambler

The polynomial $G(z) = z^{-7} + z^{-4} + 1$ shall be used to scramble all bits transmitted. The feedthrough configuration of the scrambler and descrambler is self-synchronizing, which requires no prior knowledge of the transmitter initialization of the scrambler for receive processing. Figure 16-5 and Figure 16-6 show typical implementations of the data scrambler and descrambler, but other implementations are possible.

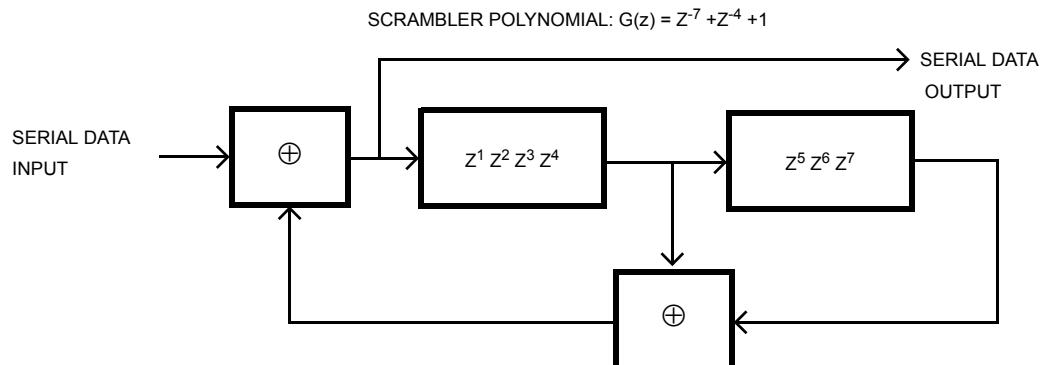

Figure 16-5—Data scrambler

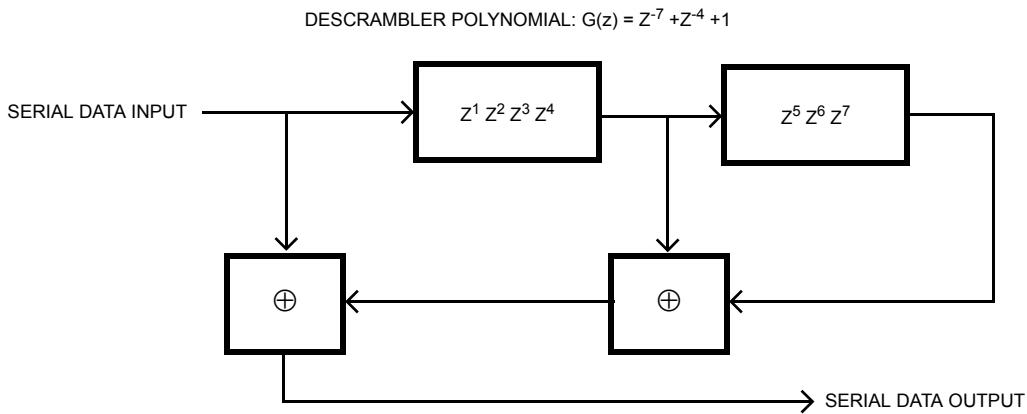

Figure 16-6—Data descrambler

The scrambler shall be initialized as specified in 16.2.3.9 for the short PPDU format and 16.2.3.2 for the long PPDU format. For a long preamble, this shall result in the scrambler registers Z^1 to Z^7 in Figure 16-5 having the data pattern [1101100] (i.e., $Z^1 = 1 \dots Z^7 = 0$) when the scrambler is first started. The scrambler shall be initialized with the reverse pattern [0011011] when transmitting the optional short preamble.

16.2.5 Transmit PHY

The transmit procedures for a HR/DSSS PHY using the long PPDU format are the same as the transmit procedures described in 15.3.6 and 15.3.7 and do not change apart from the ability to transmit 5.5 Mb/s and 11 Mb/s.

The procedures for a transmitter employing HR/DSSS/short are the same except for length and rate changes. The decision to use the long or short PPDU format is beyond the scope of this standard.

The transmit PHY is shown in Figure 16-7.

A PHY-TXSTART.request(TXVECTOR) primitive is issued by the MAC to start the transmission of a PPDU. In addition to parameters DATARATE and LENGTH, other transmit parameters such as PREAMBLE_TYPE are set via the PHY SAP with the PHY-TXSTART.request(TXVECTOR) primitive, as described in 16.3.5. The SIGNAL, SERVICE, and LENGTH fields of the PHY header are calculated as described in 16.2.3.

The PHY is configured with the TXVECTOR elements TX_ANTENNA, DATARATE, and TXPWR_LEVEL_INDEX. The PHY entity shall immediately initiate data scrambling and transmission of the PHY preamble based on the parameters passed in the PHY-TXSTART.request primitive. The time required for transmit power-on ramp, described in 16.3.7.7, shall be included in the PHY SYNC field.

Once the PHY preamble transmission is complete, data shall be exchanged between the MAC and the PHY by a series of PHY-DATA.request(DATA) primitives issued by the MAC and PHY-DATA.confirm primitives issued by the PHY. The modulation and rate change, if any, shall be initiated with the first data symbol of the PSDU, as described in 16.2.3.8 and 16.2.3.15. The PHY proceeds with PSDU transmission through a series of data octet transfers from the MAC. Transmission can be prematurely terminated by the MAC through the PHY-TXEND.request primitive. PHY-TXSTART shall be disabled by the issuance of the PHY-TXEND.request primitive. Normal termination occurs after the transmission of the final bit of the last PSDU octet, calculated from the number supplied in the PHY preamble LENGTH and SERVICE fields using the equations specified in 16.2.3.6. The PPDU transmission shall be completed and the PHY entity shall enter the receive state (i.e., PHY-TXSTART shall be disabled). It is recommended that modulation

continue during power-down to prevent radiating a continuous wave carrier. Each PHY-TXEND.request primitive is acknowledged with a PHY-TXEND.confirm primitive from the PHY.

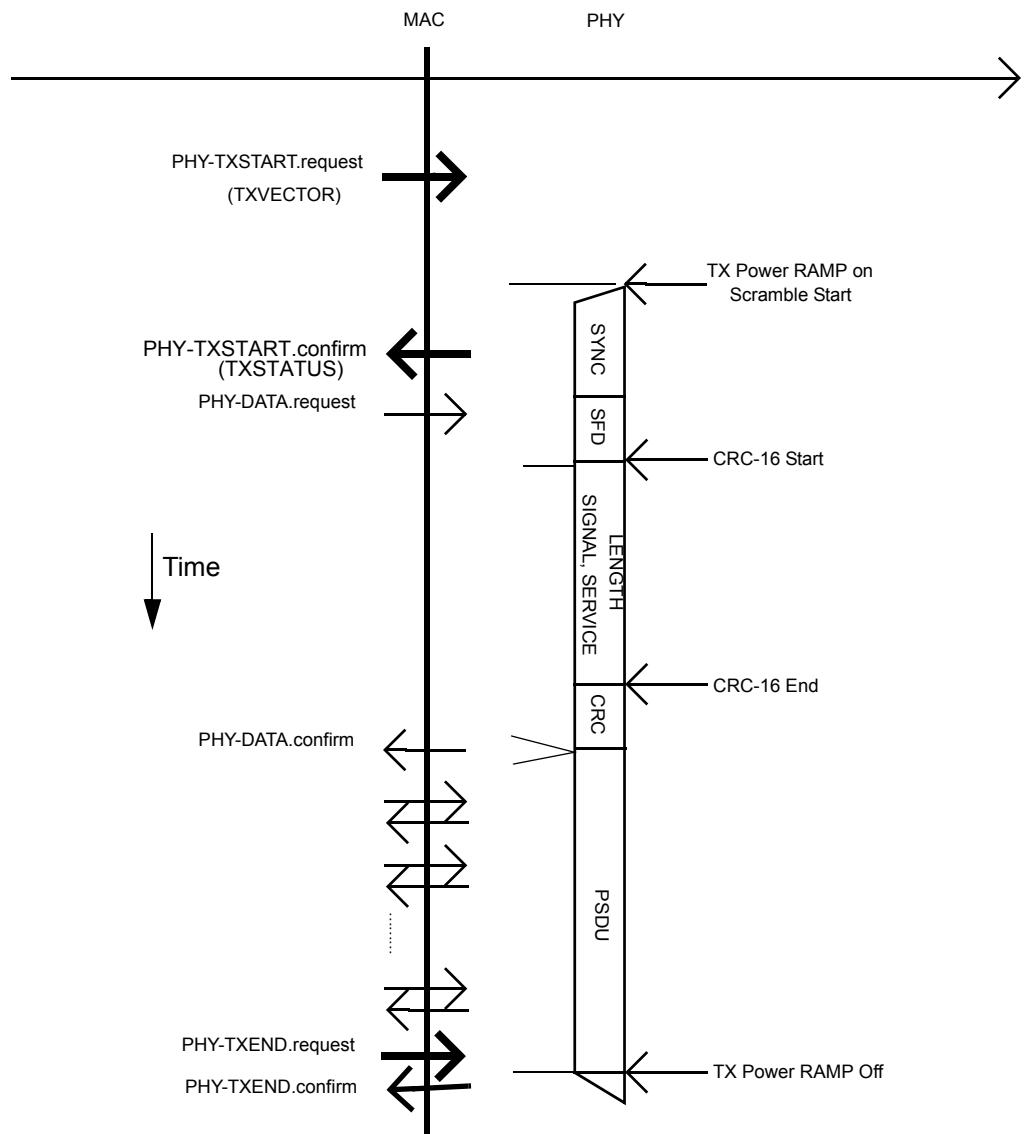

Figure 16-7—Transmit PHY

16.2.6 Receive PHY

The receive procedures for receivers configured to receive the mandatory and optional PHYs, rates, and modulations are described in this subclause. A receiver that supports this high rate extension of the standard is capable of receiving 5.5 Mb/s and 11 Mb/s, in addition to 1 Mb/s and 2 Mb/s. If the PHY implements the short preamble option, it shall detect both short and long preamble formats and indicate which type of preamble was received in the RXVECTOR. The receiver shall implement the CCA procedure as defined in 16.3.8.5. Upon receiving a PPDU, the receiver shall distinguish between a long and short

header format by the value of the SFD, as specified in 16.2.2. The receiver shall demodulate a long PHY header using BPSK at 1 Mb/s. The receiver shall demodulate a short PHY header using QPSK at 2 Mb/s. The receiver shall use the SIGNAL and SERVICE fields of the PHY header to determine the data rate and modulation of the PSDU.

The receive PHY is shown in Figure 16-8. In order to receive data, the PHY-TXSTART.request primitive shall be disabled so that the PHY entity is in the receive state. Further, through station management via the PLME, the PHY shall be set to the appropriate channel and the CCA method chosen. Other receive parameters, such as RSSI, RCPI, SQ, and indicated DATARATE, may be accessed via the PHY SAP.

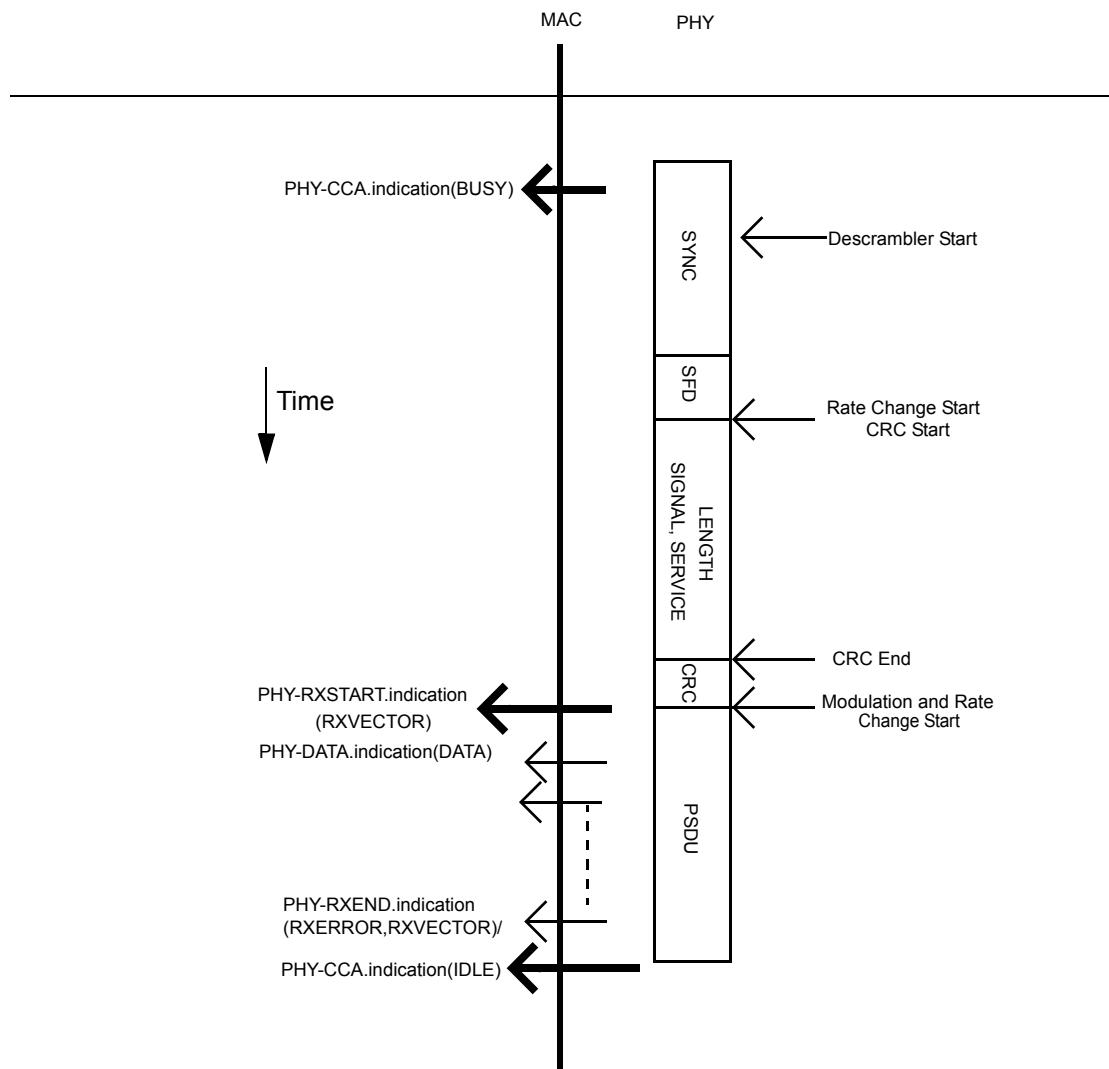

Figure 16-8—Receive PHY

Upon receiving the transmitted energy, according to the selected CCA mode a PHY-CCA.indication(BUSY) primitive shall be issued for ED and/or code lock prior to correct reception of the PHY header. The PHY measures the SQ, RSSI, and RCPI parameters and these are reported to the MAC in the RXVECTOR.

After a PHY-CCA.indication primitive is issued, the PHY entity shall begin searching for the SFD field. Once the SFD field is detected, CRC-16 processing shall be initiated and the PHY SIGNAL, SERVICE, and LENGTH fields shall be received. The CRC-16 FCS shall be processed. If the CRC-16 FCS check fails, the

PHY receiver shall return to the RX IDLE state, as depicted in Figure 16-9. Should the status of CCA return to the IDLE state during reception prior to completion of the full PPDU processing, the PHY receiver shall return to the RX IDLE state.

If the PHY header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued. The RXVECTOR associated with this primitive includes:

- a) The SIGNAL field
- b) The SERVICE field
- c) The PSDU length in octets (calculated from the LENGTH field in microseconds and the DATARATE in Mb/s, in accordance with the formula in 16.2.3.6)
- d) RXPREAMBLE_TYPE (which is an enumerated type taking on values SHORTPREAMBLE or LONGPREAMBLE)
- e) ANT_STATE (the antenna used for receive), RSSI, RCPI, and SQ

If dot11TimingMsmtActivated is true, the PHY shall do the following:

- Complete receiving the PHY header and verify the validity of the PHY Header.
- If the PHY header reception is successful (and the SIGNAL field is completely recognizable and supported), a PHY-RXSTART.indication(RXVECTOR) primitive shall be issued and RX_START_OF_FRAME_OFFSET parameter within the RXVECTOR shall be forwarded (see 16.3.5).

NOTE—The RX_START_OF_FRAME_OFFSET value is used as described in 6.3.57 in order to estimate when the start of the preamble for the incoming frame was detected on the medium at the receive antenna connector.

The received PSDU bits are assembled into octets and presented to the MAC using a series of PHY-DATA.indication(DATA) primitive exchanges. The rate and modulation change indicated in the SIGNAL field shall be initiated with the first symbol of the PSDU, as described in 16.2.5. The PHY proceeds with PSDU reception. After reception of the final bit of the last PSDU octet, as indicated by the PHY preamble LENGTH field, the receiver shall be returned to the RX IDLE state shown in Figure 16-9.

A PHY-RXEND.indication(NoError) primitive shall be issued. A PHY-CCA.indication(IDLE) primitive shall be issued following a change in PHYCS and/or PHYED according to the selected CCA method.

In the event that a change in PHYCS or PHYED would cause the status of CCA to return to the IDLE state before the complete reception of the PSDU, as indicated by the PHY LENGTH field, the error condition shall be reported to the MAC using a PHY-RXEND.indication(CarrierLost) primitive. The CCA of the HR/DSSS PHY shall indicate a busy medium for the intended duration of the transmitted PPDU.

If the PHY header is successful, but the indicated rate or modulation in the SIGNAL and SERVICE fields is not within the capabilities of the receiver, a PHY-RXSTART.indication primitive shall not be issued. The PHY shall indicate the error condition by issuing a PHY-RXEND.indication(UnsupportedRate) primitive. If the PHY header is invalid, a PHY-RXSTART.indication primitive shall not be issued, and the PHY shall indicate the error condition using a PHY-RXEND.indication(FormatViolation) primitive. Also, in both cases, the CCA of the HR/DSSS PHY shall indicate a busy medium for the intended duration of the transmitted PSDU, as indicated by the LENGTH field. The intended duration is indicated by the LENGTH field ($\text{LENGTH} \times 1 \mu\text{s}$).

A typical state machine implementation of the receive PHY is shown in Figure 16-9.

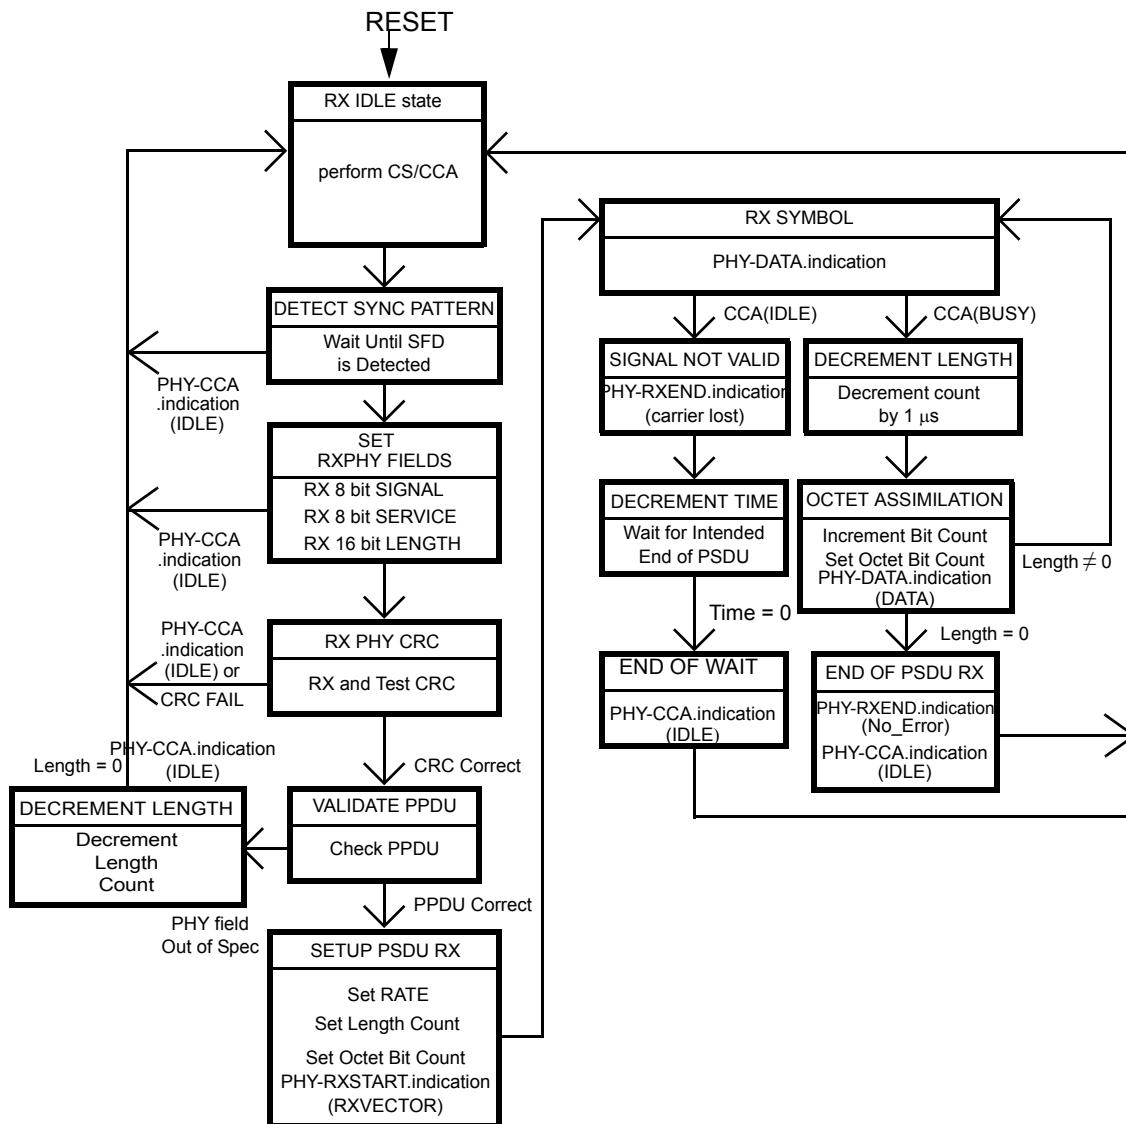

Figure 16-9—PHY receive state machine

16.3 HR/DSSS PLME

16.3.1 PLME SAP sublayer management primitives

Table 16-3 lists the MIB attributes that may be accessed by the PHY entities and intralayer or higher level LMEs. These attributes are accessed via the PLME-GET, PLME-SET, and PLME-RESET primitives defined in Clause 6.

16.3.2 HR/DSSS PHY MIB

All HR/DSSS PHY MIB attributes are defined in Annex C, with specific values defined in Table 16-3.

Table 16-3—MIB attribute default values/ranges

| Managed object | Default value/range | Operational semantics |
|---|-------------------------------------|------------------------------|
| dot11PhyOperationTable | | |

| NOTE—The column titled “Operational semantics” contains two types: static and dynamic. Static MIB attributes are fixed and cannot be modified for a given PHY implementation. Dynamic MIB attributes can be modified by some management entities. | | |

16.3.3 HR/DSSS PHY

The static HR/DSSS PHY characteristics, provided through the PLME-CHARACTERISTICS service primitive, are shown in Table 16-4. The definitions of these characteristics are in 6.5.4.

Table 16-4—HR/DSSS PHY characteristics

| Characteristic | Value |
|---------------------|--|
| aSlotTime | If dot11OperatingClassesRequired is false, 20 µs If dot11OperatingClassesRequired is true, 20 µs plus any coverage-class-dependent aAirPropagationTime (see Table 9-79) |
| aSIFSTime | 10 µs |
| aCCATime | Implementation dependent, see 10.3.7. |
| aRxPHYStartDelay | 192 µs for long preamble and 96 µs for short preamble |
| aRxTxTurnaroundTime | Implementation dependent, see 10.3.7. |
| aTxPHYDelay | Implementation dependent, see 10.3.7. |
| aRxPHYDelay | Implementation dependent, see 10.3.7. |
| aRxTxSwitchTime | Implementation dependent, see 10.3.7. |
| aTxRampOnTime | Implementation dependent, see 10.3.7. |
| aAirPropagationTime | As indicated by the coverage class (see 10.21.5). |
| aMACProcessingDelay | Implementation dependent, see 10.3.7. |
| aPreambleLength | 72 µs |
| aPHYHeaderLength | 24 µs |
| aPSDUMaxLength | $2^{12} - 1$ octets |
| aCWmin | 31 |
| aCWmax | 1023 |

16.3.4 HR/DSSS TXTIME calculation

The value of the TXTIME parameter returned by the PLME-TXTIME.confirm primitive shall be calculated according to the following equation:

$$\text{TXTIME} = \text{PreambleLength} + \text{PHYHeaderTime} + \left\lceil \frac{\text{LENGTH} \times 8}{\text{DATARATE}} \right\rceil$$

where

- LENGTH and DATARATE are values from the TXVECTOR parameter of the corresponding PLME-TXTIME.request primitive
- LENGTH is in units of octets
- DATARATE is in units of Mb/s
- The value of PreambleLength is 144 µs if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 72 µs if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”

The value of PHYHeaderTime is 48 μ s if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “LONGPREAMBLE,” or 24 μ s if the TXPREAMBLE_TYPE value from the TXVECTOR parameter indicates “SHORTPREAMBLE”

16.3.5 Vector descriptions

Several service primitives include a parameter vector. These vectors are a list of parameters as described in Table 16-5. DATARATE and LENGTH are described in 8.3.4.4. The remaining parameters are considered to be management parameters and are specific to this PHY.

Table 16-5—Parameter vectors

| Parameter | Associated vector | Value |
|-----------------------------|--------------------|--|
| DATARATE | RXVECTOR, TXVECTOR | The rate used to transmit the PSDU in Mb/s. |
| LENGTH | RXVECTOR, TXVECTOR | The length of the PSDU in octets. |
| PREAMBLE_TYPE | RXVECTOR, TXVECTOR | The preamble used for the transmission of this PPDU. This is an enumerated type that takes the value SHORTPREAMBLE or LONGPREAMBLE. |
| ANT_STATE | RXVECTOR | 1–256 |
| TX_ANTENNA | TXVECTOR | Selects which of the available antennas should be used for transmit, in the range 1 to 256. |
| RSSI | RXVECTOR | 0–8 bits of RSSI |
| RCPI (see NOTE) | RXVECTOR | 0–255 |
| SQ | RXVECTOR | 0–8 bits of SQ |
| TIME_OF_DEPARTURE_REQUESTED | TXVECTOR | false, true. When true, the MAC entity requests that the PHY entity measures and reports time of departure parameters corresponding to the time when the first frame energy is sent by the transmitting port; when false, the MAC entity requests that the PHY entity neither measures nor reports time of departure parameters. |
| TIME_OF_DEPARTURE | TXSTATUS | 0 to $2^{32}-1$. The time when the first frame energy is sent by the transmitting port, measured by the local PHY entity, in units equal to 1/TIME_OF_DEPARTURE_ClockRate. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request. |
| TIME_OF_DEPARTURE_ClockRate | TXSTATUS | 0 to $2^{16}-1$. The clock rate, in units of MHz, is used to generate the TIME_OF_DEPARTURE value. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request. |
| TX_START_OF_FRAME_OFFSET | TXSTATUS | 0 to $2^{32}-1$. An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the frame was transmitted at the transmit antenna connector to the point in time at which this primitive is issued to the MAC. |

Table 16-5—Parameter vectors (continued)

| Parameter | Associated vector | Value |
|--|-------------------|--|
| RX_START_OF_FRAME_OFFSET | RXVECTOR | 0 to $2^{32} - 1$. An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the incoming frame arrived at the receive antenna connector to the point in time at which this primitive is issued to the MAC. |
| NOTE—RCPI is present only when dot11RadioMeasurementActivated is true. | | |

16.3.6 PHY operating specifications, general

16.3.6.1 General

General specifications for the HR/DSSS PHY sublayer are provided in 16.3.6.2 to 16.3.6.11. These specifications apply to both the receive and transmit functions and general operation of a HR/DSSS PHY.

WLANs implemented in accordance with this standard are subject to equipment certification and operation requirements established by regional and national regulatory administrations. The PHY specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision, or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PHY specification. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the following regulatory sources for further information. Operation in countries within defined regulatory domains may be subject to additional regulations.

16.3.6.2 Operating frequency range

The HR/DSSS PHY shall operate in the 2.4–2.4835 GHz frequency range, as allocated by regulatory bodies in the China, United States, Europe, and Japan, or in the 2.471–2.497 GHz frequency range, as allocated by regulatory authority in Japan.

16.3.6.3 Channel Numbering of operating channels

When dot11OperatingClassesRequired is true, channel numbering shall be as specified in 17.3.8.4.2 and channelization shall be as specified in 17.3.8.4.3. When dot11OperatingClassesDefined is false or not defined, the channel center frequencies and CHNL_ID numbers shall be as shown in Table 16-6.

Table 16-6—HR/DSSS PHY frequency channel plan

| CHNL_ID | Frequency (MHz) |
|---------|-----------------|
| 1 | 2412 |
| 2 | 2417 |
| 3 | 2422 |
| 4 | 2427 |
| 5 | 2432 |
| 6 | 2437 |
| 7 | 2442 |

Table 16-6—HR/DSSS PHY frequency channel plan (continued)

| CHNL_ID | Frequency (MHz) |
|---------|-----------------|
| 8 | 2447 |
| 9 | 2452 |
| 10 | 2457 |
| 11 | 2462 |
| 12 | 2467 |
| 13 | 2472 |
| 14 | 2484 |

In a multiple cell network topology, overlapping and/or adjacent cells using different channels can operate simultaneously without interference if the distance between the center frequencies is at least 25 MHz. Channel 14 shall be designated specifically for operation in Japan.

16.3.6.4 Modulation and channel data rates

Four modulation formats and data rates are specified for the HR/DSSS PHY. The basic access rate shall be based on 1 Mb/s DBPSK modulation. The enhanced access rate shall be based on 2 Mb/s DQPSK. The extended direct sequence specification defines two additional data rates. The HR/DSSS access rates shall be based on the CCK modulation scheme for 5.5 Mb/s and 11 Mb/s.

16.3.6.5 Spreading sequence and modulation for 1 Mb/s and 2 Mb/s

The following 11-chip Barker sequence shall be used as the PN code sequence for the 1 Mb/s and 2 Mb/s modulation:

$$+1, -1, +1, +1, -1, +1, +1, +1, -1, -1, -1$$

The leftmost chip shall be output first in time. The first chip shall be aligned at the start of a transmitted symbol. The symbol duration shall be exactly 11 chips long.

The DBPSK encoder for the basic access rate is specified in Table 16-7. The DQPSK encoder is specified in Table 16-8. (In these tables, $+j\omega$ shall be defined as counterclockwise rotation.)

Table 16-7—1 Mb/s DBPSK encoding table

| Bit input | Phase change ($+j\omega$) |
|-----------|-----------------------------|
| 0 | 0 |
| 1 | π |

Table 16-8—2 Mb/s DQPSK encoding table

| Dabit pattern (d0,d1) (d0 is first in time) | Phase change (+jω) |
|--|--------------------|
| 00 | 0 |
| 01 | π/2 |
| 11 | π |
| 10 | 3π/2 (-π/2) |

16.3.6.6 Spreading sequences and modulation for CCK modulation at 5.5 Mb/s and 11 Mb/s

16.3.6.6.1 General

For the CCK modulation modes, the spreading code length is 8 and is based on complementary codes. The chipping rate is 11 Mchip/s. The symbol duration shall be exactly 8 complex chips long.

The following formula shall be used to derive the CCK codewords that shall be used for spreading both 5.5 Mb/s and 11 Mb/s

$$C = \{ e^{j(\varphi_1 + \varphi_2 + \varphi_3 + \varphi_4)}, e^{j(\varphi_1 + \varphi_3 + \varphi_4)}, e^{j(\varphi_1 + \varphi_2 + \varphi_4)}, \\ -e^{j(\varphi_1 + \varphi_4)}, e^{j(\varphi_1 + \varphi_2 + \varphi_3)}, e^{j(\varphi_1 + \varphi_3)}, -e^{j(\varphi_1 + \varphi_2)}, e^{j\varphi_1} \} \quad (16-1)$$

where C is the codeword

$$C = \{c_0 \text{ to } c_7\}$$

The terms φ_1 , φ_2 , φ_3 , and φ_4 are defined in 16.3.6.6.3 for 5.5 Mb/s and 16.3.6.6.4 for 11 Mb/s.

This formula creates 8 complex chips (c_0 to c_7), where c_0 is transmitted first in time.

This is a form of the generalized Hadamard transform encoding, where φ_1 is added to all code chips, φ_2 is added to all odd code chips, φ_3 is added to all odd pairs of code chips, and φ_4 is added to all odd groups of four code chips.

The term φ_1 modifies the phase of all code chips of the sequence and shall be DQPSK encoded for 5.5 Mb/s and 11 Mb/s. This shall take the form of rotating the whole symbol by the appropriate amount relative to the phase of the preceding symbol. Note that the chip c_7 of the symbol defined above is the chip that indicates the symbol's phase and is transmitted last.

16.3.6.6.2 Cover code for CCK

The fourth and seventh chips are rotated 180° by a cover sequence to optimize the sequence correlation properties and minimize dc offsets in the codes. This explains the minus sign on the fourth and seventh terms in Equation (16-1).

16.3.6.6.3 CCK 5.5 Mb/s modulation

At 5.5 Mb/s, 4 bits (d0 to d3; d0 first in time) are transmitted per symbol.

The data bits d0 and d1 encode φ_1 based on DQPSK. The DQPSK encoder is specified in Table 16-8. (In the table, $+j\omega$ shall be defined as counterclockwise rotation.) The phase change for φ_1 is relative to the phase φ_1 of the preceding symbol. For the header to PSDU transition, the phase change for φ_1 is relative to the phase

of the preceding DQPSK (2 Mb/s) symbol. That is, the phase of the last symbol of the CRC-16 is the reference phase for the first symbol generated from the PSDU octets. (See the definition in 16.3.6.5 for the reference phase of this Barker coded symbol.) A “+1” chip in the Barker code shall represent the same carrier phase as a “+1” chip in the CCK code.

All odd-numbered symbols generated from the PSDU octets shall be given an extra 180° (π) rotation, in addition to the standard DQPSK modulation as shown in Table 16-9. The symbols of the PSDU shall be numbered starting with 0 for the first symbol, for the purposes of determining odd and even symbols. That is, the PSDU transmission starts on an even-numbered symbol.

Table 16-9—DQPSK encoding table

| Dibit pattern (d0, d1) (d0 is first in time) | Even symbols phase change (+j ω) | Odd symbols phase change (+j ω) |
|---|---|--|
| 00 | 0 | π |
| 01 | $\pi/2$ | $3\pi/2$ ($-\pi/2$) |
| 11 | π | 0 |
| 10 | $3\pi/2$ ($-\pi/2$) | $\pi/2$ |

The data dibits d2 and d3 CCK encode the basic symbol, as specified in Table 16-10. This table is derived from the formula above by setting $\varphi_2 = (d2 \times \pi) + \pi/2$, $\varphi_3 = 0$, and $\varphi_4 = d3 \times \pi$. In this table, d2 and d3 are in the order shown, and the complex chips are shown c0 to c7 (left to right), with c0 transmitted first in time.

Table 16-10—5.5 Mb/s CCK encoding table

| d2, d3 | c1 | c2 | c3 | c4 | c5 | c6 | c7 | c8 |
|--------|-----|----|-----|----|-----|----|-----|----|
| 00 | 1j | 1 | 1j | -1 | 1j | 1 | -1j | 1 |
| 01 | -1j | -1 | -1j | 1 | 1j | 1 | -1j | 1 |
| 10 | -1j | 1 | -1j | -1 | -1j | 1 | 1j | 1 |
| 11 | 1j | -1 | 1j | 1 | -1j | 1 | 1j | 1 |

16.3.6.6.4 CCK 11 Mb/s modulation

At 11 Mb/s, 8 bits (d0 to d7; d0 first in time) are transmitted per symbol.

The first dibit (d0, d1) encodes φ_1 based on DQPSK. The DQPSK encoder is specified in Table 16-8. The phase change for φ_1 is relative to the phase φ_1 of the preceding symbol. In the case of header to PSDU transition, the phase change for φ_1 is relative to the phase of the preceding DQPSK symbol. All odd-numbered symbols of the PSDU are given an extra 180° (π) rotation, in accordance with the DQPSK modulation shown in Table 16-8. Symbol numbering starts with 0 for the first symbol of the PSDU.

The data dibits (d2, d3), (d4, d5), and (d6, d7) encode φ_2 , φ_3 , and φ_4 , respectively, based on QPSK as specified in Table 16-11. Note that this table is binary (not Gray) coded.

Table 16-11—QPSK encoding table

| Dibit pattern [d _i , d _(i+1)] (d _i is first in time) | Phase |
|---|-----------------------|
| 00 | 0 |
| 01 | $\pi/2$ |
| 10 | π |
| 11 | $3\pi/2$ ($-\pi/2$) |

16.3.6.7 Transmit and receive in-band and out-of-band spurious emissions

The HR/DSSS PHY shall comply with in-band and out-of-band spurious emissions as set by the appropriate regulatory bodies.

16.3.6.8 TX-to-RX turnaround time

The TX-to-RX turnaround time shall be less than 10 μ s, including the power-down ramp specified in 16.3.7.7.

The TX-to-RX turnaround time shall be measured on the WM from the trailing edge of the last transmitted symbol to the valid CCA detection of the incoming signal. The CCA should occur within 25 μ s (10 μ s for turnaround time, plus 15 μ s for energy detect), or by the next slot boundary occurring after the 25 μ s has elapsed (see 16.3.8.5). A receiver input signal 3 dB above the ED threshold described in 16.3.8.5 shall be present at the receiver.

16.3.6.9 RX-to-TX turnaround time

The RX-to-TX turnaround time shall be measured at the MAC/PHY interface using the PHY-TXSTART.request primitive, and shall be 5 μ s. This includes the transmit power-on ramp described in 16.3.7.7.

16.3.6.10 Slot time

The value of the slot time is found in Table 16-4.

16.3.6.11 Transmit and receive impedance at the antenna connector

The impedance at the transmit and receive antenna connector(s) shall be 50 Ω if the connector is exposed.

16.3.7 PHY transmit specifications

16.3.7.1 Introduction

The transmit functions and parameters associated with the PHY sublayer are described in 16.3.7.2 to 16.3.7.9.

16.3.7.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

16.3.7.3 Transmit power level control

Power control shall be provided for transmitted power greater than 100 mW. A maximum of four power levels may be provided. As a minimum, a radio capable of transmission greater than 100 mW shall be capable of switching power back to 100 mW or less.

16.3.7.4 Transmit spectrum mask

The transmitted spectral products shall be less than -30 dB_r (decibel relative to the SINx/x peak) for

$$f_c - 22 \text{ MHz} < f < f_c - 11 \text{ MHz} \text{ and}$$

$$f_c + 11 \text{ MHz} < f < f_c + 22 \text{ MHz}$$

and shall be less than -50 dB_r for

$$f < f_c - 22 \text{ MHz} \text{ and}$$

$$f > f_c + 22 \text{ MHz}$$

where

f_c is the channel center frequency

The transmit spectral mask is shown in Figure 16-10. The measurements shall be made using a 100 kHz resolution bandwidth and a 100 kHz video bandwidth.

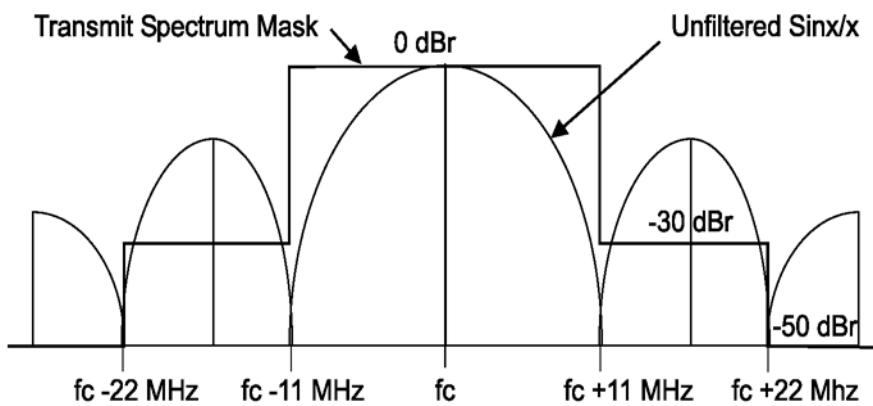

Figure 16-10—Transmit spectrum mask

16.3.7.5 Transmit center frequency tolerance

The transmitted center frequency tolerance shall be ± 25 ppm maximum.

16.3.7.6 Chip clock frequency tolerance

The PN code chip clock frequency tolerance shall be ± 25 ppm maximum. It is highly recommended that the chip clock and the transmit frequency be locked (coupled) for optimum demodulation performance. If these clocks are locked, it is recommended that bit 2 of the SERVICE field be set to 1, as indicated in 16.2.3.5.

16.3.7.7 Transmit power-on and power-down ramp

The transmit power-on ramp for 10% to 90% of maximum power shall be no greater than 2 μ s. The transmit power-on ramp is shown in Figure 16-11.

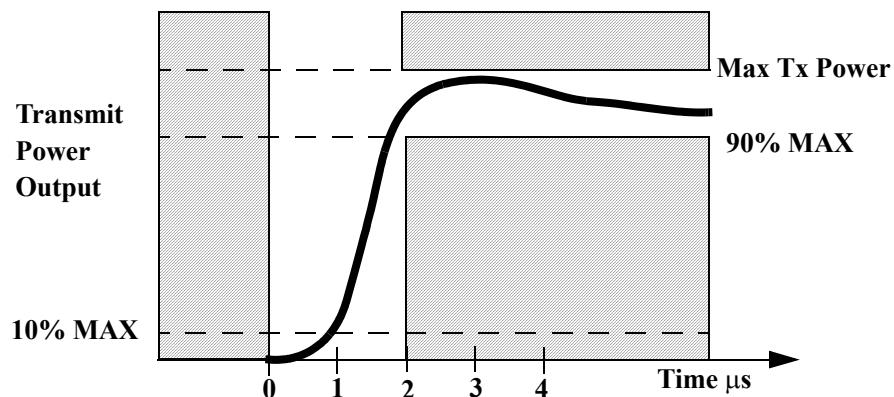

Figure 16-11—Transmit power-on ramp

The transmit power-down ramp for 90% to 10% maximum power shall be no greater than 2 μ s. The transmit power-down ramp is shown in Figure 16-12.

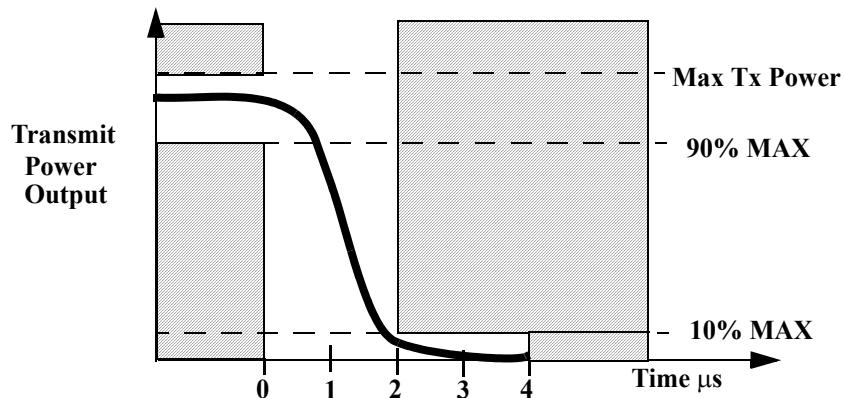

Figure 16-12—Transmit power-down ramp

The transmit power ramps shall be constructed such that the HR/DSSS PHY emissions comply with spurious frequency product specification defined in 16.3.6.7.

16.3.7.8 RF carrier suppression

The RF carrier suppression, measured at the channel center frequency, shall be at least 15 dB below the peak $\sin(x)/x$ power spectrum. The RF carrier suppression shall be measured while transmitting a repetitive 01 data sequence with the scrambler disabled using DQPSK modulation. A 100 kHz resolution bandwidth shall be used to perform this measurement.

16.3.7.9 Transmit modulation accuracy

The transmit modulation accuracy requirement for the HR/DSSS PHY shall be based on the difference between the actual transmitted waveform and the ideal signal waveform. Modulation accuracy shall be determined by measuring the peak vector error magnitude during each chip period. Worst-case vector error magnitude shall not exceed 0.35 for the normalized sampled chip data. The ideal complex I and Q constellation points associated with DQPSK modulation, (0.707, 0.707), (0.707, -0.707), (-0.707, 0.707), (-0.707, -0.707), shall be used as the reference. These measurements shall be from baseband I and Q sampled data after recovery through a reference receiver system.

Figure 16-13 illustrates the ideal DQPSK constellation points and range of worst-case error specified for modulation accuracy.

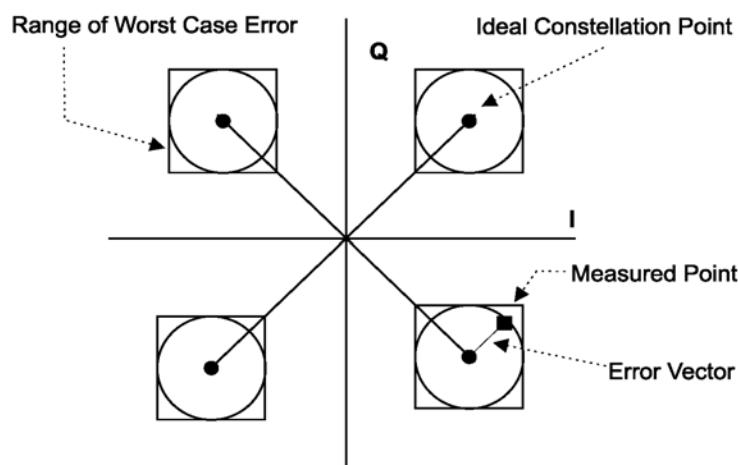

Figure 16-13—Modulation accuracy measurement example

Error vector measurement requires a reference receiver capable of carrier lock. All measurements shall be made under carrier lock conditions. The distortion induced in the constellation by the reference receiver shall be calibrated and measured. The test data error vectors described below shall be corrected to compensate for the reference receiver distortion.

The IEEE Std 802.11-compatible radio shall provide an exposed TX chip clock, which shall be used to sample the I and Q outputs of the reference receiver.

The measurement shall be made under the conditions of continuous DQPSK transmission using scrambled all 1s.

The eye pattern of the I channel shall be used to determine the I and Q sampling point. The chip clock provided by the vendor radio shall be time delayed, such that the samples fall at a 1/2 chip period offset from the mean of the zero crossing positions of the eye (see Figure 16-14). This is the ideal center of the eye and might not be the point of maximum eye opening.

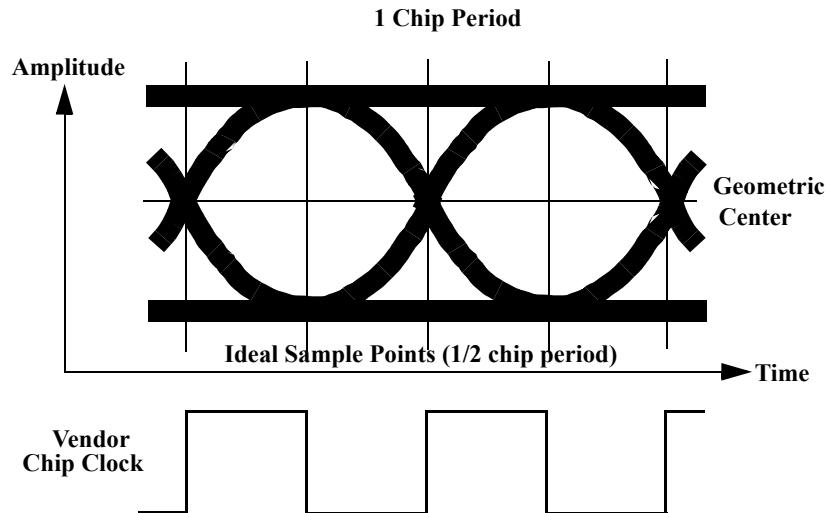

Figure 16-14—Chip clock alignment with baseband eye pattern

Using the aligned chip clock, 1000 samples of the I and Q baseband outputs from the reference receiver are captured. The vector error magnitudes shall be calculated as follows:

Calculate the dc offsets for I and Q samples

$$I_{\text{mean}} = \sum_{n=0}^{999} I(n) / 1000$$

$$Q_{\text{mean}} = \sum_{n=0}^{999} Q(n) / 1000$$

Calculate the dc corrected *I* and *Q* samples for all *n* = 1000 sample pairs

$$I_{dc}(n) = I(n) - I_{\text{mean}}$$

$$Q_{dc}(n) = Q(n) - Q_{\text{mean}}$$

Calculate the average magnitude of *I* and *Q* samples

$$I_{\text{mag}} = \sum_{n=0}^{999} |I_{dc}(n)| / 1000$$

$$Q_{\text{mag}} = \sum_{n=0}^{999} |Q_{dc}(n)| / 1000$$

Calculate the normalized error vector magnitude for the $I_{dc}(n)/Q_{dc}(n)$ pairs

$$V_{err}(n) = [\{ |I_{dc}(n)| - I_{mag} \}^2 + \{ |Q_{dc}(n)| - Q_{mag} \}^2]^{\frac{1}{2}} - V_{correction}$$

where

| | |
|--|---|
| the average power of the constellation | is 1 |
| $V_{correction}$ | is the error induced by the reference receiver system |

For all $n = 1000$ samples, the following condition shall be met:

$$V_{err}(n) < 0.35$$

16.3.7.10 Time of Departure accuracy

The Time of Departure accuracy test evaluates TIME_OF_DEPARTURE against aTxPHYTxStartRMS and aTxPHYTxStartRMS against TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH as defined in Annex P with the following test parameters:

- MULTICHANNEL_SAMPLING_RATE is $22 \times 10^6 \left(1 + \left\lceil \frac{f_H - f_L}{22 \text{ MHz}} \right\rceil\right)$ sample/s
 where
 - f_H is the nominal center frequency in Hz of the highest channel in the channel set
 - f_L is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across $f_H - f_L \geq 50 \text{ MHz}$
- FIRST_TRANSITION_FIELD is the SYNC field.
- SECOND_TRANSITION_FIELD is the SFD field.
- TRAINING_FIELD is the concatenation of the appropriate short or long SYNC and SFD fields, using a chip pulse which should approximate a rectangular pulse of duration 1/11 MHz convolved with a brick-wall low pass filter of bandwidth 11 MHz.
- TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH is 80 ns.

NOTE—The indicated chip pulse applies to the time of departure accuracy test equipment, and not the transmitter or receiver.

16.3.8 PHY receiver specifications

16.3.8.1 Introduction

The receive functions and parameters associated with the PHY sublayer are described in 16.3.8.2 to 16.3.8.5.

16.3.8.2 Receiver minimum input level sensitivity

The FER shall be less than 8×10^{-2} at a PSDU length of 1024 octets for an input level of -76 dBm measured at the antenna connector. This FER shall be specified for 11 Mb/s CCK modulation. The test for the minimum input level sensitivity shall be conducted with the ED threshold set less than or equal to -76 dBm .

16.3.8.3 Receiver maximum input level

The receiver shall provide a maximum FER of 8×10^{-2} at a PSDU length of 1024 octets for a maximum input level of -10 dBm measured at the antenna. This FER shall be specified for 11 Mb/s CCK modulation.

16.3.8.4 Receiver adjacent channel rejection

Adjacent channel rejection is defined between any two channels with ≥ 25 MHz separation in each channel group, as defined in 16.3.6.3.

The adjacent channel rejection shall be greater than or equal to than 35 dB, with an FER of 8×10^{-2} using 11 Mb/s CCK modulation described in 16.3.6.4 and a PSDU length of 1024 octets.

The adjacent channel rejection shall be measured using the following method.

Input an 11 Mb/s CCK modulated signal at a level 6 dB greater than specified in 16.3.8.2. In an adjacent channel (≥ 25 MHz separation as defined by the channel numbering), input a signal modulated in a similar fashion, which adheres to the transmit mask specified in 16.3.7.4, to a level 41 dB above the level specified in 16.3.8.2. The adjacent channel signal shall be derived from a separate signal source. It shall not be a frequency shifted version of the reference channel. Under these conditions, the FER shall be less than or equal to 8×10^{-2} .

16.3.8.5 CCA

The HR/DSSS PHY shall provide the capability to perform CCA according to both:

A — At least one of the following options:

- *CCA Mode 1*: Energy above threshold. CCA shall report a busy medium upon detecting any energy above the ED threshold.
- *CCA Mode 4*: CS with timer. CCA shall start a timer whose duration is 3.65 ms and report a busy medium only upon the detection of a HR/DSSS PHY signal. CCA shall report an IDLE medium after the timer expires and no HR/DSSS PHY signal is detected. The 3.65 ms timeout is the duration of the longest possible 5.5 Mb/s PSDU.
- *CCA Mode 5*: A combination of CS and energy above threshold. CCA shall report busy at least while a HR/DSSS PPDU is being received with energy above the ED threshold at the antenna.

and

B — *CCA Mode 6*: CCA shall report a busy medium upon detection of any energy above -62 dBm.

A busy channel shall be indicated by issuing a PHY-CCA.indication(BUSY) primitive. A clear channel shall be indicated by issuing a PHY-CCA.indication(IDLE) primitive.

dot11HRCCAModeSupported shall indicate the appropriate operation modes. The PHY shall be configured through dot11CurrentCCAMode.

The CCA shall indicate a clear channel if there is no energy detect or CS. The CCA parameters are subject to the following criteria:

- a) If a valid HR/DSSS signal is detected during its preamble within the CCA window, the ED threshold shall be less than or equal to -76 dBm for TX power > 100 mW; -73 dBm for 50 mW $<$ TX power ≤ 100 mW; and -70 dBm for TX power ≤ 50 mW.

- b) With a valid signal (according to the CCA mode of operation) present at the receiver antenna within 5 μ s of the start of a MAC slot boundary, the PHY-CCA.indication(BUSY) primitive shall be generated before the end of the slot time. Refer to Figure 10-19 (in 10.3.7) and Figure 10-26 for a definition of slot boundary.
- c) In the event that a correct PHY header is received, the HR/DSSS PHY shall not generate a PHY-CCA.indication (IDLE) primitive until the end of the PPDU as determined by TXTIME in 16.3.4. Upon reception of a correct PHY header, the timer of CCA Mode 4 shall be overridden by this requirement.

Compliance to the HR/DSSS PHY CCA shall be demonstrated by applying an equivalent HR/DSSS signal above the appropriate ED threshold (item a) so that all conditions described in item b and item c are demonstrated.

16.3.8.6 Received Channel Power Indicator Measurement

The RCPI indicator is a measure of the received RF power in the selected channel for a received frame. This parameter shall be a measure by the PHY of the received RF power in the channel measured over the entire received frame or by other equivalent means that meet the specified accuracy.

The RCPI encoding is defined in 9.4.2.38.

RCPI shall equal the received RF power within an accuracy of ± 5 dB (95% confidence interval) within the specified dynamic range of the receiver. The received RF power shall be determined assuming a receiver noise equivalent bandwidth equal to the channel bandwidth multiplied by 1.1.

17. Orthogonal frequency division multiplexing (OFDM) PHY specification

17.1 Introduction

17.1.1 General

This clause specifies the PHY entity for an orthogonal frequency division multiplexing (OFDM) system. The OFDM system provides a WLAN with data payload communication capabilities of 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s. The support of transmitting and receiving at data rates of 6, 12, and 24 Mb/s is mandatory. The system uses 52 subcarriers that are modulated using binary or quadrature phase shift keying (BPSK or QPSK) or using 16- or 64-quadrature amplitude modulation (16-QAM or 64-QAM). Forward error correction coding (convolutional coding) is used with a coding rate of 1/2, 2/3, or 3/4.

The OFDM system also provides a “half-clocked” operation using 10 MHz channel spacings with data communications capabilities of 3, 4.5, 6, 9, 12, 18, 24, and 27 Mb/s. The support of transmitting and receiving at data rates of 3, 6, and 12 Mb/s is mandatory when using 10 MHz channel spacing. The half-clocked operation doubles symbol times and clear channel assessment (CCA) times when using 10 MHz channel spacing. The regulatory requirements and information regarding use of this OFDM PHY are in Annex D and Annex E.

The OFDM system also provides a “quarter-clocked” operation using 5 MHz channel spacing with data communication capabilities of 1.5, 2.25, 3, 4.5, 6, 9, 12, and 13.5 Mb/s. The support of transmitting and receiving at data rates of 1.5, 3, and 6 Mb/s is mandatory when using 5 MHz channel spacing. The quarter-clocked operation quadruples symbol times and CCA times when using 5 MHz channel spacing. The regulatory requirements and information regarding use of this OFDM PHY are in Annex D and Annex E.

17.1.2 Scope

Subclause 17.1 describes the PHY services provided to the IEEE 802.11 WLAN MAC by the OFDM PHY. The OFDM PHY consists of the following protocol functions:

- a) A function that defines a method of mapping the IEEE 802.11 PSDUs into a framing format suitable for sending and receiving user data and management information between two or more STAs.
- b) A function that defines the characteristics and method of transmitting and receiving data through a WM between two or more STAs, each using the OFDM system.

17.1.3 OFDM PHY functions

17.1.3.1 General

The OFDM PHY architecture is depicted in the reference model shown in Figure 4-19 (in 4.9). The OFDM PHY contains two functional entities: the PHY function and the layer management function. Each of these functions is described in detail in 17.3 and 17.4.

The OFDM PHY service is provided to the MAC through the PHY service primitives described in Clause 8.

17.1.3.2 PLME

The PLME performs management of the local PHY functions in conjunction with the MLME.

17.1.3.3 Service specification method

The models represented by figures and state diagrams are intended to be illustrations of the functions provided. It is important to distinguish between a model and a real implementation. The models are optimized for simplicity and clarity of presentation, but do not necessarily reflect any particular implementation.

The service of a layer or sublayer is the set of capabilities that it offers to a user in the next higher layer (or sublayer). Abstract services are specified here by describing the service primitives and parameters that characterize each service. This definition is independent of any particular implementation.

17.2 OFDM PHY specific service parameter list

17.2.1 Introduction

The architecture of the IEEE 802.11 MAC is intended to be PHY independent. Some PHY implementations require medium management state machines running in the MAC sublayer in order to meet certain PHY requirements. These PHY-dependent MAC state machines reside in a sublayer defined as the MLME. In certain PHY implementations, the MLME may need to interact with the PLME as part of the normal PHY SAP primitives. These interactions are defined by the PLME parameter list currently defined in the PHY service primitives as TXVECTOR and RXVECTOR. The list of these parameters, and the values they may represent, are defined in the specific PHY specifications for each PHY. Subclause 17.2 addresses the TXVECTOR and RXVECTOR for the OFDM PHY.

17.2.2 TXVECTOR parameters

17.2.2.1 General

The parameters in Table 17-1 are defined as part of the TXVECTOR parameter list in the PHY-TXSTART.request primitive.

Table 17-1—TXVECTOR parameters

| Parameter | Associated primitive | Value |
|--------------------|--------------------------------|--|
| LENGTH | PHY-TXSTART.request (TXVECTOR) | 1–4095 |
| DATARATE | PHY-TXSTART.request (TXVECTOR) | 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s for 20 MHz channel spacing (Support of 6, 12, and 24 Mb/s data rates is mandatory.) 3, 4.5, 6, 9, 12, 18, 24, and 27 Mb/s for 10 MHz channel spacing (Support of 3, 6, and 12 Mb/s data rates is mandatory.) 1.5, 2.25, 3, 4.5, 6, 9, 12, and 13.5 Mb/s for 5 MHz channel spacing (Support of 1.5, 3, and 6 Mb/s data rates is mandatory.) |
| SERVICE | PHY-TXSTART.request (TXVECTOR) | Null |
| TXPWR_LEVEL_IN_DEX | PHY-TXSTART.request (TXVECTOR) | 1–8 |

Table 17-1—TXVECTOR parameters (continued)

| Parameter | Associated primitive | Value |
|-----------------------------|-------------------------------|--|
| TIME_OF_DEPARTURE_REQUESTED | PHY-TXSTART.request(TXVECTOR) | false, true. When true, the MAC entity requests that the PHY entity measures and reports time of departure parameters corresponding to the time when the first frame energy is sent by the transmitting port; when false, the MAC entity requests that the PHY entity neither measures nor reports time of departure parameters. |
| CH_BANDWIDTH_IN_NON_HT | PHY-TXSTART.request(TXVECTOR) | If present, CBW20, CBW40, CBW80, CBW160, or CBW80+80 |
| DYN_BANDWIDTH_IN_NON_HT | PHY-TXSTART.request(TXVECTOR) | If present, Static or Dynamic |

17.2.2.2 TXVECTOR LENGTH

The allowed values for the LENGTH parameter are in the range 1 to 4095. This parameter is used to indicate the number of octets in the MPDU which the MAC is currently requesting the PHY to transmit. This value is used by the PHY to determine the number of octet transfers that will occur between the MAC and the PHY after receiving a request to start the transmission.

17.2.2.3 TXVECTOR DATARATE

The DATARATE parameter describes the bit rate at which the PHY shall transmit the PSDU. Its value takes any of the rates defined in Table 17-1. Data rates of 6, 12, and 24 Mb/s shall be supported for 20 MHz channel spacing, data rates of 3, 6, and 12 Mb/s shall be supported for 10 MHz channel spacing, and data rates of 1.5, 3, and 6 Mb/s shall be supported for 5 MHz channel spacing; other rates may also be supported.

17.2.2.4 TXVECTOR SERVICE

The SERVICE parameter shall be null.

17.2.2.5 TXVECTOR TXPWR_LEVEL_INDEX

The allowed values for the TXPWR_LEVEL_INDEX parameter are in the range 1 to 8. This parameter is used to indicate which of the available TxPowerLevel attributes defined in the MIB shall be used for the current transmission.

17.2.2.6 TXVECTOR TIME_OF_DEPARTURE_REQUESTED

The allowed values are false or true. A parameter value of true indicates that the MAC sublayer is requesting that the PHY entity provides measurement of when the first frame energy is sent by the transmitting port and reporting within the PHY-TXSTART.confirm(TXSTATUS) primitive. A parameter value of false indicates that the MAC sublayer is requesting that the PHY entity not provide time of departure measurement nor reporting in the PHY-TXSTART.confirm(TXSTATUS) primitive.

17.2.2.7 TXVECTOR CH_BANDWIDTH_IN_NON_HT

If present, the allowed values for CH_BANDWIDTH_IN_NON_HT are CBW20, CBW40, CBW80, CBW160, and CBW80+80. If present, this parameter is used to modify the first 7 bits of the scrambling sequence to indicate the bandwidth of the non-HT duplicate PPDU.

NOTE—The CH_BANDWIDTH_IN_NON_HT parameter is not present when the frame is transmitted by a non-VHT STA. The CH_BANDWIDTH_IN_NON_HT parameter is not present when the frame is transmitted by a VHT STA to a non-VHT STA. See 10.7.11.

17.2.2.8 TXVECTOR DYN_BANDWIDTH_IN_NON_HT

If present, the allowed values for DYN_BANDWIDTH_IN_NON_HT are Static and Dynamic. If present, this parameter is used to modify the first 7 bits of the scrambling sequence to indicate if the transmitter is capable of Static or Dynamic bandwidth operation. If DYN_BANDWIDTH_IN_NON_HT is present, then CH_BANDWIDTH_IN_NON_HT is also present.

NOTE—The DYN_BANDWIDTH_IN_NON_HT parameter is not present when the frame is transmitted by a non-VHT STA. The DYN_BANDWIDTH_IN_NON_HT parameter is not present when the frame is transmitted by a VHT STA to a non-VHT STA. See 10.7.11.

17.2.3 RXVECTOR parameters

17.2.3.1 General

The parameters listed in Table 17-2 are defined as part of the RXVECTOR parameter list in the PHY-RXSTART.indication primitive.

Table 17-2—RXVECTOR parameters

| Parameter | Associated primitive | Value |
|-------------------------|--|--|
| LENGTH | PHY-RXSTART.indication | 1–4095 |
| RSSI | PHY-RXSTART.indication (RXVECTOR) | 0–RSSI maximum |
| DATARATE | PHY-RXSTART.request (RXVECTOR) | 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s for 20 MHz channel spacing (Support of 6, 12, and 24 Mb/s data rates is mandatory.) 3, 4.5, 6, 9, 12, 18, 24, and 27 Mb/s for 10 MHz channel spacing (Support of 3, 6, and 12 Mb/s data rates is mandatory.) 1.5, 2.25, 3, 4.5, 6, 9, 12, and 13.5 Mb/s for 5 MHz channel spacing (Support of 1.5, 3, and 6 Mb/s data rates is mandatory.) |
| SERVICE | PHY-RXSTART.request (RXVECTOR) | Null |
| RCPI (see NOTE) | PHY-RXSTART.indication (RXVECTOR) PHY-RXEND.indication (RXVECTOR) | 0–255 |
| ANT_STATE (see NOTE) | PHY-RXSTART.indication (RXVECTOR) PHY-RXEND.indication (RXVECTOR) | 0–255 |

Table 17-2—RXVECTOR parameters (continued)

| Parameter | Associated primitive | Value |
|--------------------------|-----------------------------------|--|
| RX_START_OF_FRAME_OFFSET | PHY-RXSTART.indication (RXVECTOR) | 0 to $2^{32} - 1$. An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the incoming frame arrived at the receive antenna connector to the point in time at which this primitive is issued to the MAC. |
| CH_BANDWIDTH_IN_NON_HT | PHY-RXSTART.request (RXVECTOR) | If present, CBW20, CBW40, CBW80, CBW160, or CBW80+80 |
| DYN_BANDWIDTH_IN_NON_HT | PHY-RXSTART.request (RXVECTOR) | If present, Static or Dynamic |

NOTE—Parameter is present only when dot11RadioMeasurementActivated is true.

17.2.3.2 RXVECTOR LENGTH

The allowed values for the LENGTH parameter are in the range 1–4095. This parameter is used to indicate the value contained in the LENGTH field which the PHY has received in the PHY header. The MAC and PHY use this value to determine the number of octet transfers that will occur between the two sublayers during the transfer of the received PSDU.

17.2.3.3 RXVECTOR RSSI

The allowed values for the RSSI parameter are in the range 0 to RSSI maximum. This parameter is a measure by the PHY of the energy observed at the antenna used to receive the current PPDU. RSSI shall be measured during the reception of the PHY preamble. RSSI is intended to be used in a relative manner, and it shall be a monotonically increasing function of the received power.

17.2.3.4 RXVECTOR DATARATE

DATARATE shall represent the data rate at which the current PPDU was received. The allowed values of the DATARATE are 6, 9, 12, 18, 24, 36, 48, or 54 Mb/s for 20 MHz channel spacing; 3, 4.5, 6, 9, 12, 18, 24, or 27 Mb/s for 10 MHz channel spacing; and 1.5, 2.25, 3, 4.5, 6, 9, 12, or 13.5 Mb/s for 5 MHz channel spacing.

17.2.3.5 RXVECTOR SERVICE

The SERVICE parameter shall be null.

17.2.3.6 RXVECTOR RCPI

The allowed values for the RCPI parameter are in the range 0 to 255, as defined in 17.3.10.7. This parameter is a measure by the PHY of the received channel power. RCPI indications of 8 bits are supported. RCPI shall be measured over the entire received frame or by other equivalent means that meet the specified accuracy.

17.2.3.7 RXVECTOR CH_BANDWIDTH_IN_NON_HT

If present, the allowed values for CH_BANDWIDTH_IN_NON_HT are CBW20, CBW40, CBW80, CBW160, and CBW80+80. If present and valid, this parameter indicates the bandwidth of the non-HT duplicate PPDU. This parameter is used by the MAC only when valid (see 10.3.2.7 and 10.7.6.6).

NOTE—The CH_BANDWIDTH_IN_NON_HT parameter is not present when the frame is received by a non-VHT STA (see 10.7.11).

17.2.3.8 RXVECTOR DYN_BANDWIDTH_IN_NON_HT

If present, the allowed values for DYN_BANDWIDTH_IN_NON_HT are Static and Dynamic. If present and valid, this parameter indicates whether the transmitter is capable of Static or Dynamic bandwidth operation. This parameter is used by the MAC only when valid (see 10.3.2.7 and 10.7.6.6). If DYN_BANDWIDTH_IN_NON_HT is present, then CH_BANDWIDTH_IN_NON_HT is also present.

NOTE—The DYN_BANDWIDTH_IN_NON_HT parameter is not present when the frame is received by a non-VHT STA (see 10.7.11).

17.2.4 TXSTATUS parameters

17.2.4.1 General

The parameters listed in Table 17-3 are defined as part of the TXSTATUS parameter list in the PHY-TXSTART.confirm primitive.

Table 17-3—TXSTATUS parameters

| Parameter | Associated primitive | Value |
|-----------------------------|--------------------------------|--|
| TIME_OF_DEPARTURE | PHY-TXSTART.confirm (TXSTATUS) | 0 to $2^{32}-1$. The locally measured time when the first frame energy is sent by the transmitting port, in units equal to 1/TIME_OF_DEPARTURE_ClockRate. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request. |
| TIME_OF_DEPARTURE_ClockRate | PHY-TXSTART.confirm (TXSTATUS) | 0 to $2^{16}-1$. The clock rate, in units of MHz, is used to generate the TIME_OF_DEPARTURE value. This parameter is present only if TIME_OF_DEPARTURE_REQUESTED is true in the corresponding request. |
| TX_START_OF_FRAME_OFFSET | PHY-TXSTART.confirm (TXSTATUS) | 0 to $2^{32}-1$. An estimate of the offset (in 10 ns units) from the point in time at which the start of the preamble corresponding to the frame was transmitted at the transmit antenna connector to the point in time at which this primitive is issued to the MAC. |

17.2.4.2 TXSTATUS TIME_OF_DEPARTURE

The allowed values for the TIME_OF_DEPARTURE parameter are integers in the range 0 to $2^{32}-1$. This parameter is used to indicate when the first frame energy is sent by the transmitting port in units equal to 1/TIME_OF_DEPARTURE_ClockRate. TIME_OF_DEPARTURE may be included in the transmitted frame in order for recipients on multiple channels to determine the time differences of air propagation times between transmitter and recipients and hence to compute the location of the transmitter.

17.2.4.3 TXSTATUS TIME_OF_DEPARTURE_ClockRate

TIME_OF_DEPARTURE_ClockRate indicates the clock rate used for TIME_OF_DEPARTURE.

17.3 OFDM PHY

17.3.1 Introduction

Subclause 17.3 provides a convergence procedure in which PSDUs are converted to and from PPDUs. During transmission, the PSDU shall be provided with a PHY preamble and header to create the PPDU. At the receiver, the PHY preamble and header are processed to aid in demodulation and delivery of the PSDU.

17.3.2 PPDU format

17.3.2.1 General

Figure 17-1 shows the format for the PPDU including the OFDM PHY preamble, OFDM PHY header, PSDU, tail bits, and pad bits. The PHY header contains the following fields: LENGTH, RATE, a reserved bit, an even parity bit, and the SERVICE field. In terms of modulation, the LENGTH, RATE, reserved bit, and parity bit (with 6 zero tail bits appended) constitute a separate single OFDM symbol, denoted SIGNAL, which is transmitted with the most robust combination of BPSK modulation and a coding rate of $R = 1/2$. The SERVICE field of the PHY header and the PSDU (with 6 zero tail bits and pad bits appended), denoted as DATA, are transmitted at the data rate described in the RATE field and may constitute multiple OFDM symbols. The tail bits in the SIGNAL symbol enable decoding of the RATE and LENGTH fields immediately after the reception of the tail bits. The RATE and LENGTH fields are required for decoding the DATA part of the packet. In addition, the CCA mechanism is augmented by predicting the duration of the packet from the contents of the RATE and LENGTH fields, even if the data rate is not supported by the STA. Each of these fields is described in detail in 17.3.3, 17.3.4, and 17.3.5.

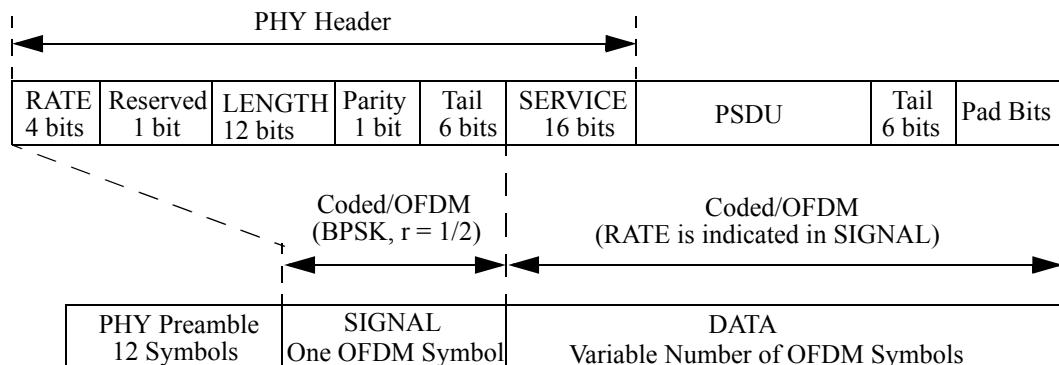

Figure 17-1—PPDU format

17.3.2.2 Overview of the PPDU encoding process

The encoding process is composed of many detailed steps, which are described fully in later subclauses, as noted below. The following overview intends to facilitate understanding the details of the convergence procedure:

- Produce the PHY Preamble field, composed of 10 repetitions of a “short training sequence” (used for AGC convergence, diversity selection, timing acquisition, and coarse frequency acquisition in the receiver) and two repetitions of a “long training sequence” (used for channel estimation and fine frequency acquisition in the receiver), preceded by a guard interval (GI). Refer to 17.3.3 for details.
- Produce the PHY header field from the RATE, LENGTH, and SERVICE fields of the TXVECTOR by filling the appropriate bit fields. The RATE and LENGTH fields of the PHY header are encoded by a convolutional code at a rate of $R = 1/2$, and are subsequently mapped onto a single BPSK

encoded OFDM symbol, denoted as the SIGNAL symbol. In order to facilitate a reliable and timely detection of the RATE and LENGTH fields, 6 zero tail bits are inserted into the PHY header. The encoding of the SIGNAL field into an OFDM symbol follows the same steps for convolutional encoding, interleaving, BPSK modulation, pilot insertion, Fourier transform, and prepending a GI as described subsequently for data transmission with BPSK-OFDM modulated at coding rate 1/2. The contents of the SIGNAL field are not scrambled. Refer to 17.3.4 for details.

- c) Calculate from RATE field of the TXVECTOR the number of data bits per OFDM symbol (N_{DBPS}), the coding rate (R), the number of bits in each OFDM subcarrier (N_{BPSC}), and the number of coded bits per OFDM symbol (N_{CBPS}). Refer to 17.3.2.3 for details.
- d) Append the PSDU to the SERVICE field of the TXVECTOR. Extend the resulting bit string with zero bits (at least 6 bits) so that the resulting length is a multiple of N_{DBPS} . The resulting bit string constitutes the DATA part of the packet. Refer to 17.3.5.4 for details.
- e) If the TXVECTOR parameter CH_BANDWIDTH_IN_NON_HT is not present, initiate the scrambler with a pseudorandom nonzero seed and generate a scrambling sequence. If the TXVECTOR parameter CH_BANDWIDTH_IN_NON_HT is present, construct the first 7 bits of the scrambling sequence from CH_BANDWIDTH_IN_NON_HT, DYN_BANDWIDTH_IN_NON_HT (if present), and a pseudorandom integer constrained such that the first 7 bits of the scrambling sequence are not all 0s; then set the scrambler state to these 7 bits and generate the remainder of the scrambling sequence. XOR the scrambling sequence with the extended string of data bits. Refer to 17.3.5.5 for details.
- f) Replace the six scrambled zero bits following the data with six nonscrambled zero bits. (Those bits return the convolutional encoder to the zero state and are denoted as tail bits.) Refer to 17.3.5.3 for details.
- g) Encode the extended, scrambled data string with a convolutional encoder ($R = 1/2$). Omit (puncture) some of the encoder output string (chosen according to “puncturing pattern”) to reach the “coding rate” corresponding to the TXVECTOR parameter RATE. Refer to 17.3.5.6 for details.
- h) Divide the encoded bit string into groups of N_{CBPS} bits. Within each group, perform an “interleaving” (reordering) of the bits according to a rule corresponding to the TXVECTOR parameter RATE. Refer to 17.3.5.7 for details.
- i) Divide the resulting coded and interleaved data string into groups of N_{BPSC} bits. For each of the bit groups, convert the bit group into a complex number according to the modulation encoding tables. Refer to 17.3.5.8 for details.
- j) Divide the complex number string into groups of 48 complex numbers. Each such group is associated with one OFDM symbol. In each group, the complex numbers are numbered 0 to 47 and mapped hereafter into OFDM subcarriers numbered -26 to -22, -20 to -8, -6 to -1, 1 to 6, 8 to 20, and 22 to 26. The subcarriers -21, -7, 7, and 21 are skipped and, subsequently, used for inserting pilot subcarriers. The 0 subcarrier, associated with center frequency, is omitted and filled with the value 0. Refer to 17.3.5.10 for details.
- k) Four subcarriers are inserted as pilots into positions -21, -7, 7, and 21. The total number of the subcarriers is 52 (48 + 4). Refer to 17.3.5.9 for details.
- l) For each group of subcarriers -26 to 26, convert the subcarriers to time domain using inverse Fourier transform. Prepend to the Fourier-transformed waveform a circular extension of itself thus forming a GI, and truncate the resulting periodic waveform to a single OFDM symbol length by applying time domain windowing. Refer to 17.3.5.10 for details.
- m) Append the OFDM symbols one after another, starting after the SIGNAL symbol describing the RATE and LENGTH fields. Refer to 17.3.5.10 for details.
- n) Upconvert the resulting “complex baseband” waveform to an RF according to the center frequency of the operating channel and transmit. Refer to 17.3.2.5 and 17.3.8.2 for details.

An illustration of the transmitted frame and its parts appears in Figure 17-4 (in 17.3.3).

17.3.2.3 Modulation-dependent parameters

The modulation parameters dependent on the data rate used shall be set according to Table 17-4.

Table 17-4—Modulation-dependent parameters

| Modulation | Coding rate (R) | Coded bits per subcarrier (N_{BPSC}) | Coded bits per OFDM symbol (N_{CBPS}) | Data bits per OFDM symbol (N_{DBPS}) | Data rate (Mb/s) (20 MHz channel spacing) | Data rate (Mb/s) (10 MHz channel spacing) | Data rate (Mb/s) (5 MHz channel spacing) |
|------------|---------------------|--|---|--|---|---|--|
| BPSK | 1/2 | 1 | 48 | 24 | 6 | 3 | 1.5 |
| BPSK | 3/4 | 1 | 48 | 36 | 9 | 4.5 | 2.25 |
| QPSK | 1/2 | 2 | 96 | 48 | 12 | 6 | 3 |
| QPSK | 3/4 | 2 | 96 | 72 | 18 | 9 | 4.5 |
| 16-QAM | 1/2 | 4 | 192 | 96 | 24 | 12 | 6 |
| 16-QAM | 3/4 | 4 | 192 | 144 | 36 | 18 | 9 |
| 64-QAM | 2/3 | 6 | 288 | 192 | 48 | 24 | 12 |
| 64-QAM | 3/4 | 6 | 288 | 216 | 54 | 27 | 13.5 |

17.3.2.4 Timing-related parameters

Table 17-5 is the list of timing parameters associated with the OFDM PHY.

Table 17-5—Timing-related parameters

| Parameter | Value (20 MHz channel spacing) | Value (10 MHz channel spacing) | Value (5 MHz channel spacing) |
|---|---|---|---|
| N_{SD} : Number of data subcarriers | 48 | 48 | 48 |
| N_{SP} : Number of pilot subcarriers | 4 | 4 | 4 |
| N_{ST} : Number of subcarriers, total | $52(N_{SD} + N_{SP})$ | $52(N_{SD} + N_{SP})$ | $52(N_{SD} + N_{SP})$ |
| Δ_F : Subcarrier frequency spacing | 0.3125 MHz (=20 MHz/64) | 0.156 25 MHz (= 10 MHz/64) | 0.078 125 MHz (= 5 MHz/64) |
| T_{FFT} : Inverse Fast Fourier Transform (IFFT) / Fast Fourier Transform (FFT) period | $3.2 \mu\text{s} (1/\Delta_F)$ | $6.4 \mu\text{s} (1/\Delta_F)$ | $12.8 \mu\text{s} (1/\Delta_F)$ |
| $T_{PREAMBLE}$: PHY preamble duration | $16 \mu\text{s} (T_{SHORT} + T_{LONG})$ | $32 \mu\text{s} (T_{SHORT} + T_{LONG})$ | $64 \mu\text{s} (T_{SHORT} + T_{LONG})$ |

Table 17-5—Timing-related parameters (continued)

| Parameter | Value (20 MHz channel spacing) | Value (10 MHz channel spacing) | Value (5 MHz channel spacing) |
|--|--|---|---|
| T_{SIGNAL} : Duration of the SIGNAL BPSK-OFDM symbol | 4.0 μs ($T_{GI} + T_{FFT}$) | 8.0 μs ($T_{GI} + T_{FFT}$) | 16.0 μs ($T_{GI} + T_{FFT}$) |
| T_{GI} : GI duration | 0.8 μs ($T_{FFT}/4$) | 1.6 μs ($T_{FFT}/4$) | 3.2 μs ($T_{FFT}/4$) |
| T_{GI2} : Training symbol GI duration | 1.6 μs ($T_{FFT}/2$) | 3.2 μs ($T_{FFT}/2$) | 6.4 μs ($T_{FFT}/2$) |
| T_{SYM} : Symbol interval | 4 μs ($T_{GI} + T_{FFT}$) | 8 μs ($T_{GI} + T_{FFT}$) | 16 μs ($T_{GI} + T_{FFT}$) |
| T_{SHORT} : Short training sequence duration | 8 μs ($10 \times T_{FFT}/4$) | 16 μs ($10 \times T_{FFT}/4$) | 32 μs ($10 \times T_{FFT}/4$) |
| T_{LONG} : Long training sequence duration | 8 μs ($T_{GI2} + 2 \times T_{FFT}$) | 16 μs ($T_{GI2} + 2 \times T_{FFT}$) | 32 μs ($T_{GI2} + 2 \times T_{FFT}$) |

17.3.2.5 Mathematical conventions in the signal descriptions

The transmitted signals are described in a complex baseband signal notation. The actual transmitted signal is related to the complex baseband signal by the following relation:

$$r_{(RF)}(t) = \operatorname{Re}\{r(t)\exp(j2\pi f_c t)\} \quad (17-1)$$

where

f_c denotes the carrier center frequency

The transmitted baseband signal is composed of contributions from several OFDM symbols.

$$r_{PACKET}(t) = r_{PREAMBLE}(t) + r_{SIGNAL}(t - t_{SIGNAL}) + r_{DATA}(t - t_{DATA}) \quad (17-2)$$

The subframes of which Equation (17-2) are composed are described in 17.3.3, 17.3.4, and 17.3.5.10. The time offsets $t_{SUBFRAME}$ determine the starting time of the corresponding subframe; t_{SIGNAL} is equal to 16 μs for 20 MHz channel spacing, 32 μs for 10 MHz channel spacing, and 64 μs for 5 MHz channel spacing, and t_{DATA} is equal to 20 μs for 20 MHz channel spacing, 40 μs for 10 MHz channel spacing, and 80 μs for 5 MHz channel spacing.

All of the subframes of the signal are constructed as an inverse Fourier transform of a set of coefficients, C_k , with C_k defined later as data, pilots, or training symbols in 17.3.3 to 17.3.5.

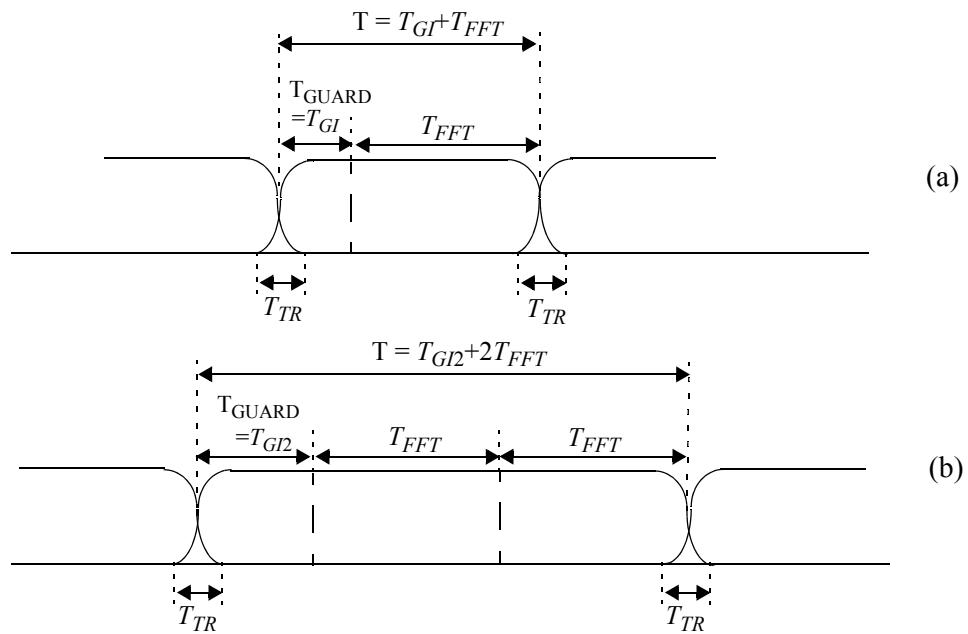

$$r_{SUBFRAME}(t) = w_{TSUBFRAME}(t) \sum_{k=-N_{ST}/2}^{N_{ST}/2} C_k \exp(j2\pi k \Delta_f)(t - T_{GUARD}) \quad (17-3)$$

The parameters Δ_f and N_{ST} are described in Table 17-5. The resulting waveform is periodic with a period of $T_{FFT} = 1/\Delta_f$. Shifting the time by T_{GUARD} creates the “circular prefix” used in OFDM to avoid ISI from the previous frame. Three kinds of T_{GUARD} are defined: for the short training sequence (= 0 μs), for the long training sequence (= T_{GI2}), and for data OFDM symbols (= T_{GI}). (Refer to Table 17-5.) The boundaries of

the subframe are set by a multiplication by a time-windowing function, $w_{T\text{SUBFRAME}}(t)$, which is defined as a rectangular pulse, $w_T(t)$, of duration T , accepting the value T_{SUBFRAME} . The time-windowing function, $w_T(t)$, depending on the value of the duration parameter, T , may extend over more than one period, T_{FFT} . In particular, window functions that extend over multiple periods of the FFT are utilized in the definition of the preamble. Figure 17-2 illustrates the possibility of extending the windowing function over more than one period, T_{FFT} , and additionally shows smoothed transitions by application of a windowing function, as exemplified in Equation (17-4). In particular, window functions that extend over multiple periods of the FFT are utilized in the definition of the preamble.

$$w_T(t) = \begin{cases} \sin^2\left(\frac{\pi}{2}(0.5 + t/T_{TR})\right) & (-T_{TR}/2 < t < T_{TR}/2) \\ 1 & (T_{TR}/2 \leq t < T - T_{TR}/2) \\ \sin^2\left(\frac{\pi}{2}(0.5 - (t - T)/T_{TR})\right) & (T - T_{TR}/2 \leq t < T + T_{TR}/2) \end{cases} \quad (17-4)$$

In the case of vanishing T_{TR} , the windowing function degenerates into a rectangular pulse of duration T . This standard describes transmitted waveforms using a rectangular pulse shape. In a typical implementation, a higher T_{TR} is used in order to smooth the transitions between consecutive subsections. This creates a small overlap between them, of duration T_{TR} , as shown in Figure 17-2. The transition time, T_{TR} , is about 100 ns. Smoothing the transition is required in order to reduce the spectral sidelobes of the transmitted waveform. However, the binding requirements are the spectral mask and modulation accuracy requirements, as detailed in 17.3.9.3 and 17.3.9.7. Time domain windowing, as described here, is just one way to achieve those objectives. The implementer may use other methods to achieve the same goal, such as frequency domain filtering. Therefore, the transition shape and duration of the transition are informative parameters.

**Figure 17-2—Illustration of OFDM frame with cyclic extension and windowing for
 (a) single reception or (b) two receptions of the FFT period**

17.3.2.6 Discrete time implementation considerations

The following descriptions of the discrete time implementation are informational.

In a typical implementation, the windowing function is represented in discrete time. As an example, when a windowing function with parameters $T = 4.0 \mu\text{s}$ and a $T_{TR} = 100 \text{ ns}$ is applied, and the signal is sampled at 20 Msample/s, it becomes

$$w_T[n] = w_T(nT_S) = \begin{cases} 1 & 1 \leq n \leq 79 \\ 0.5 & 0, 80 \\ 0 & otherwise \end{cases} \quad (17-5)$$

The common way to implement the inverse Fourier transform, as shown in Equation (17-3), is by an IFFT algorithm. If, for example, a 64-point IFFT is used, the coefficients 1 to 26 are mapped to the same numbered IFFT inputs, while the coefficients -26 to -1 are copied into IFFT inputs 38 to 63. The rest of the inputs, 27 to 37 and the 0 (dc) input, are set to 0. This mapping is illustrated in Figure 17-3. After performing an IFFT, the output is cyclically extended and the resulting waveform is windowed to the required OFDM symbol length.

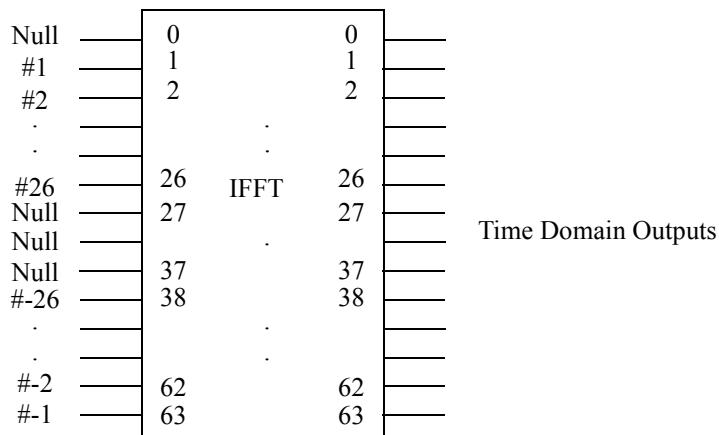

Figure 17-3—Inputs and outputs of inverse Fourier transform

17.3.3 PHY preamble (SYNC)

The PHY Preamble field is used for synchronization. It consists of 10 short symbols and two long symbols that are shown in Figure 17-4 and described in this subclause. The timings described in this subclause and shown in Figure 17-4 are for 20 MHz channel spacing. They are doubled for half-clocked (i.e., 10 MHz) channel spacing and are quadrupled for quarter-clocked (i.e., 5 MHz) channel spacing.

Figure 17-4 shows the OFDM training structure (PHY preamble), where t_1 to t_{10} denote short training symbols and T_1 and T_2 denote long training symbols. The PHY preamble is followed by the SIGNAL field and DATA. The total training length is $16 \mu\text{s}$. The dashed boundaries in the figure denote repetitions due to the periodicity of the inverse Fourier transform.

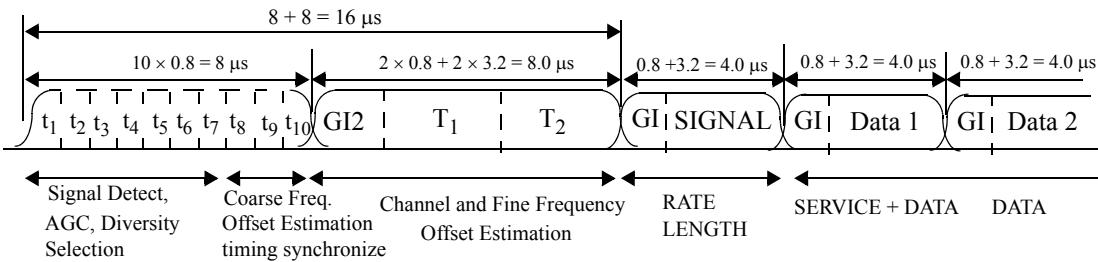

Figure 17-4—OFDM training structure

A short OFDM training symbol consists of 12 subcarriers, which are modulated by the elements of the sequence S , given by

$$S_{-26, 26} = \sqrt{(13/6)} \times \{0, 0, 1+j, 0, 0, 0, -1-j, 0, 0, 0, 1+j, 0, 0, 0, -1-j, 0, 0, 0, -1-j, 0, 0, 0, 1+j, 0, 0, 0, 0, 0, \\ 0, 0, 0, -1-j, 0, 0, 0, -1-j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0, 0, 1+j, 0, 0\} \quad (17-6)$$

The multiplication by a factor of $\sqrt{13/6}$ is in order to normalize the average power of the resulting OFDM symbol, which utilizes 12 out of 52 subcarriers.

The signal shall be generated according to the following equation:

$$r_{SHORT}(t) = w_{TSHORT}(t) \sum_{k=-N_{ST}/2}^{N_{ST}/2} S_k \exp(j2\pi k \Delta_F t) \quad (17-7)$$

The fact that only spectral lines of S_{26:26} with indices that are a multiple of 4 have nonzero amplitude results in a periodicity of $T_{FFT}/4 = 0.8 \mu\text{s}$. The interval T_{SHORT} is equal to ten 0.8 μs periods (i.e., 8 μs).

Generation of the short training sequence is illustrated in Table I-2.

A long OFDM training symbol consists of 53 subcarriers (including the value 0 at dc), which are modulated by the elements of the sequence L , given by

$$L_{-26,26} = \{1, 1, -1, -1, 1, 1, -1, 1, -1, 1, 1, 1, 1, 1, 1, -1, -1, 1, 1, -1, 1, -1, 1, -1, 1, 1, 1, 1, 0, \\ 1, -1, -1, 1, 1, -1, 1, -1, -1, -1, -1, 1, 1, -1, -1, 1, -1, 1, -1, 1, -1, 1, 1, 1, 1, 1\} \quad (17-8)$$

A long OFDM training symbol shall be generated according to the following equation:

$$r_{LONG}(t) = w_{TLONG}(t) \sum_{k=-N_{ST}/2}^{N_{ST}/2} L_k \exp(j2\pi k \Delta_F(t - T_{G12})) \quad (17-9)$$

where

$$T_{G\,12} = 1.6 \text{ } \mu\text{s}$$

Two periods of the long sequence are transmitted for improved channel estimation accuracy, yielding $T_{LONG} = 1.6 + 2 \times 3.2 = 8 \mu\text{s}$.

An illustration of the long training sequence generation is given in Table I-5.

The sections of short repetitions and long repetitions shall be concatenated to form the preamble

$$r_{PREAMBLE}(t) = r_{SHORT}(t) + r_{LONG}(t - T_{SHORT}) \quad (17-10)$$

17.3.4 SIGNAL field

17.3.4.1 General

The OFDM training symbols shall be followed by the SIGNAL field, which contains the RATE and the LENGTH fields of the TXVECTOR. The RATE field conveys information about the type of modulation and the coding rate as used in the rest of the packet. The encoding of the SIGNAL single OFDM symbol shall be performed with BPSK modulation of the subcarriers and using convolutional coding at $R = 1/2$. The encoding procedure, which includes convolutional encoding, interleaving, modulation mapping processes, pilot insertion, and OFDM modulation, follows the steps described in 17.3.5.6, 17.3.5.7, and 17.3.5.9, as used for transmission of data with BPSK-OFDM modulated at coding rate 1/2. The contents of the SIGNAL field are not scrambled.

The SIGNAL field shall be composed of 24 bits, as illustrated in Figure 17-5. The four bits 0 to 3 shall encode the RATE. Bit 4 shall be reserved for future use. Bits 5–16 shall encode the LENGTH field of the TXVECTOR, with the LSB being transmitted first.

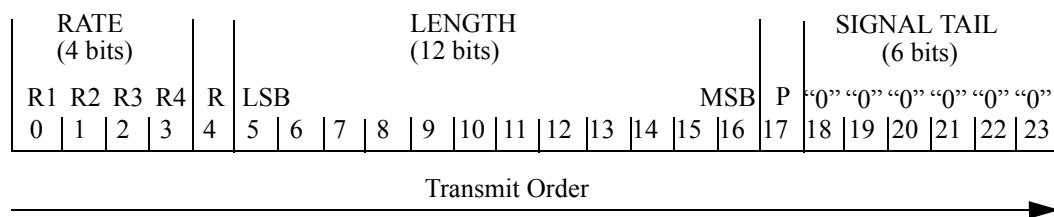

Figure 17-5—SIGNAL field bit assignment

The process of generating the SIGNAL OFDM symbol is illustrated in I.1.4.

17.3.4.2 RATE field

The bits R1–R4 shall be set, dependent on RATE, according to the values in Table 17-6.

Table 17-6—Contents of the SIGNAL field

| R1–R4 | Rate (Mb/s) (20 MHz channel spacing) | Rate (Mb/s) (10 MHz channel spacing) | Rate (Mb/s) (5 MHz channel spacing) |
|-------|---|---|--|
| 1101 | 6 | 3 | 1.5 |
| 1111 | 9 | 4.5 | 2.25 |
| 0101 | 12 | 6 | 3 |
| 0111 | 18 | 9 | 4.5 |
| 1001 | 24 | 12 | 6 |

Table 17-6—Contents of the SIGNAL field (continued)

| R1-R4 | Rate (Mb/s) (20 MHz channel spacing) | Rate (Mb/s) (10 MHz channel spacing) | Rate (Mb/s) (5 MHz channel spacing) |
|-------|--|--|---|
| 1011 | 36 | 18 | 9 |
| 0001 | 48 | 24 | 12 |
| 0011 | 54 | 27 | 13.5 |

17.3.4.3 PHY LENGTH field

The PHY LENGTH field shall be an unsigned 12-bit integer that indicates the number of octets in the PSDU that the MAC is currently requesting the PHY to transmit. This value is used by the PHY to determine the number of octet transfers that will occur between the MAC and the PHY after receiving a request to start transmission. The transmitted value shall be determined from the LENGTH parameter in the TXVECTOR issued with the PHY-TXSTART.request primitive described in 8.3.5.5. The LSB shall be transmitted first in time. This field shall be encoded by the convolutional encoder described in 17.3.5.6.

17.3.4.4 Parity (P), Reserved (R), and SIGNAL TAIL fields

Bit 4 is reserved. It shall be set to 0 on transmit and ignored on receive. Bit 17 shall be a positive parity (even parity) bit for bits 0–16. The bits 18–23 constitute the SIGNAL TAIL field, and all 6 bits shall be set to 0.

17.3.5 DATA field

17.3.5.1 General

The DATA field contains the SERVICE field, the PSDU, the TAIL bits, and the PAD bits, if needed, as described in 17.3.5.3 and 17.3.5.4. All bits in the DATA field are scrambled, as described in 17.3.5.5.

17.3.5.2 SERVICE field

The SERVICE field has 16 bits, which shall be denoted as bits 0–15. The bit 0 shall be transmitted first in time. The bits from 0–6 of the SERVICE field, which are transmitted first, are set to 0s and are used to synchronize the descrambler in the receiver. The remaining 9 bits (7–15) of the SERVICE field shall be reserved for future use. All reserved bits shall be set to 0 on transmission and ignored on reception. Refer to Figure 17-6.

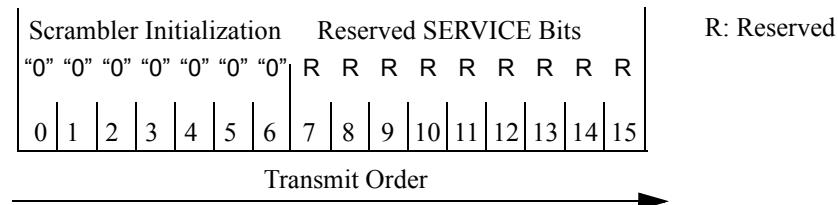

Figure 17-6—SERVICE field bit assignment

17.3.5.3 PPDU TAIL field

The PPDU TAIL field shall be six bits of 0, which are required to return the convolutional encoder to the zero state. This procedure improves the error probability of the convolutional decoder, which relies on future bits when decoding and which may be not be available past the end of the message. The PPDU TAIL field shall be produced by replacing six scrambled zero bits following the message end with six nonscrambled zero bits.

17.3.5.4 Pad bits (PAD)

The number of bits in the DATA field shall be a multiple of N_{CBPS} , the number of coded bits in an OFDM symbol (48, 96, 192, or 288 bits). To achieve that, the length of the message is extended so that it becomes a multiple of N_{DBPS} , the number of data bits per OFDM symbol. At least 6 bits are appended to the message, in order to accommodate the TAIL bits, as described in 17.3.5.3. The number of OFDM symbols, N_{SYM} ; the number of bits in the DATA field, N_{DATA} ; and the number of pad bits, N_{PAD} , are computed from the length of the PSDU (LENGTH) as follows:

$$N_{SYM} = \left\lceil \frac{16 + 8 \times \text{LENGTH} + 6}{N_{DBPS}} \right\rceil \quad (17-11)$$

$$N_{DATA} = N_{SYM} \times N_{DBPS} \quad (17-12)$$

$$N_{PAD} = N_{DATA} - (16 + 8 \times \text{LENGTH} + 6) \quad (17-13)$$

The appended bits (“pad bits”) are set to 0 and are subsequently scrambled with the rest of the bits in the DATA field.

An example of a DATA field that contains the SERVICE field, PSDU, tail, and pad parts is given in I.1.5.1.

17.3.5.5 PHY DATA scrambler and descrambler

The DATA field, composed of SERVICE, PSDU, tail, and pad parts, shall be scrambled with a length-127 PPDU-synchronous scrambler. The octets of the PSDU are placed in the transmit serial bit stream, bit 0 first and bit 7 last. The PPDU synchronous scrambler uses the generator polynomial $S(x)$ as follows and is illustrated in Figure 17-7:

$$S(x) = x^7 + x^4 + 1 \quad (17-14)$$

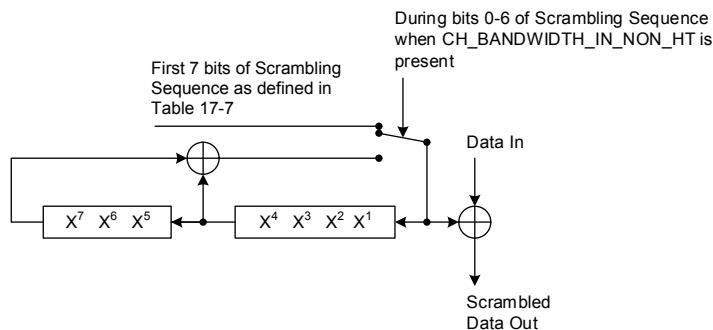

Figure 17-7—Data scrambler

The 127-bit sequence generated repeatedly by the scrambler shall be (leftmost used first), 00001110 11110010 11001001 00000010 00100110 00101110 10110110 00001100 11010100 11100111 10110100 00101010 11111010 01010001 10111000 1111111, when the all 1s initial state is used. The same scrambler is used to scramble transmit data and to descramble receive data. If the TXVECTOR parameter CH_BANDWIDTH_IN_NON_HT is not present, when transmitting, the initial state of the scrambler shall be set to a pseudorandom nonzero state. If the TXVECTOR parameter CH_BANDWIDTH_IN_NON_HT is present,

- The first 7 bits of the scrambling sequence shall be set as shown in Table 17-7 (with field values defined in Table 17-8 and Table 17-10) and shall be also used to initialize the state of the scrambler
- The scrambler with this initialization shall generate the remainder (i.e., after the first 7 bits) of the scrambling sequence as shown in Figure 17-7
- CH_BANDWIDTH_IN_NON_HT is transmitted LSB first. For example, if CBW80 has a value of 2, which is ‘10’ in binary representation, then B5=0 and B6=1

Table 17-7—Contents of the first 7 bits of the scrambling sequence

| Parameter | Condition | First 7 bits of scrambling sequence | | | | | |
|-----------|--|---|----|-------------------------|----|--|------------------------|
| | | B0 | B3 | B4 | B5 | B6 | Transmit order |
| TXVECTOR | CH_BANDWIDTH_IN_NON_HT is present and DYN_BANDWIDTH_IN_NOT_HT is not present in TXVECTOR | 5-bit pseudorandom nonzero integer if CH_BANDWIDTH_IN_NON_HT equals CBW20 and a 5-bit pseudorandom integer otherwise | | | | | CH_BANDWIDTH_IN_NON_HT |
| TXVECTOR | CH_BANDWIDTH_IN_NON_HT is present and DYN_BANDWIDTH_IN_NOT_HT is present in TXVECTOR | 4-bit pseudorandom nonzero integer if CH_BANDWIDTH_IN_NON_HT equals CBW20 and DYN_BANDWIDTH_IN_NON_HT equals Static, and a 4-bit pseudorandom integer otherwise | | DYN_BANDWIDTH_IN_NON_HT | | | |
| RXVECTOR | CH_BANDWIDTH_IN_NON_HT and DYN_BANDWIDTH_IN_NOT_HT are present in RXVECTOR | — | | DYN_BANDWIDTH_IN_NON_HT | | CbwInNonHtTemp is set to this subfield of first 7 bits of scrambling sequence; then CbwInNonHtTemp is mapped according to Table 17-9 to CH_BANDWIDTH_IN_NON_HT | |

Table 17-8—TXVECTOR parameter CH_BANDWIDTH_IN_NON_HT values

| Enumerated value | Value |
|--------------------|-------|
| CBW20 | 0 |
| CBW40 | 1 |
| CBW80 | 2 |
| CBW160 or CBW80+80 | 3 |

During reception by a VHT STA, the CbwInNonHtTemp variable shall be set to selected bits in the scrambling sequence as shown in Table 17-7 and then mapped as shown in Table 17-9 to the RXVECTOR parameter CH_BANDWIDTH_IN_NON_HT. During reception by a VHT STA, the RXVECTOR parameter DYN_BANDWIDTH_IN_NON_HT shall be set to selected bits in the scrambling sequence as shown in Table 17-7. The fields shall be interpreted as being sent LSB-first.

Table 17-9—RXVECTOR parameter CH_BANDWIDTH_IN_NON_HT values

| CbwInNonHtTemp (see Table 17-7) | dot11CurrentChannelCenter FrequencyIndex1 | RXVECTOR parameter CH_BANDWIDTH_IN_NON_HT |
|------------------------------------|--|--|
| 0 | 0 | CBW20 |
| 1 | 0 | CBW40 |
| 2 | 0 | CBW80 |
| 3 | 0 | CBW160 |
| 3 | 1 to 200 | CBW80+80 |

Table 17-10—DYN_BANDWIDTH_IN_NON_HT values

| Enumerated value | Value |
|------------------|-------|
| Static | 0 |
| Dynamic | 1 |

NOTE 1—The receiving PHY cannot determine whether the CH_BANDWIDTH_IN_NON_HT and DYN_BANDWIDTH_IN_NON_HT parameters were present in the TXVECTOR of the transmitting PHY; therefore, the receiving PHY in a VHT STA always includes values for the CH_BANDWIDTH_IN_NON_HT and DYN_BANDWIDTH_IN_NON_HT parameters in the RXVECTOR if the detected PPDU is a non-HT PPDU. It is the responsibility of the MAC to determine the validity of the RXVECTOR parameters CH_BANDWIDTH_IN_NON_HT and DYN_BANDWIDTH_IN_NON_HT.

NOTE 2—The receiving PHY cannot determine whether the TXVECTOR parameter CH_BANDWIDTH_IN_NON_HT was present, but it does not matter since descrambling the DATA field is the same either way.

The seven LSBs of the SERVICE field shall be set to all 0s prior to scrambling to enable estimation of the initial state of the scrambler in the receiver.

An example of the scrambler output is illustrated in I.1.5.2 with CH_BANDWIDTH_IN_NON_HT not present.

17.3.5.6 Convolutional encoder

The DATA field, composed of SERVICE, PSDU, tail, and pad parts, shall be coded with a convolutional encoder of coding rate $R = 1/2, 2/3$, or $3/4$, corresponding to the TXVECTOR parameter RATE. The convolutional encoder shall use the industry-standard generator polynomials, $g_0 = 133_g$ and $g_1 = 171_g$, of rate $R = 1/2$, as shown in Figure 17-8. The bit denoted as “A” shall be output from the encoder before the bit denoted as “B.” Higher rates are derived from it by employing “puncturing.” Puncturing is a procedure for omitting some of the encoded bits in the transmitter (thus reducing the number of transmitted bits and increasing the coding rate) and inserting a dummy “zero” metric into the convolutional decoder on the receive side in place of the omitted bits. The puncturing patterns are illustrated in Figure 17-9. Decoding by the Viterbi algorithm is recommended.

An example of encoding operation is shown in I.1.6.1.

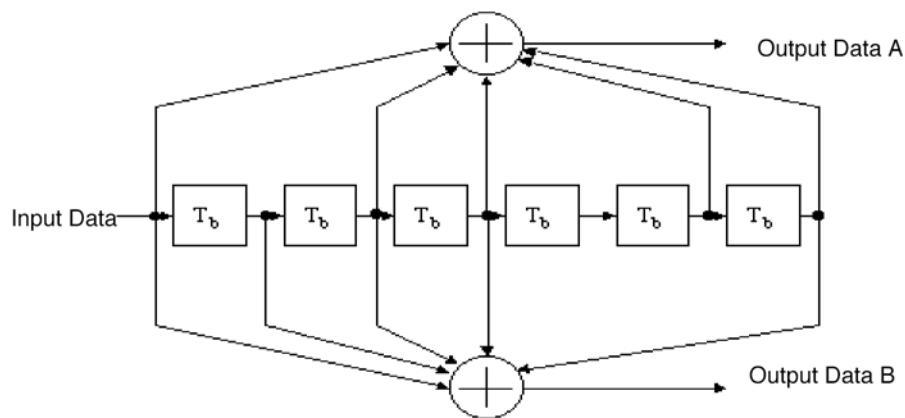

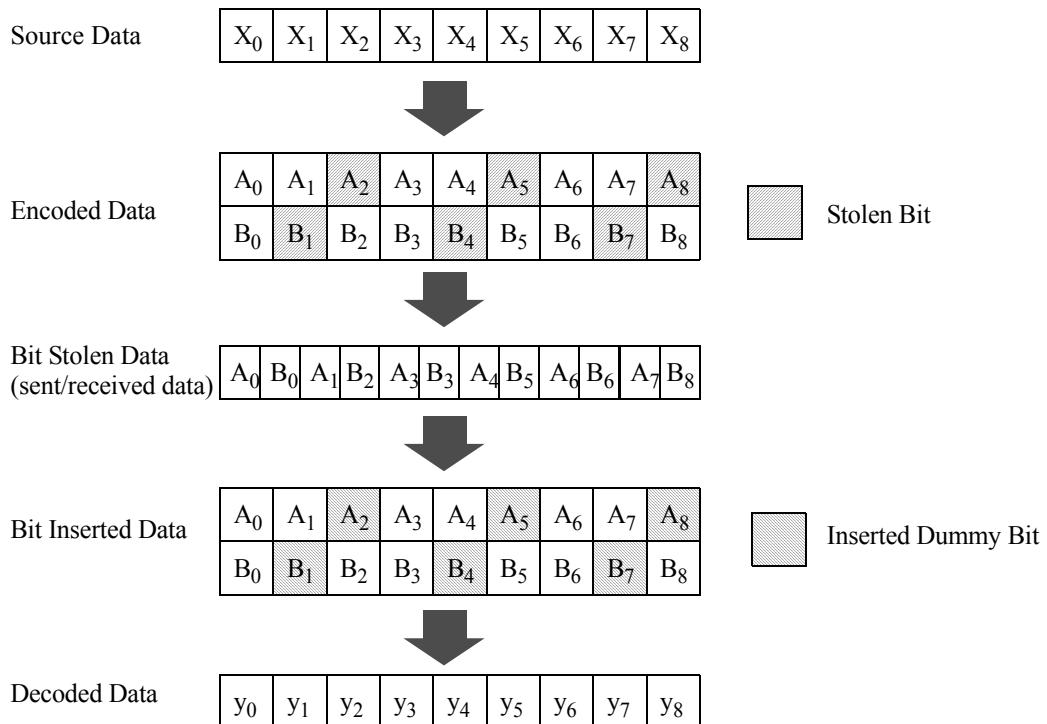

Figure 17-8—Convolutional encoder ($k = 7$)

Punctured Coding ($r = 3/4$)

Punctured Coding ($r = 2/3$)

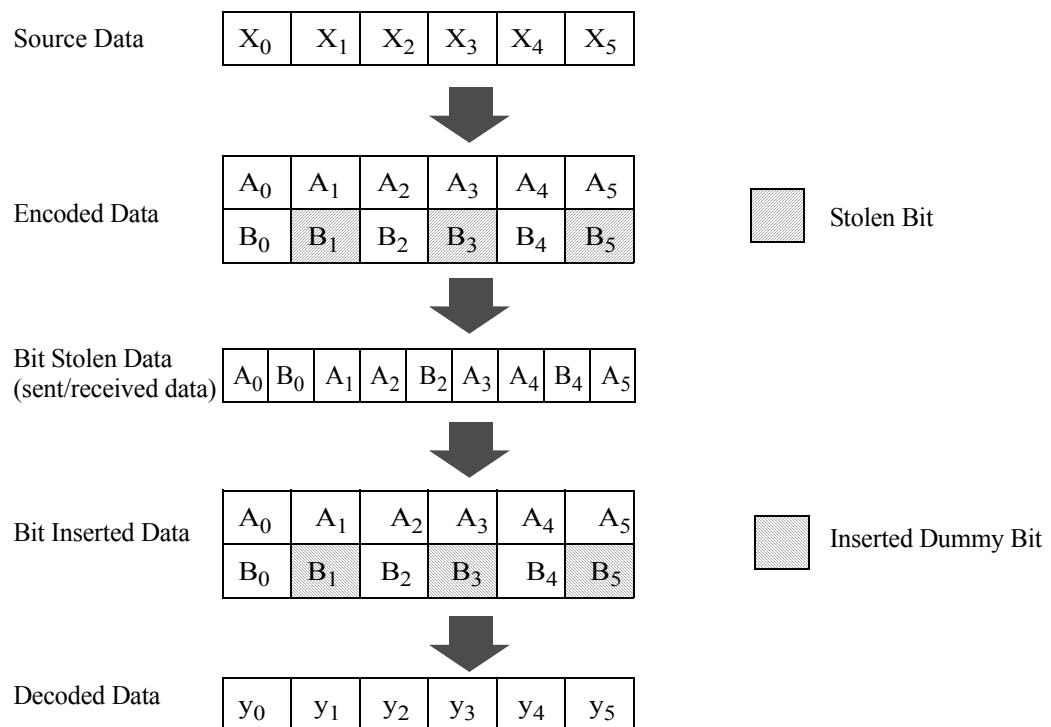

Figure 17-9—Example of the bit-stealing and bit-insertion procedure ($r = 3/4, 2/3$)

17.3.5.7 Data interleaving

All encoded data bits shall be interleaved by a block interleaver with a block size corresponding to the number of bits in a single OFDM symbol, N_{CBPS} . The interleaver is defined by a two-step permutation. The first permutation causes adjacent coded bits to be mapped onto nonadjacent subcarriers. The second causes adjacent coded bits to be mapped alternately onto less and more significant bits of the constellation and, thereby, long runs of low reliability (LSB) bits are avoided.

The index of the coded bit before the first permutation shall be denoted by k ; i shall be the index after the first and before the second permutation; and j shall be the index after the second permutation, just prior to modulation mapping.

The first permutation is defined by the rule

$$i = (N_{CBPS}/16) \times (k \bmod 16) + \lfloor k/16 \rfloor \quad k = 0, 1, \dots, N_{CBPS}-1 \quad (17-15)$$

The second permutation is defined by the rule

$$j = s \times \left\lfloor \frac{i}{s} \right\rfloor + \left(i + N_{CBPS} - \left\lfloor \frac{16 \times i}{N_{CBPS}} \right\rfloor \right) \bmod s \quad i = 0, 1, \dots, N_{CBPS}-1 \quad (17-16)$$

The value of s is determined by the number of coded bits per subcarrier, N_{BPSC} , according to

$$s = \max(N_{BPSC}/2, 1) \quad (17-17)$$

The deinterleaver, which performs the inverse relation, is also defined by two permutations.

Here the index of the original received bit before the first permutation shall be denoted by j ; i shall be the index after the first and before the second permutation; and k shall be the index after the second permutation, just prior to delivering the coded bits to the convolutional (Viterbi) decoder.

The first permutation is defined by the rule

$$i = s \times \lfloor j/s \rfloor + \left(j + \left\lfloor \frac{16 \times j}{N_{CBPS}} \right\rfloor \right) \bmod s \quad j = 0, 1, \dots, N_{CBPS}-1 \quad (17-18)$$

where

s is defined in Equation (17-17).

This permutation is the inverse of the permutation described in Equation (17-16).

The second permutation is defined by the rule

$$k = 16 \times i - (N_{CBPS}-1) \times \left\lfloor \frac{16 \times i}{N_{CBPS}} \right\rfloor, \quad i = 0, 1, \dots, N_{CBPS}-1 \quad (17-19)$$

This permutation is the inverse of the permutation described in Equation (17-15).

An example of interleaving operation is illustrated in I.1.6.2.

17.3.5.8 Subcarrier modulation mapping

The OFDM subcarriers shall be modulated by using BPSK, QPSK, 16-QAM, or 64-QAM, depending on the RATE requested. The encoded and interleaved binary serial input data shall be divided into groups of N_{BPSC} (1, 2, 4, or 6) bits and converted into complex numbers representing BPSK, QPSK, 16-QAM, or 64-QAM constellation points. The conversion shall be performed according to Gray-coded constellation mappings, illustrated in Figure 17-10, with the input bit, B_0 , being the earliest in the stream. The output values, d , are formed by multiplying the resulting $(I+jQ)$ value by a normalization factor K_{MOD} , as described in Equation (17-20).

$$d = (I + jQ) \times K_{MOD} \quad (17-20)$$

The normalization factor, K_{MOD} , depends on the base modulation mode, as prescribed in Table 17-11. Note that the modulation type can be different from the start to the end of the transmission, as the signal changes from SIGNAL to DATA, as shown in Figure 17-1. The purpose of the normalization factor is to achieve the same average power for all mappings. In practical implementations, an approximate value of the normalization factor may be used, as long as the device complies with the modulation accuracy requirements described in 17.3.9.7.

Table 17-11—Modulation-dependent normalization factor K_{MOD}

| Modulation | K_{MOD} |
|------------|---------------|
| BPSK | 1 |
| QPSK | $1/\sqrt{2}$ |
| 16-QAM | $1/\sqrt{10}$ |
| 64-QAM | $1/\sqrt{42}$ |

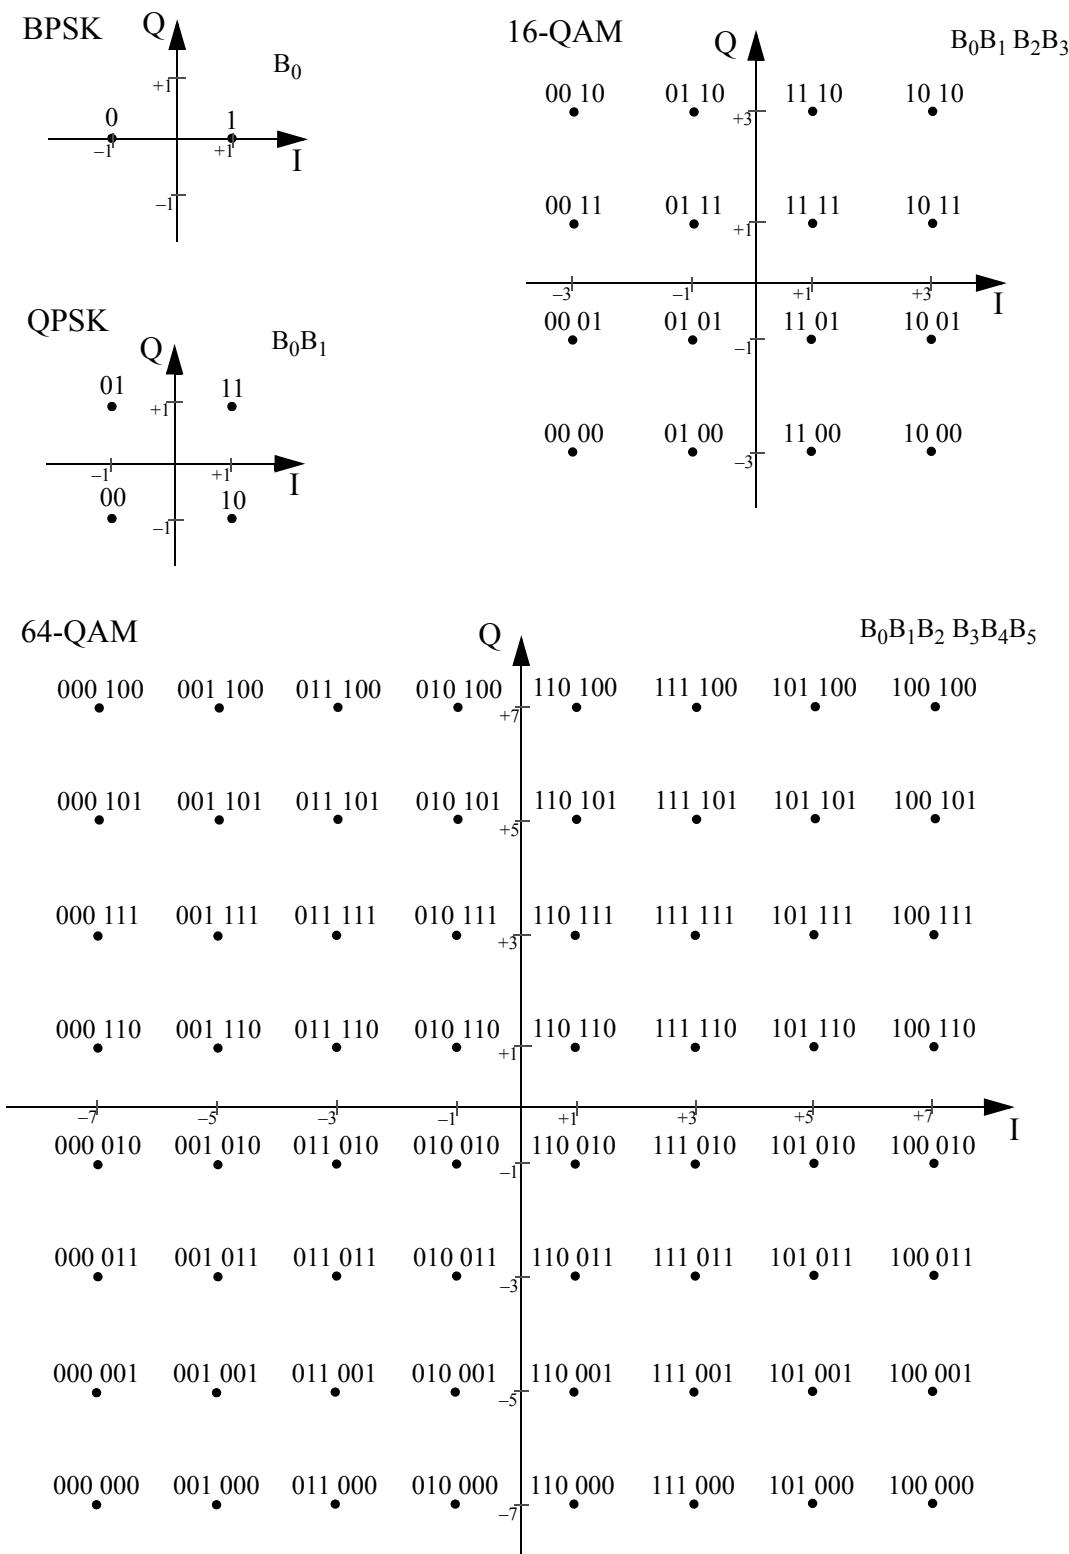

Figure 17-10—BPSK, QPSK, 16-QAM, and 64-QAM constellation bit encoding

For BPSK, B_0 determines the I value, as illustrated in Table 17-12. For QPSK, B_0 determines the I value and B_1 determines the Q value, as illustrated in Table 17-13. For 16-QAM, B_0B_1 determines the I value and B_2B_3 determines the Q value, as illustrated in Table 17-14. For 64-QAM, $B_0B_1B_2$ determines the I value and $B_3B_4B_5$ determines the Q value, as illustrated in Table 17-15.

Table 17-12—BPSK encoding table

| Input bit (B_0) | I-out | Q-out |
|---------------------|-------|-------|
| 0 | -1 | 0 |
| 1 | 1 | 0 |

Table 17-13—QPSK encoding table

| Input bit (B_0) | I-out | Input bit (B_1) | Q-out |
|---------------------|-------|---------------------|-------|
| 0 | -1 | 0 | -1 |
| 1 | 1 | 1 | 1 |

Table 17-14—16-QAM encoding table

| Input bits ($B_0 B_1$) | I-out | Input bits ($B_2 B_3$) | Q-out |
|--------------------------|-------|--------------------------|-------|
| 00 | -3 | 00 | -3 |
| 01 | -1 | 01 | -1 |
| 11 | 1 | 11 | 1 |
| 10 | 3 | 10 | 3 |

Table 17-15—64-QAM encoding table

| Input bits ($B_0 B_1 B_2$) | I-out | Input bits ($B_3 B_4 B_5$) | Q-out |
|------------------------------|-------|------------------------------|-------|
| 000 | -7 | 000 | -7 |
| 001 | -5 | 001 | -5 |
| 011 | -3 | 011 | -3 |
| 010 | -1 | 010 | -1 |
| 110 | 1 | 110 | 1 |
| 111 | 3 | 111 | 3 |
| 101 | 5 | 101 | 5 |
| 100 | 7 | 100 | 7 |

17.3.5.9 Pilot subcarriers

In each OFDM symbol, four of the subcarriers are dedicated to pilot signals in order to make the coherent detection robust against frequency offsets and phase noise. These pilot signals shall be put in subcarriers -21 , -7 , 7 , and 21 . The pilots shall be BPSK modulated by a pseudo-binary sequence to prevent the generation of spectral lines. The contribution of the pilot subcarriers to each OFDM symbol is described in 17.3.5.10.

17.3.5.10 OFDM modulation

The stream of complex numbers is divided into groups of $N_{SD} = 48$ complex numbers. This shall be denoted by writing the complex number $d_{k,n}$, which corresponds to subcarrier k of OFDM symbol n , as follows:

$$d_{k,n} \equiv d_{k+N_{SD} \times n}, \quad k = 0, \dots N_{SD}-1, n = 0, \dots N_{SYM}-1 \quad (17-21)$$

The number of OFDM symbols, N_{SYM} , was introduced in 17.3.5.4.

An OFDM symbol, $r_{DATA,n}(t)$, is defined as

$$r_{DATA,n}(t) = w_{TSYM}(t) \left(\sum_{k=0}^{N_{SD}-1} d_{k,n} \exp((j2\pi M(k)\Delta_F(t - T_{GI})) + p_{n+1} \sum_{k=-N_{ST}/2}^{N_{ST}/2} P_k \exp(j2\pi k\Delta_F(t - T_{GI})) \right) \quad (17-22)$$

where the function, $M(k)$, defines a mapping from the logical subcarrier number 0 to 47 into frequency offset index -26 to 26 , while skipping the pilot subcarrier locations and the 0^{th} (dc) subcarrier.

$$M(k) = \begin{cases} k - 26 & 0 \leq k \leq 4 \\ k - 25 & 5 \leq k \leq 17 \\ k - 24 & 18 \leq k \leq 23 \\ k - 23 & 24 \leq k \leq 29 \\ k - 22 & 30 \leq k \leq 42 \\ k - 21 & 43 \leq k \leq 47 \end{cases} \quad (17-23)$$

The contribution of the pilot subcarriers for the n^{th} OFDM symbol is produced by inverse Fourier transform of sequence P , given by

The polarity of the pilot subcarriers is controlled by the sequence, p_n , which is a cyclic extension of the 127 elements sequence and is given by

$$p_{0..126v} = \{1,1,1,1, -1,-1,-1,1, -1,-1,-1,-1, 1,1,-1,1, -1,-1,1,1, -1,1,1,-1, 1,1,1,1, 1,1,-1,1, 1,1,-1,1, 1,-1,1,1, 1,-1,-1,1, 1,1,-1,1, -1,1,-1,1, 1,-1,-1,1, 1,1,1,1, -1,-1,1,1, -1,-1,1,1, 1,-1,1,1, 1,1,-1,1, -1,1,-1,1, 1,-1,-1,1, 1,1,-1,1, -1,1,1,1, 1,1,-1,1, -1,-1,-1,1, 1,-1,1,-1, 1,1,1,-1, -1,1,-1,-1, 1,1,1,1, -1,-1,-1,1, 1,-1,-1,-1\} \quad (17-25)$$

The sequence p_n is generated by the scrambler defined by Figure 17-7 when the all 1s initial state is used, and by replacing all 1s with -1 and all 0s with 1. Each sequence element is used for one OFDM symbol. The first element, p_0 , multiplies the pilot subcarriers of the SIGNAL symbol, while the elements from p_1 on are used for the DATA symbols.

The subcarrier frequency allocation is shown in Figure 17-11. To avoid difficulties in D/A and A/D converter offsets and carrier feedthrough in the RF system, the subcarrier falling at DC (0^{th} subcarrier) is not used.

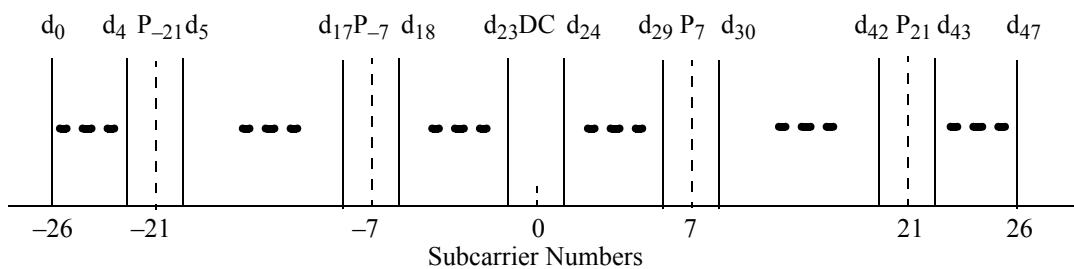

Figure 17-11—Subcarrier frequency allocation

The concatenation of N_{SYM} OFDM symbols is written as

$$r_{\text{DATA}}(t) = \sum_{n=0}^{N_{\text{SYM}}-1} r_{\text{DATA},n}(t-nT_{\text{SYM}}) \quad (17-26)$$

An example of mapping into symbols is shown in I.1.6.3, as well as the scrambling of the pilot signals (see I.1.7). The final output of these operations is also shown in I.1.8.

17.3.6 CCA

The PHY shall provide the capability to perform CCA and report the result to the MAC. The CCA mechanism shall detect a “medium busy” condition with requirements specified in 17.3.10.6 and 17.3.12. The PHY issues the PHY-CCA.indication primitive to provide this medium status report to the MAC.

17.3.7 PHY data modulation and modulation rate change

The PHY preamble shall be transmitted using an OFDM modulated fixed waveform. The SIGNAL field, BPSK-OFDM modulated with coding rate 1/2, shall indicate the modulation and coding rate that shall be used to transmit the MPDU. The transmitter (receiver) shall initiate the modulation (demodulation) constellation and the coding rate according to the RATE indicated in the SIGNAL field. The MPDU transmission rate shall be set by the DATARATE parameter in the TXVECTOR, issued with the PHY-TXSTART.request primitive described in 17.2.2.

17.3.8 PHY operating specifications (general)

17.3.8.1 General

General specifications for the BPSK OFDM, QPSK OFDM, 16-QAM OFDM, and 64-QAM OFDM PHY sublayers are provided in 17.3.8.2 to 17.3.8.7. These specifications apply to both the receive and transmit functions and general operation of the OFDM PHY.

17.3.8.2 Outline description

The general block diagram of the transmitter and receiver for the OFDM PHY is shown in Figure 17-12. Major specifications for the OFDM PHY are listed in Table 17-16.

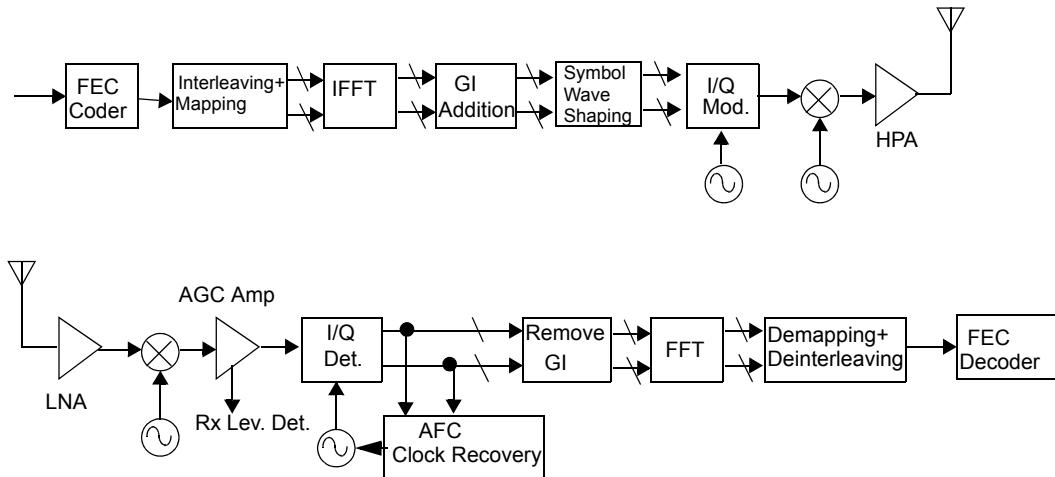

Figure 17-12—Transmitter and receiver block diagram for the OFDM PHY

Table 17-16—Major parameters of the OFDM PHY

| | | | |
|-----------------------|---|--|---|
| Information data rate | 6, 9, 12, 18, 24, 36, 48, and 54 Mb/s (6, 12, and 24 Mb/s are mandatory) (20 MHz channel spacing) | 3, 4.5, 6, 9, 12, 18, 24, and 27 Mb/s (3, 6, and 12 Mb/s are mandatory) (10 MHz channel spacing) | 1.5, 2.25, 3, 4.5, 6, 9, 12, and 13.5 Mb/s (1.5, 3, and 6 Mb/s are mandatory) (5 MHz channel spacing) |
| Modulation | BPSK OFDM QPSK OFDM 16-QAM OFDM 64-QAM OFDM | BPSK OFDM QPSK OFDM 16-QAM OFDM 64-QAM OFDM | BPSK OFDM QPSK OFDM 16-QAM OFDM 64-QAM OFDM |
| Error correcting code | K = 7 (64 states) convolutional code | K = 7 (64 states) convolutional code | K = 7 (64 states) convolutional code |
| Coding rate | 1/2, 2/3, 3/4 | 1/2, 2/3, 3/4 | 1/2, 2/3, 3/4 |
| Number of subcarriers | 52 | 52 | 52 |
| OFDM symbol duration | 4.0 μ s | 8.0 μ s | 16.0 μ s |
| GI | 0.8 μ s ^a (T_{GI}) | 1.6 μ s (T_{GI}) | 3.2 μ s (T_{GI}) |
| Occupied bandwidth | 16.6 MHz | 8.3 MHz | 4.15 MHz |

^aRefer to 17.3.2.5.

17.3.8.3 Regulatory requirements

WLANS implemented in accordance with this standard are subject to equipment certification and operating requirements established by regional and national regulatory administrations. The PHY specification establishes minimum technical requirements for interoperability, based upon established regulations at the time this standard was issued. These regulations are subject to revision, or may be superseded. Requirements that are subject to local geographic regulations are annotated within the PHY specification. Regulatory requirements that do not affect interoperability are not addressed in this standard. Implementers are referred to the regulatory sources in Annex D for further information. Operation in countries within defined regulatory domains may be subject to additional or alternative national regulations.

17.3.8.4 Operating channel frequencies

17.3.8.4.1 Operating frequency range

The OFDM PHY shall not operate in frequency bands not allocated by a regulatory body in its operational region. Regulatory requirements for a given frequency band are set by the regulatory authority responsible for spectrum management in a given geographic region or domain. The particular channelization to be used for this standard is dependent on such allocation, as well as the associated regulations for use of the allocations. These regulations are subject to revision, or may be superseded.

In some regulatory domains, several frequency bands may be available for OFDM PHY-based WLANS. These bands may be contiguous or not, and different regulatory limits may be applicable. An OFDM PHY shall support at least one frequency band in at least one regulatory domain. The support of specific regulatory domains, and bands within the domains, shall be indicated by PLME attributes `dot11RegDomainsImplementedValue` and `dot11FrequencyBandsImplemented`.

The PHYCONFIG_VECTOR carried in a PHY-CONFIG.request primitive for an OFDM PHY contains an OPERATING_CHANNEL parameter, which identifies the operating channel. The PHY shall set `dot11CurrentFrequency` to the value of this parameter.

17.3.8.4.2 Channel numbering

Channel center frequencies are defined at every integer multiple of 5 MHz above the channel starting frequency. The relationship between center frequency and channel number is given by Equation (17-27):

$$\text{Channel center frequency} = \text{Channel starting frequency} + 5 \times n_{ch} \text{ (MHz)} \quad (17-27)$$

where

$$n_{ch} = 1, \dots, 200.$$

Channel starting frequency is defined as `dot11ChannelStartingFactor` \times 500 kHz or is defined as 5 GHz for systems where `dot11OperatingClassesRequired` is false or not defined.

For example, `dot11ChannelStartingFactor` = 10000 indicates that Channel 0 center frequency is 5.000 GHz. A channel center frequency of 5.000 GHz shall be indicated by `dot11ChannelStartingFactor` = 8000 and n_{ch} = 200. An SME managing multiple channel sets can change the channel set being managed by changing `dot11ChannelStartingFactor`.

This definition provides a unique numbering system for all channels with 5 MHz between center frequencies, as well as the flexibility to define channelization sets for all current and future regulatory domains.

17.3.8.4.3 Channelization

The set of valid operating channel numbers by regulatory domain is defined in Annex E. As shown in Figure 17-11, no subcarrier is allocated on the channel center frequency.

17.3.8.5 Transmit and receive in-band and out-of-band spurious emissions

The OFDM PHY shall comply with in-band and out-of-band spurious emissions as set by regulatory bodies.

17.3.8.6 Slot time

The value of the slot time is found in Table 17-21.

17.3.8.7 Transmit and receive impedance at the antenna connector

The impedance at the transmit and receive antenna connector(s) shall be $50\ \Omega$ if the connector is exposed.

17.3.9 PHY transmit specifications

17.3.9.1 General

The transmit specifications associated with the PHY sublayer are described in 17.3.9.2 to 17.3.9.8.

17.3.9.2 Transmit power levels

The maximum allowable output power is measured in accordance with practices specified by the appropriate regulatory bodies.

17.3.9.3 Transmit spectrum mask

The transmit spectrum mask by regulatory domain is defined in Annex D and Annex E.

NOTE 1—In the presence of additional regulatory restrictions, the device needs to meet both the regulatory requirements and the mask defined here, i.e., its emissions need to be no higher at any frequency offset than the minimum of the values specified in the regulatory and default masks.

NOTE 2—For rules regarding TX center frequency leakage levels by VHT STAs, see 21.3.17.4.2.

For operation using 20 MHz channel spacing, the transmitted spectrum shall have a 0 dBr (dB relative to the maximum spectral density of the signal) bandwidth not exceeding 18 MHz, -20 dBr at 11 MHz frequency offset, -28 dBr at 20 MHz frequency offset, and the maximum of -40 dBr and -53 dBm/MHz at 30 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 17-13. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

For operation using 10 MHz channel spacing, the transmitted spectrum shall have a 0 dBr bandwidth not exceeding 9 MHz, -20 dBr at 5.5 MHz frequency offset, -28 dBr at 10 MHz frequency offset, and the maximum of -40 dBr and -50 dBm/MHz at 15 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 17-14. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

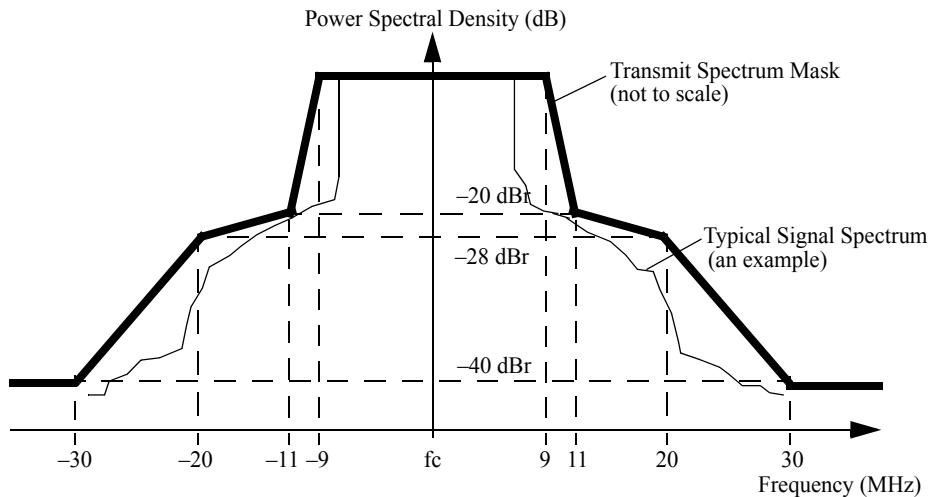

Figure 17-13—Transmit spectrum mask for 20 MHz transmission

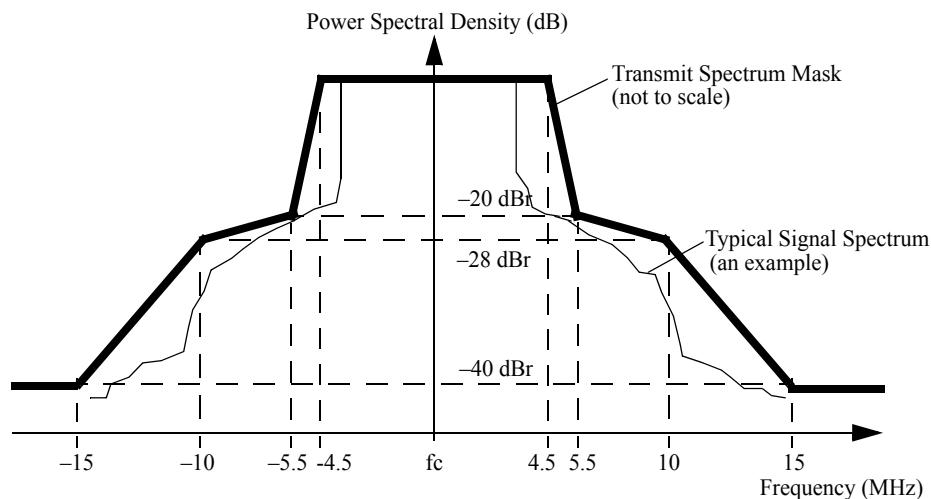

Figure 17-14—Transmit spectrum mask for 10 MHz transmission

For operation using 5 MHz channel spacing, the transmitted spectrum shall have a 0 dBm bandwidth not exceeding 4.5 MHz, -20 dBm at 2.75 MHz frequency offset, -28 dBm at 5 MHz frequency offset, and the maximum of -40 dBm and -47 dBm/MHz at 7.5 MHz frequency offset and above. The transmitted spectral density of the transmitted signal shall fall within the spectral mask, as shown in Figure 17-15. The measurements shall be made using a 100 kHz resolution bandwidth and a 30 kHz video bandwidth.

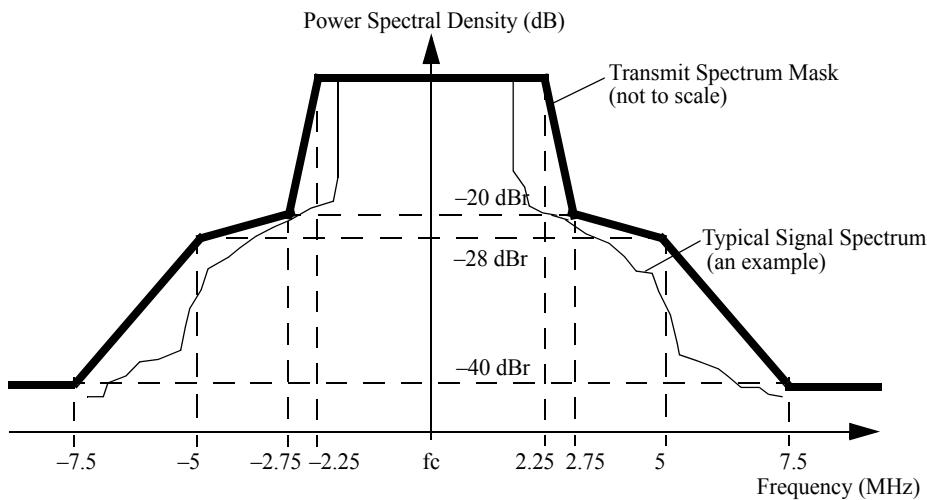

Figure 17-15—Transmit spectrum mask for 5 MHz transmission

17.3.9.4 Transmission spurious

Spurious transmissions shall comply with national regulations.

17.3.9.5 Transmit center frequency tolerance

The transmitted center frequency tolerance shall be ± 20 ppm maximum for 20 MHz and 10 MHz channels and shall be ± 10 ppm maximum for 5 MHz channels. The transmit center frequency and the symbol clock frequency shall be derived from the same reference oscillator.

17.3.9.6 Symbol clock frequency tolerance

The symbol clock frequency tolerance shall be ± 20 ppm maximum for 20 MHz and 10 MHz channels, and shall be ± 10 ppm maximum for 5 MHz channels. The transmit center frequency and the symbol clock frequency shall be derived from the same reference oscillator.

17.3.9.7 Modulation accuracy

17.3.9.7.1 Introduction

Transmit modulation accuracy specifications are described in 17.3.9.7. The test method is described in 17.3.9.8.

17.3.9.7.2 Transmitter center frequency leakage

For VHT STAs, the requirements on transmitter center frequency leakage are defined in 21.3.17.4.2; otherwise, the requirements are defined in this subclause.

Certain transmitter implementations may cause leakage of the center frequency component. Such leakage (which manifests itself in a receiver as energy in the center frequency component) shall not exceed -15 dB relative to overall transmitted power or, equivalently, $+2$ dB relative to the average energy of the rest of the subcarriers. The data for this test shall be derived from the channel estimation phase.

17.3.9.7.3 Transmitter spectral flatness

The average energy of the constellations in each of the spectral lines $-16.. -1$ and $+1.. +16$ shall deviate no more than ± 4 dB from their average energy. The average energy of the constellations in each of the spectral lines $-26.. -17$ and $+17.. +26$ shall deviate no more than $+4/-6$ dB from the average energy of spectral lines $-16.. -1$ and $+1.. +16$. The data for this test shall be derived from the channel estimation step.

17.3.9.7.4 Transmitter constellation error

The relative constellation RMS error, averaged over subcarriers and OFDM PPDUs, shall not exceed a data-rate dependent value according to Table 17-17.

Table 17-17—Allowed relative constellation error versus data rate

| Relative constellation error (dB) | Modulation | Coding rate (R) |
|--------------------------------------|------------|--------------------|
| -5 | BPSK | 1/2 |
| -8 | BPSK | 3/4 |
| -10 | QPSK | 1/2 |
| -13 | QPSK | 3/4 |
| -16 | 16-QAM | 1/2 |
| -19 | 16-QAM | 3/4 |
| -22 | 64-QAM | 2/3 |
| -25 | 64-QAM | 3/4 |

17.3.9.8 Transmit modulation accuracy test

The transmit modulation accuracy test shall be performed by instrumentation capable of converting the transmitted signal into a stream of complex samples at 20 Msample/s or more, with sufficient accuracy in terms of I/Q arm amplitude and phase balance, dc offsets, phase noise, etc. A possible embodiment of such a setup is converting the signal to a low IF with a microwave synthesizer, sampling the signal with a digital oscilloscope and decomposing it digitally into quadrature components.

The sampled signal shall be processed in a manner similar to an actual receiver, according to the following steps, or an equivalent procedure:

- Start of frame shall be detected.
- Transition from short sequences to channel estimation sequences shall be detected, and fine timing (with one sample resolution) shall be established.
- Coarse and fine frequency offsets shall be estimated.
- The packet shall be derotated according to estimated frequency offset.
- The complex channel response coefficients shall be estimated for each of the subcarriers.
- For each of the data OFDM symbols: transform the symbol into subcarrier received values, estimate the phase from the pilot subcarriers, derotate the subcarrier values according to estimated phase, and divide each subcarrier value with a complex estimated channel response coefficient.

- g) For each data-carrying subcarrier, find the closest constellation point and compute the Euclidean distance from it.
- h) Compute the RMS average of all errors in a packet. It is given by

$$Error_{RMS} = \frac{\sum_{i=1}^{N_f} \sqrt{\left[\sum_{k=1}^{52} \{ (I(i,j,k) - I_0(i,j,k))^2 + (Q(i,j,k) - Q_0(i,j,k))^2 \} \right]} }{N_f} \quad (17-28)$$

where

- L_P is the length of the packet;
- N_f is the number of frames for the measurement;
- $(I_0(i,j,k), Q_0(i,j,k))$ denotes the ideal symbol point of the i^{th} frame, j^{th} OFDM symbol of the frame, k^{th} subcarrier of the OFDM symbol in the complex plane;
- $(I(i,j,k), Q(i,j,k))$ denotes the observed point of the i^{th} frame, j^{th} OFDM symbol of the frame, k^{th} subcarrier of the OFDM symbol in the complex plane (see Figure 17-16);
- P_0 is the average power of the constellation.

The vector error on a phase plane is shown in Figure 17-16.

The test shall be performed over at least 20 frames (N_f), and the RMS average shall be taken. The packets under test shall be at least 16 OFDM symbols long. Random data shall be used for the symbols.

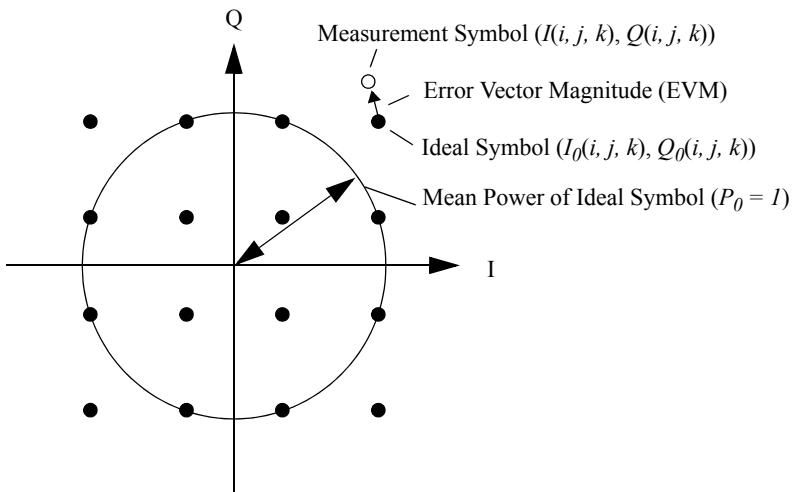

Figure 17-16—Constellation error

17.3.9.9 Time of Departure accuracy

The Time of Departure accuracy test evaluates TIME_OF_DEPARTURE against aTxPHYTxStartRMS and aTxPHYTxStartRMS against TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH as defined Annex P with the following test parameters:

- MULTICHANNEL_SAMPLING_RATE is $20 \times 10^6 \left(1 + \left\lceil \frac{f_H - f_L}{20 \text{ MHz}} \right\rceil\right)$ sample/s
 where
 - f_H is the nominal center frequency in Hz of the highest channel in the channel set
 - f_L is the nominal center frequency in Hz of the lowest channel in the channel set, the channel set is the set of channels upon which frames providing measurements are transmitted, the channel set comprises channels uniformly spaced across $f_H - f_L \geq 50 \text{ MHz}$
- FIRST_TRANSITION_FIELD is the Short symbols.
- SECOND_TRANSITION_FIELD is the Long symbols.
- TRAINING_FIELD is the Long symbols windowed in a manner which should approximate the windowing described in 17.3.2.5 with $T_{TR} = 100 \text{ ns}$ for 20 MHz channel spacing, $T_{TR} = 200 \text{ ns}$ for 10 MHz channel spacing and $T_{TR} = 400 \text{ ns}$ for 5 MHz channel spacing.
- TIME_OF_DEPARTURE_ACCURACY_TEST_THRESH is 80 ns.

NOTE—The indicated windowing applies to the time of departure accuracy test equipment, and not the transmitter or receiver.

17.3.10 PHY receiver specifications

17.3.10.1 Introduction

The receive specifications associated with the PHY sublayer are described in 17.3.10.2 to 17.3.10.6.

17.3.10.2 Receiver minimum input sensitivity

The packet error ratio (PER) shall be 10% or less when the PSDU length is 1000 octets and the rate-dependent input level is as shown in Table 17-18. The minimum input levels are measured at the antenna connector (noise factor of 10 dB and 5 dB implementation margins are assumed).

Table 17-18—Receiver performance requirements

| Modulation | Coding rate (R) | Adjacent channel rejection (dB) | Alternate adjacent channel rejection (dB) | Minimum sensitivity (dBm) (20 MHz channel spacing) | Minimum sensitivity (dBm) (10 MHz channel spacing) | Minimum sensitivity (dBm) (5 MHz channel spacing) |
|------------|-----------------|---------------------------------|---|--|--|---|
| BPSK | 1/2 | 16 | 32 | -82 | -85 | -88 |
| BPSK | 3/4 | 15 | 31 | -81 | -84 | -87 |
| QPSK | 1/2 | 13 | 29 | -79 | -82 | -85 |
| QPSK | 3/4 | 11 | 27 | -77 | -80 | -83 |
| 16-QAM | 1/2 | 8 | 24 | -74 | -77 | -80 |
| 16-QAM | 3/4 | 4 | 20 | -70 | -73 | -76 |
| 64-QAM | 2/3 | 0 | 16 | -66 | -69 | -72 |
| 64-QAM | 3/4 | -1 | 15 | -65 | -68 | -71 |

17.3.10.3 Adjacent channel rejection

The adjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table 17-18 and raising the power of the interfering signal until 10% PER is caused for a PSDU length of 1000 octets. The difference in power between the signals in the interfering channel and the desired channel is the corresponding adjacent channel rejection. The interfering signal in the adjacent channel shall be a signal compliant with the OFDM PHY, unsynchronized with the signal in the channel under test. In an OFDM PHY the corresponding rejection shall be no less than specified in Table 17-18.

An optional enhanced performance specification is provided for systems requiring improved immunity to out-of-channel interfering emissions. If a STA has dot11ACRTType equal to 2, the adjacent channel rejection shall be no less than specified in Table 17-19. The interfering signal in the adjacent channel shall be a signal compliant with the OFDM PHY, using transmit mask M (see D.2.4), unsynchronized with the signal in the channel under test. The corresponding minimum receiver sensitivities for each modulation and coding rate are the same as in Table 17-18.

NOTE—Transmit mask M is equivalent to class C (see D.2.2).

Table 17-19—Optional enhanced receiver performance requirements

| Modulation | Coding rate (R) | Adjacent channel rejection (dB) | Nonadjacent channel rejection (dB) |
|------------|-----------------|---------------------------------|------------------------------------|
| BPSK | 1/2 | 28 | 42 |
| BPSK | 3/4 | 27 | 41 |
| QPSK | 1/2 | 25 | 39 |
| QPSK | 3/4 | 23 | 37 |
| 16-QAM | 1/2 | 20 | 34 |
| 16-QAM | 3/4 | 16 | 30 |
| 64-QAM | 2/3 | 12 | 26 |
| 64-QAM | 3/4 | 11 | 25 |

17.3.10.4 Nonadjacent channel rejection

The nonadjacent channel rejection shall be measured by setting the desired signal's strength 3 dB above the rate-dependent sensitivity specified in Table 17-18, and raising the power of the interfering signal until a 10% PER occurs for a PSDU length of 1000 octets. The difference in power between the signals in the interfering channel and the desired channel is the corresponding nonadjacent channel rejection. The interfering signal in the nonadjacent channel shall be a signal compliant with the OFDM PHY, unsynchronized with the signal in the channel under test. In an OFDM PHY, the corresponding rejection shall be no less than specified in Table 17-18.
